Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE

Electrical Engineer

A Weekly Review

OF

Theoretical and Applied Electricity.

VOLUME XXIII.—1897.

(January to June.)

NEW YORK:
The Electrical Engineer
120 Liberty Street.

Alphabetical Index of Contents.

An asterisk (*) denotes Illustrations.

A Running Table of Contents will be found on the last page of each number.

LETTERS TO THE EDITOR.

American Books and English Reviewers. E. P. Thompson ... 168
Anthony, Prof., Method of Motor Speed Control. Anthony, W. A. ... 167
Arc Light Carbons and the New Tariff. Another Central Station Man ... 425
Arc Light Carbons and the New Tariff. Central Station Man. ... 502
Berliner Case, The Unsettled. J. E. Keelyn ... 568
Burglar and the Safe, More About the, Sleuth ... 295
Careless Overhead Wiring. D. W. G. ... 451
Case Hæmoglobin, or Blood Cell, The. G. V. Faraday ... 295
Cellulose Product of the Corn Stalk, The. W. W. Gibbs ... 344
Central Station Overmanned? When Is a. B. C. R. ... 294
Central Station Operation, Expenses and Profit of. W. C. Windett ... 294
Chicago School of Electricity, The. Chicago School of Electricity ... 67
Converted Steam Roads, Electrical Engineering on. Another Elec. Eng. ... 317
Danger in Pole Lines. Rand Cent. Elec. Works. ... 345
Deaf Mutes, The Morse Alphabet for. C. H. Haskins. ... 375
Duty on Arc Carbons, The. One of the Public ... 482
Electrical Manufacturers and Duty on Mica. Mica Ins. Co. ... 728
*Electromotive Force Regulation Patents on Counter. R. M. Hunter ... 167
Electrolysis, Underground Trolleys as a Prevention for. Phoenix ... 317
Enclosed Arc Lamp, The. R. M. Hunter. 250
Enclosed Arc Lamp, The. L. B. Marks. 748
English Captious Criticism. J. Trowbridge ... 66
Ether, Mental Action and the. E. J. Houston ... 265
Fire Tube Steam Boilers. Bingham Hood ... 425
Gas Engines for Electric Lighting. C. W. Andrews ... 614
Gasoline Engines and Fire Insurance. J. M. H. ... 90
Heater Switches, The Decision on. J. I. Ayer ... 344
High Duties on Carbons, Arguments for. S. B. Pike ... 482
*Hydraulics, Rankine and Weisbach as Authorities on. F. M. F. Cazin ... 568
Jandus Electric Co., The Legal Status of the. S. M. Young ... 677
Kelly Static Instrument for Detecting Grounds. J. F. Kelly ... 167
Motor Regulation Patent, The H. Ward Leonard. H. Ward Leonard ... 34
Mining Plants, Electricity vs. Compressed Air in. Lewis Searing ... 121
Motor Regulation, Prof. Anthony's Method of. W. A. Anthony ... 399
Municipal Plants. A. E. Winchester ... 249
Naval Reserve, Electricity and the. B. A. Fiske ... 295
Nicholls, Mr., Acknowledgments to the Electrical Press. F. Nicholls ... 748
Old Steam Roads, Electrical Engineering on. Western Electrician ... 375
Patent Law, The Recent Changes in the. Howson & Howson ... 317
Perrine, Dr., and the Chicago School. F. A. C. Perrine ... 145
Radiating Power of Incandescent Lamp Filaments, The. J. W. Howell ... 34
Safe Breaking by Electricity. S. Rodman, Jr. ... 222
Siemens-Halske Underrunning Trolley, The. F. B. Badt ... 145
Speed Control for Electric Motors, A New Method of. J. B. Blood ... 146
*Speed Control for Electric Motors, Anthony's Method. J. B. Blood ... 345
Sprague Electric Railway Coach, An Early. C. M. Sprague ... 399
Station Apparatus From the Manager's Standpoint. B. C. D. ... 502
Steam Railroads, Power Plant Engineering on. Electrical Engineer ... 265
Storage Batteries From Alternating Circuits, Charging. C. M. Armstrong. 482
Tampering With Meters, To Prevent. Tacoma Board of Public Works ... 205
Tariff, Arc Carbons and the New. Central Station Man ... 399
"Thermo-Electric" or Not "Thermo-Electric." C. J. Reed ... 34
X-Rays Produced by Static Machines, The Physiological Effects of. Elihu Thomson ... 35

150 HOURS

FOR 30 DAYS. INCANDESCENT LAMPS. 10% DISCOUNT.

WHY ENCOURAGE TRUSTS when you can procure from us lamps made from the highest grade stock—**CELLULOSE FILAMENT, HYDRO-CARBON JOINTS**—with **PERFECT VACUUM,** for 10 per cent. less. Our mode of pumping, together with specially prepared sealed joints, enables us to guarantee lamps not to blacken, and to show the best maintenance of candle power and life.

HIGH, MEDIUM OR LOW EFFICIENCY. We guarantee efficiency to be as ordered, and for one month will send with each barrel order our **CURRENT TESTING APPARATUS** free of charge, which will accurately show the consumption of current on any make incandescent lamp (we are glad to show the economy of ours), and solicit a trial order.

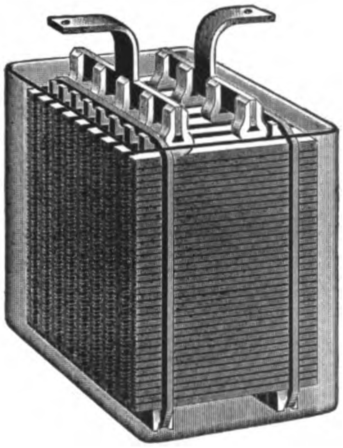
LAMP TESTING APPARATUS, with which 300 lamps can be measured in one hour on direct or alternating current, any voltage, for $1.50, cash with order.

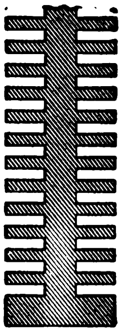
JAS. C. WORMLEY & CO., Marquette Building, Chicago, Ill

..NOTICE..

WE wish to notify the public that the claims and statements made by **THE ELECTRIC STORAGE BATTERY CO.**, of Philadelphia, that our plate infringes their patents, are **UTTERLY FALSE**, and cannot be substantiated.

The "**AMERICAN**" plate is made from a solid sheet of rolled lead, one half inch thick, grooved on both sides as shown in cut. These grooves are 1-16 inch wide, and the projecting ribs are 1-16 inch thick. This is a style of plate which **BRUSH**, in patent No. 266,090, partially described in claim No. 12, and which was afterward disclaimed by the patentee for want of patentable novelty.





The "active material" or peroxide of lead is formed electro-chemically by immersing the plate in a strongly oxidizing solution which attacks the surface of the plate and completely fills the grooves with strongly adherent peroxide of lead.

NO RED LEAD, PASTE OR OTHER MATERIAL IS APPLIED TO THE PLATE. We therefore do not infringe their patent No. 337,299.

The "**CHLORIDE**" plate of the **ELECTRIC STORAGE BATTERY CO.** is about ¼ inch thick and has for its active material pellets of peroxide of lead formed from chloride of zinc and lead. These pellets are about ¾ inch in diameter, and form about one-half the surface of the plate. In the manufacture of the latter, the pellets are arranged in a mould and a lead antimony alloy is poured around their edges.

While a plate constructed on this plan would show considerable capacity per pound weight of cell, it has no durability, as shown by the fact that the pellets disintegrate, the hard grid breaks, and the plate becomes useless after less than a year's service. After trying the "Chloride" cells for a year, the

PULLMAN'S PALACE CAR COMPANY

could not be **COERCED** into buying any more worthless material, and notwithstanding threatened injunction suits, has just placed an order with us amounting to **SEVERAL THOUSANDS OF DOLLARS.** They could not be frightened by empty threats.

Here are the names of a few of our customers most of whom have tried "Chloride" cells:

PULLMAN'S PALACE CAR CO.
PENNSYLVANIA R. R.
WESTERN UNION TELEGRAPH CO.
CHICAGO & NORTHWESTERN R. R.
CHICAGO & NORTHERN PACIFIC R. R.
CHICAGO TELEPHONE CO.
C. B. & Q. R. R.
METROPOLITAN ELEVATED.
CENTRAL UNION TELEPHONE CO.

The "**AMERICAN**" plate, as described above, has been on the market since Nov. 1st, 1895. **CELLS** constructed with these plates are in service all over the country and are giving entire satisfaction.

Not a single complaint has been received.

THE AMERICAN BATTERY COMPANY will furnish, FREE OF CHARGE, any renewals or repairs required for ANY "American" Cells sold since November 1st, 1895, where such are necessary because of deterioration of plates in service. This offer will hold good until February 1st, 1897.

The Electric Storage Battery Company **DARE** not make a similar offer.

In a short time we shall be prepared to construct and install central station batteries of the largest sizes, which will fully meet all requirements. Central Station Managers and intending purchasers of storage cells in general are requested to communicate with us before closing contracts elsewhere.

ESTABLISHED, 1889.
HIGHEST AWARD WORLD'S FAIR,
CHICAGO, 1893.

AMERICAN BATTERY COMPANY,

40 W. Quincy Street, CHICAGO, ILL.

Absolute Protection Guaranteed to Purchasers.

TRADE MARK:

"Chloride Accumulator"

REGISTERED SEPTEMBER 11, 1894.

Information, Caution and Notice!

The Courts of last resort in patent causes have repeatedly and recently sustained **BRUSH PATENTS FOR STORAGE BATTERIES,** Nos. 266,090 and 337,299, dated October 17th, 1882, and March 2d, 1886, covering broadly every practical type of storage battery plate, including not only pasted plates, but also the so-called Plante plates, in the words of **Judge Shipman** (52d Fed. 130): **"A secondary battery plate ribbed, honey-combed, studded or equivalently prepared—in which the Plante process of electrical disintegration or some kindred process of forming was used."**

In the interest of the development of the storage battery business, these fundamental or basic patents have been acquired at great expense by **THE ELECTRIC STORAGE BATTERY COMPANY,** and users, vendors and makers of storage batteries and storage battery plates are cautioned against their infringement.

To guard users, vendors and purchasers against inadvertent and unadvised infringement, notice is hereby given that the types of batteries and plates advertised by the following:

The Electro-Chemical Storage Battery Company,
The Willard Electric & Battery Company,
The Ohio Storage Battery Company,
Norwalk Electric & Battery Company,
The Warwick Electric Manufacturing Company,

WARD LEONARD ELECTRIC CO., Hoboken, N. J., U.S.A.

BOOSTERS.

All "Boosters" in which the regulating armature is driven by an electric motor, and is in a field whose magnetism can be varied independently of the E. M. F. of the regulating armature, are subject to the claims of Patent No. 572,903, issued to **H. Ward Leonard**, December 8th, 1896.

Also all commercial methods of using a reversible E. M. F. in the circuit leading to lamps, motors, storage batteries, etc., for the purpose of regulating the E. M. F. upon such devices.

All parties desiring to use or to continue using apparatus or methods covered by this patent can do so (except for certain kinds of elevators) without cost to them for past or future use of existing apparatus, by securing license from me under reasonable terms as to future use of additional apparatus which is subject to the claims of the patent, provided that they secure such license before April 1st, 1897.

Parties infringing this patent and who do not secure license before April 1st, 1897, will be held responsible as far as possible and will not be offered license on above favorable terms.

This patent has already been acknowledged as valid by many of the leading companies, among which are the **Crocker-Wheeler Electric Company**, the **Otis Bros. & Company**, and others.

A copy of the patent will be mailed upon application to any party using or contemplating the use of a "Booster."

Typical Claims.

Claim 51.—The combination with a source of electric energy, of a translating device, the armature of a dynamo-electric machine connected between the source and said translating device and running in a variable field whose strength is independent of the electro-motive force of the armature, and a dynamo-electric machine mechanically connected with said armature and electrically connected with the supply-circuit, substantially as set forth.

Claim 33.—The combination of a source of electric energy, a circuit extending therefrom, two dynamo-electric machines connected electrically therewith and mechanically connected together, one of said machines having upon its terminals a practically constant electro-motive force, and the other having a field magnetism independent of its own electro-motive force and producing a variable electro-motive force, said latter machine being connected in series with a translating device, the electro-motive force upon whose terminals is regulated by varying the electro-motive force of said latter machine, substantially as set forth.

Claim 25.—The method of obtaining from a source of electro-motive force a different and controllable electro-motive force at the terminals of a translating device with a minimum waste of energy, consisting in placing in the path of the current leading to the translating device the armature of a dynamo electric machine which is mechanically connected with the armature of a dynamo electric machine having a shunt field-winding and acting sometimes as a motor and sometimes as a generator, and operating the first-named machine as a motor to reduce the electro-motive force at the terminals of the translating device, and as a generator to raise the electro-motive force at the terminals of the translating device, substantially as set forth.

H. WARD LEONARD, — HOBOKEN, N. J.

INCANDESCENT LAMPS, DON'T be buncoed into making a contract for your supply of lamps.

"JUST TELL THEM THAT YOU SAW US."

We will furnish you with our HIGH GRADE **"O.K." LAMPS** any voltage, any base, at a lower price than you can secure by making any contract; and we GUARANTEE EVERY LAMP. We have yet to receive a complaint from a single customer. It will pay you well to write us when in the market.

Interesting Statements.

DECLARATION: Every open competitive test of Incandescent Lamps that is made results in the triumph of the IMPERIAL. (Start one yourself.)

DECLARATION: The IMPERIAL is the only independent incandescent lamp used extensively by large Central Stations. (These are the careful buyers, who, having facilities for proper tests, purchase what is cheapest in the end.)

DECLARATION: The two largest Street Railway Systems of the country purchase IMPERIALS exclusively. (40 per cent. longer life than the best competitor on rough railway work—no rigid anchor.)

DECLARATION: There is a reason for all this, for every operation during the manufacture of the IMPERIAL lamp is as surely checked as though it could be gauged. We are specially pleased when our competitors tell how expensive the IMPERIAL is to manufacture.

BRYAN-MARSH COMPANY,

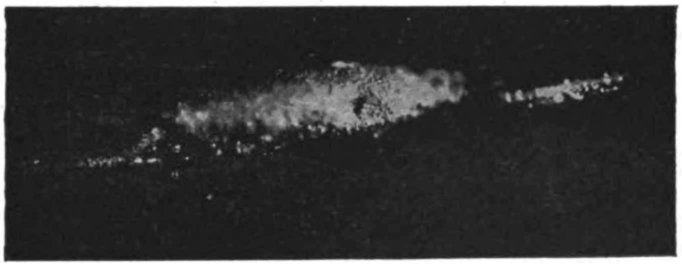
OFFICE:
136 Liberty St., NEW YORK.

CONVERSE D. MARSH, President.

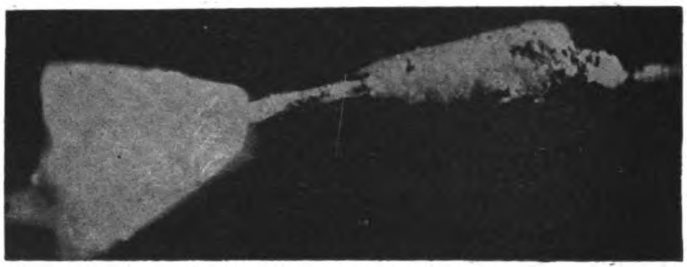
FACTORY:
MARLBORO, MASS.

By the Aid of the Microscope

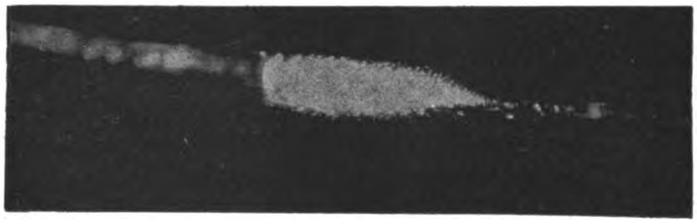
We show on this page some interesting photographs (enlarged 30 diameters) of details of lamp parts, illustrating striking differences between poor and good lamps.



No. 1 illustrates a paste or cement joint (new) connecting the platinum to the filament. Used on the majority of lamps sold. It is the cheapest and easiest to manufacture.



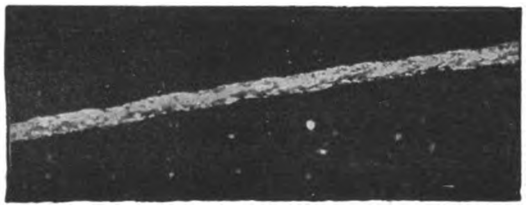
No. 2 is the old paste joint. The volcanic craters show where the gas has escaped, blackening the globe and reducing the c. p. of the lamp.



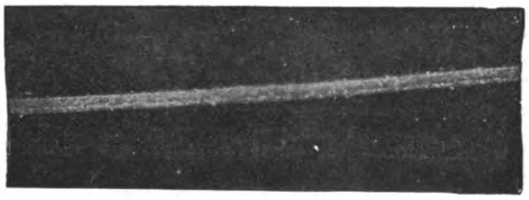
Here is an old Imperial joint—an extremely hard test, as it is a 50 c. p. lamp—the filament first socketed in a platinum sheath, and then covered electrically with pure carbon, remaining unchanged through the life of the lamp.

A Microscopic Lesson on Filaments.

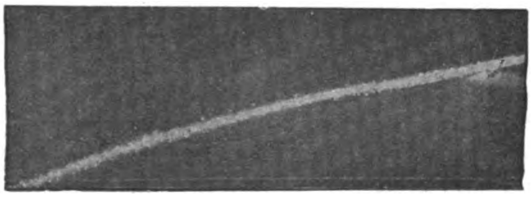
A striking sermon can be preached on filaments by examining actual examples taken from different makers' lamps.



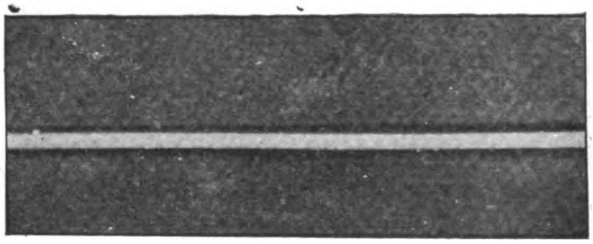
No. 1 shows a very cheap American Lamp.



No. 2, one of a little better quality and price.



No. 3 is from a standard lamp on the market.



No. 4. From a regular Imperial lamp. A flawless filament, with a polished, silvery surface, gives ideal results in economy, and in connection with the highest vacuum produces greatest sustained brilliancy and life.

BRYAN-MARSH COMPANY,

FACTORY:
MARLBORO, MASS.

CONVERSE D. MARSH, President.

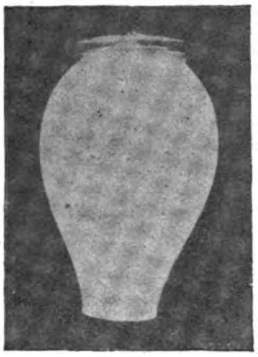
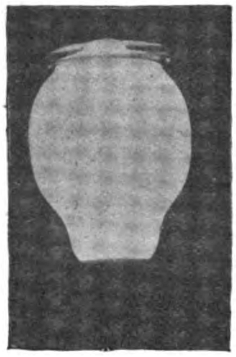
No. 6. Domestic.



No. 7. Domestic.



No. 8. European.

The Vacuum in Lamps.

A poor vacuum appears as a blue fluorescent light when an incandescent lamp is suitably connected to an induction coil for the test.

The better the vacuum the less the glow in the lamp. This means economy—life—brilliancy in an old lamp.

Poor vacuum insures short life--poor economy--blackening and rapid drop in candle power.

No. 1 shows the Bryan-Marsh Imperial Lamp.

Nos. 2 to 8 are the others; some of them contain gas enough to inflate a foot-ball.

No. 1 ***made no record on the photographic plate*** until subjected to more powerful electrical influence than its neighbors, and after twice the length of exposure.

The ***vacuum*** and the ***filament*** form the most important elements in an incandescent lamp. We offer you the best modern results in both particulars for as low a price as such quality can be sold when made in the largest quantities.

THE IRON ARMORED

OF

INTERIOR CONDUIT

NEW

IS THE ONLY

We offer the only complete system of electric wiring.

OUR NEW STANDARD IRON ARMORED INSULATING CONDUIT

is far superior to any ever placed upon the market, possessing advantages in that it is extremely light, has a smaller outside diameter for a given inside diameter, and moreover has greatly increased insulating properties. THE INSULATING LINING, BEING OF A FLEXIBLE NATURE, IS NOT AFFECTED BY BENDING, and the insulation under such conditions is not impaired. Like all other standards, this material will probably be imitated. However, the broad, fundamental patents covering the process of manufacture prevents even a near approach to the features wherein lie the strength and integrity of insulation possessed by our

"The ELECTRA"

ELECTRA
·TRADE MARK·

For Direct Current
For Alternating Current
For Enclosed

**Arc....
Lamps**

THEY are unsurpassed for even and perfect combustion.

They produce practically no dust, and are therefore more completely consumed, thus giving a longer life than any other carbon.

They give an excellent, uniform, brilliant and steady light.

They produce the highest standard candle power in proportion to the current consumed, and are therefore the most economical carbon manufactured.

The leading electric light stations who have tested the "ELECTRA" CARBONS, and have since adopted them exclusively for their arc lighting, admit their superiority over any other high grade carbons.

WESTINGHOUSE ENGINES.

ALL REPUTABLE ENGINE BUILDERS will guarantee the material workmanship, capacity and economy of their engines. If material is defective, it will be replaced; if the workmanship of any part is not up to standard, it will be made good. There is a chance that the engine may not develop its rated power, but that is not so probable, since the capacity of an engine is simply a measure of cylinders, piston speed and steam pressure.

The question of economy, however, is the stumbling-block. After an engine has been installed and fails to show the **guaranteed economy** the purchaser has no recourse except to take the engine out. If he decides to do this, it means interrupted business and serious inconvenience, aside from the direct expense involved. The consequence is, that it is seldom or never done.

Every engne we build has a record **before leaving the shop**, based on a rigid economy test. Any purchaser so desiring may have his engine tested by his own expert at our shops before shipment, and may accept or reject the engine on that test, before incurring the expense of installation.

EDISON FLUOROSCOPES

Our Fluoroscopes and Fluorescence Screens are of acknowledged superiority and are used by the more prominent X-Ray investigators.

Our Photographing Screens are coming into general use in X-Ray surgery.

OUR FLUOROSCOPES are tasteful in design; they are provided with flexible and close-fitting eye-pieces, which makes it possible to use them in a lighted room, and are as light in weight as is consistent with the strength of frame necessary to protect the screen. The screen is the result of careful experimenting with crystals of different sizes and applied in varying quantities. The method of supporting the crystals has received special attention; after thorough tests of paper of different kinds, card boards, woven cloths, aluminum foil, etc., as mounts for the crystals, we have adopted that which proved best for the purpose.

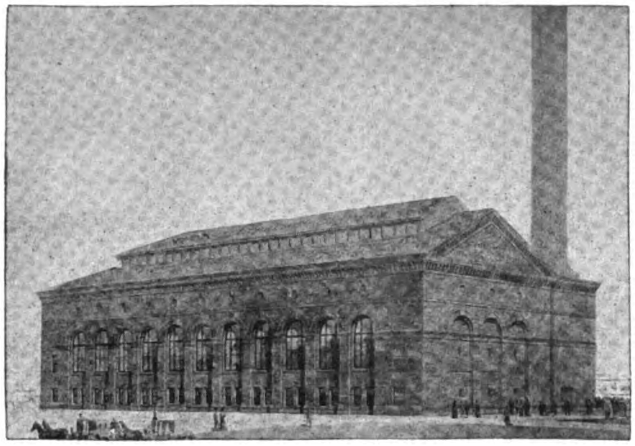
ELECTRIC TRANSPORTATION

THE COMBINATION LIGHTING AND RAILWAY PLANT OF THE TOLEDO, O., TRACTION CO.

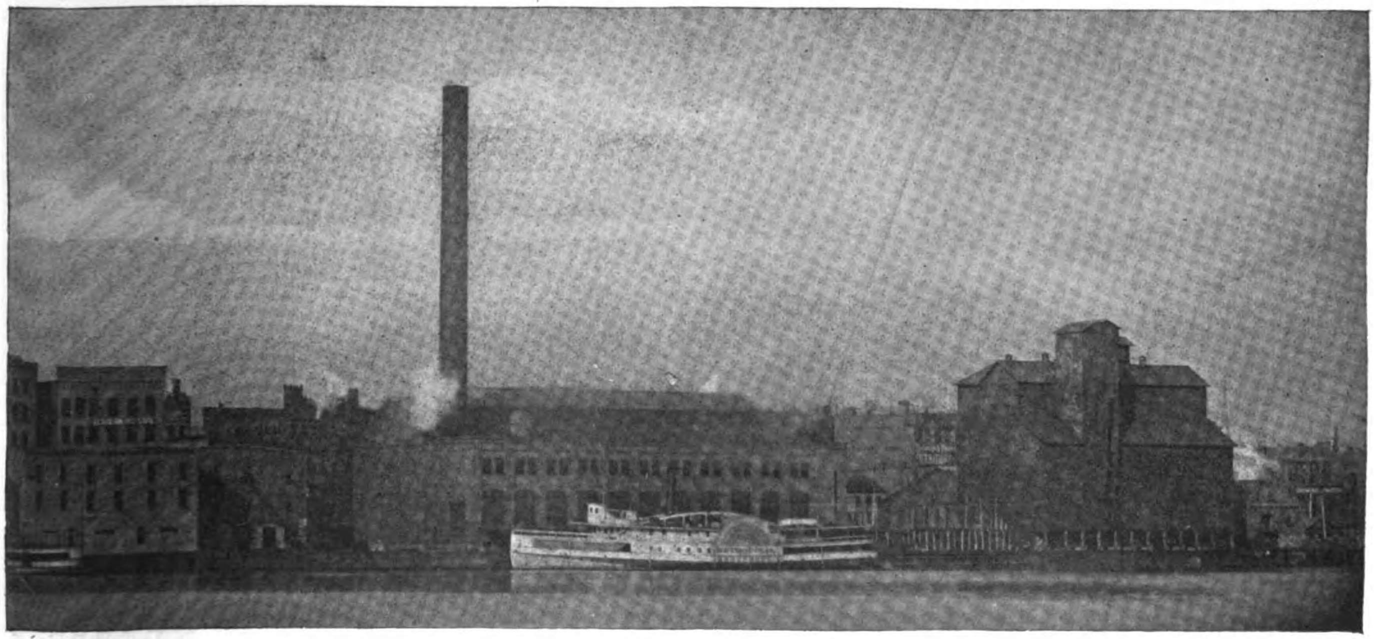
FEW, if any, cities in the Central States have had a more rapid growth than Toledo, O. The census of 1890 credited the city with a population of 81,000. At the present time it is about 120,000, and gives every indication of large and steady gains. A visit to the city reveals advance and activity on every hand, and the enterprise of the people creates daily new opportunities for expansion or investment. Under such circumstances, it is natural, one might even say inevitable, that the lighting and street railway systems should have undergone rapid changes and that the original plants should have proven inadequate to the needs of the present hour. It was difficult, however, to secure new capital in any bulk unless it could be in some degree protected from undue competition, and this state of affairs led to the formation of the Toledo Traction Company, which by consolidation and merger represents the various interests formerly owned and operated by the Toledo Consolidated Street Railway Company; the Metropolitan Street Railway Company of Toledo; the Central Street Railway Company; the Ironville Street Railway Company; the Toledo Electric Railway Compauy, and the Toledo Electric Street Railway Co. This imposing aggregation of properties is capitalized to-day for $2,000,000 in preferred stock, $4,000,000 in common stock and $5,000,000 bonds, the latter a first-mortgage 5 per cent. issue, now being made, which retires all other bonds except $2,000,000 which are met by these new bonds to an equal amount held in the hands of the trustees. More interesting, however, from the strictly engineering point of view are the details of the plant and system, which to-day has to earn the fixed charges of $254,000, and promises to earn this year nearly twice that amount in addition, net, for the stock. Mr. N. B. Ream, the well-known Chicago capitalist, is president of the company, and furnishes the data given above.

The company owns and operates all the street railways in the city of Toledo, comprising about 120 miles of single track, completely covering the entire city and in some cases extending beyond the city limits into suburban localities. The entire system is operated by trolley, having been completely equipped during the past few years. The equipment consists of 119 closed cars, 100 open cars, 29 trailers, 284 motors, 5 snow ploughs and about 147 trucks, all of modern construction and in good order.

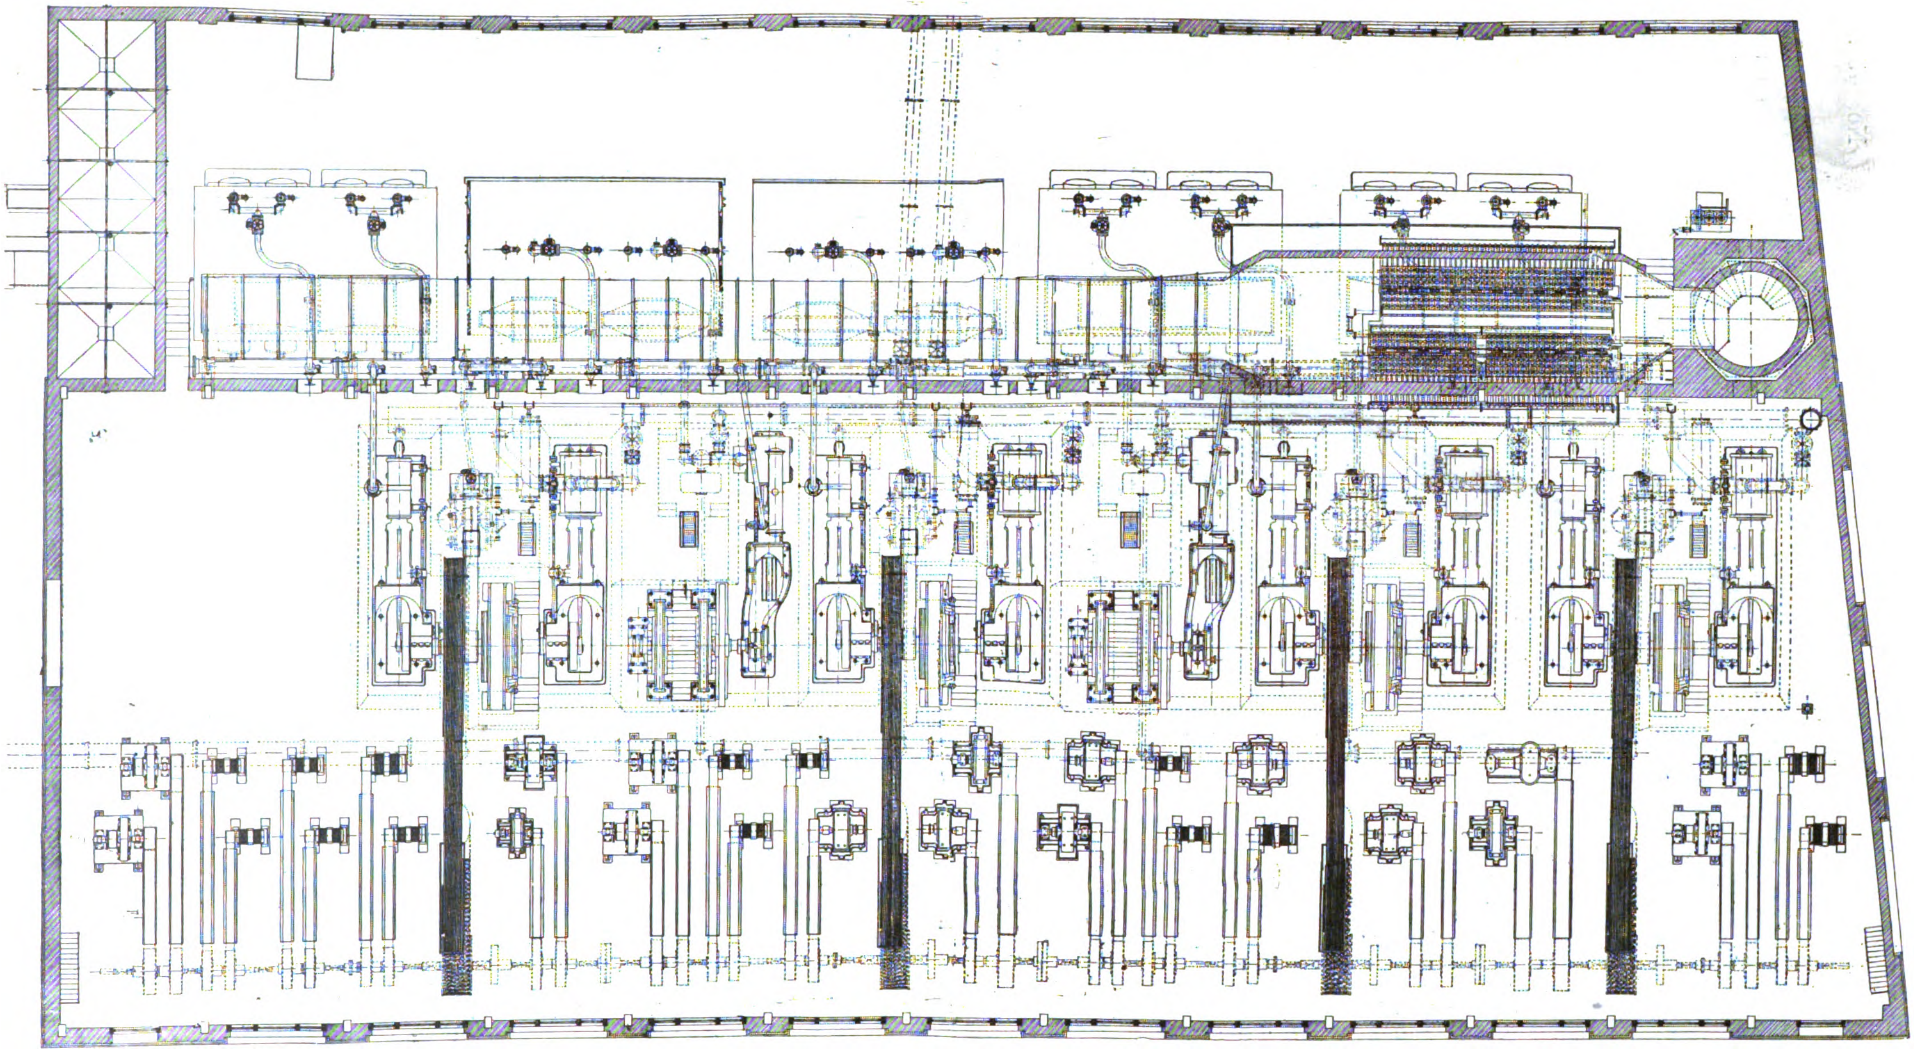


NEW POWER HOUSE, TOLEDO TRACTION CO.

All of the track has been rebuilt within the past five years with heavy girder and "T" rails and the best quality of oak ties, averaging about 2,600 to the mile. The streets on which the tracks are located are for the most part substantially paved with stone, brick, asphalt, and wood pavement. The overhead construction is well built and in good order and condition, and the entire plant is properly equipped with the most improved type of machinery and apparatus.



NEW POWER HOUSE, TOLEDO TRACTION CO. FROM THE MAUMEE RIVER.



Plan of Generating Plant, New Power House,

Toledo Traction Co.

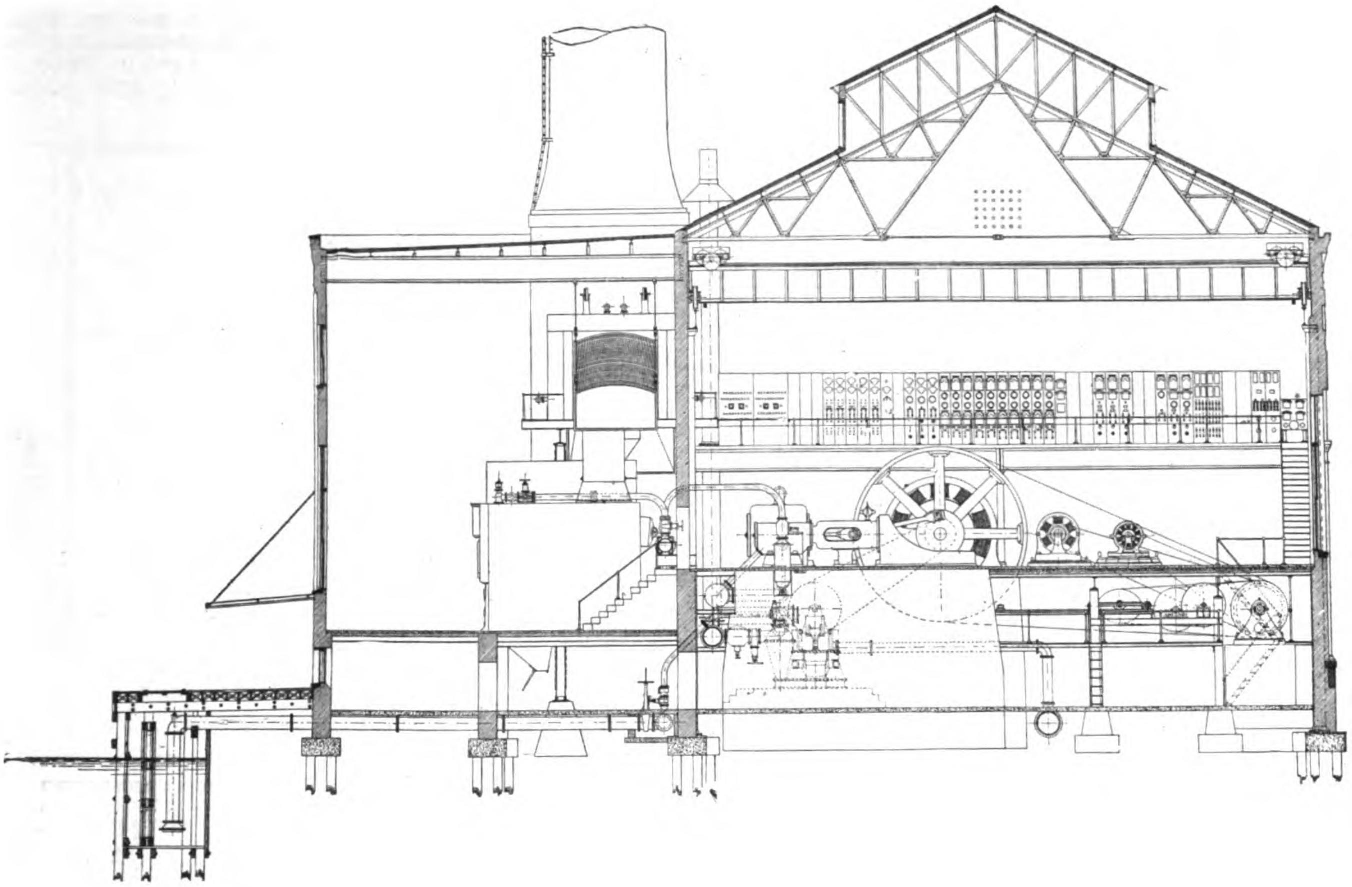
The company has just completed a new fireproof power station, located on the Maumee River, in the center of the city, its size being 212 feet on Water street and 115 feet on Monroe street, extending to the river bank, from which water is taken for condensation purposes. It has more than as much additional land adjacent to this station, available for any extensions which may be desirable in the future. This station is equipped with American Wheelock-Greene engines, General Electric direct connected generators for railway and power service, Fort Wayne generators for arc lighting, Westinghouse generators for alternating lighting, and the Edison generators for the three-wire system for its underground circuits for power and lighting.

The companies have a contract with the city of Toledo for lighting the streets which does not expire until January, 1900.

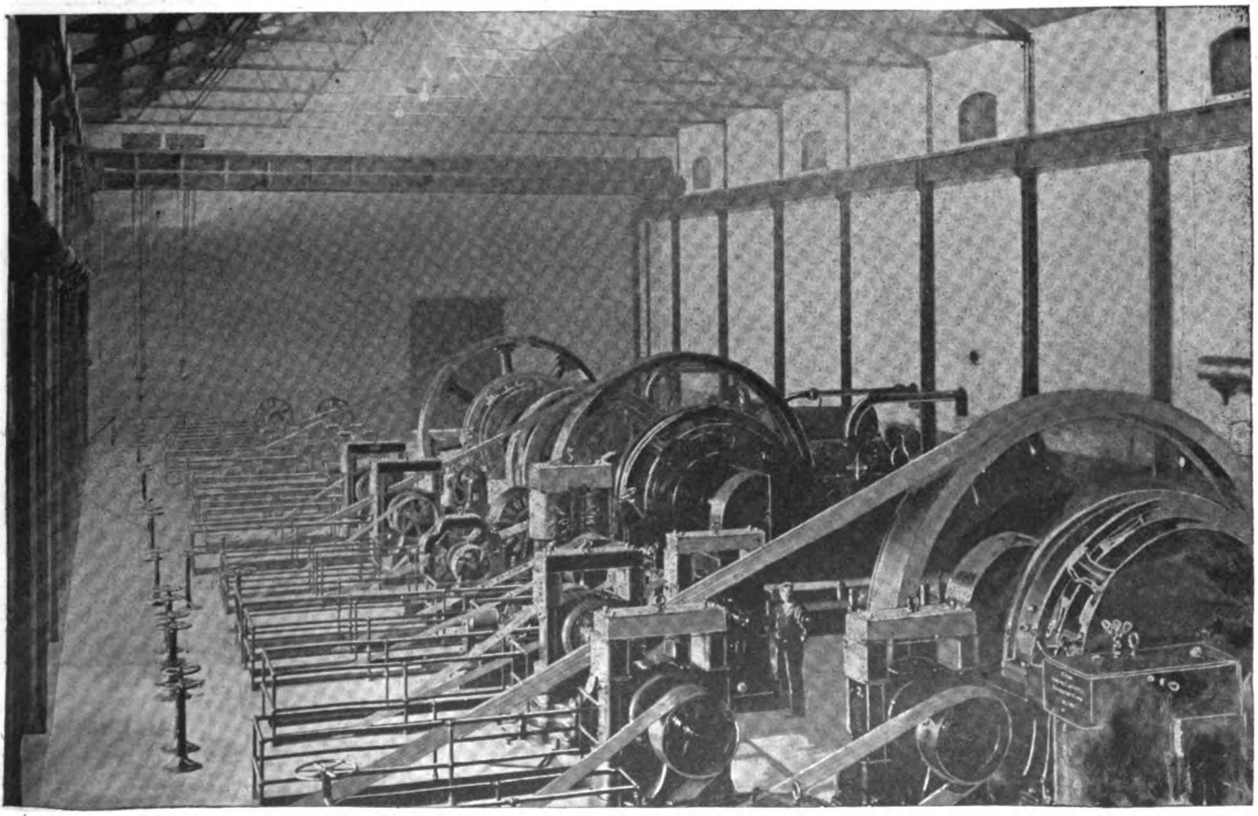
The business of the company is as follows: City arc lights, 719; commercial arc lights, 304; incandescent lights, 30,578; motors, horse-power, 923.

The entire system, railway, incandescent and arc lighting, and power, is operated from this new central station, and the variety of the service enables a good load to be maintained and utilized during the entire twenty-four hours, thereby giving the highest efficiency with the greatest economy.

In addition to this station the company has two smaller ones, which are held in reserve, located on the Maumee River and equipped with modern apparatus for the economical production of electric current.

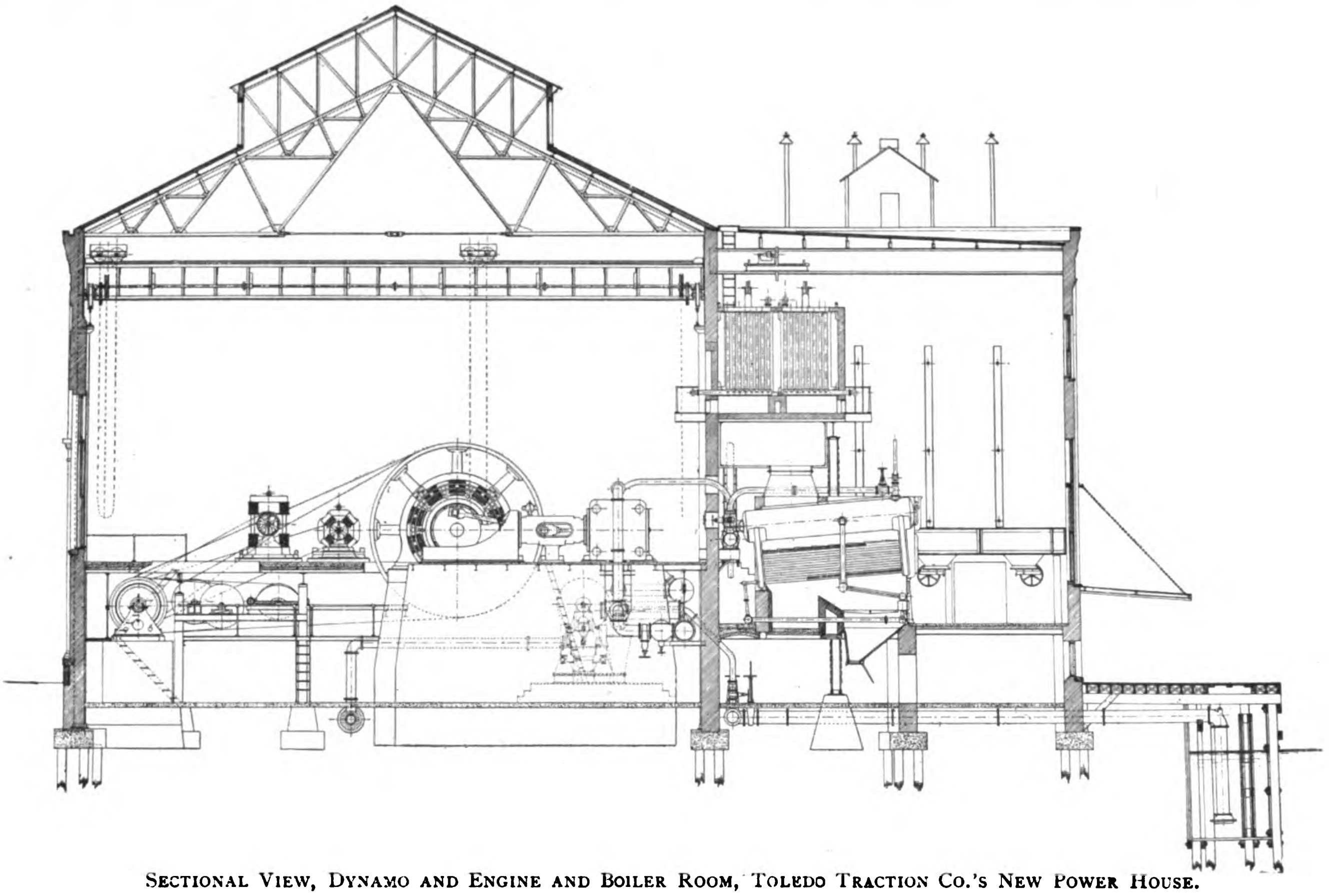


SECTIONAL VIEW, TOLEDO TRACTION CO.'S POWER HOUSE.

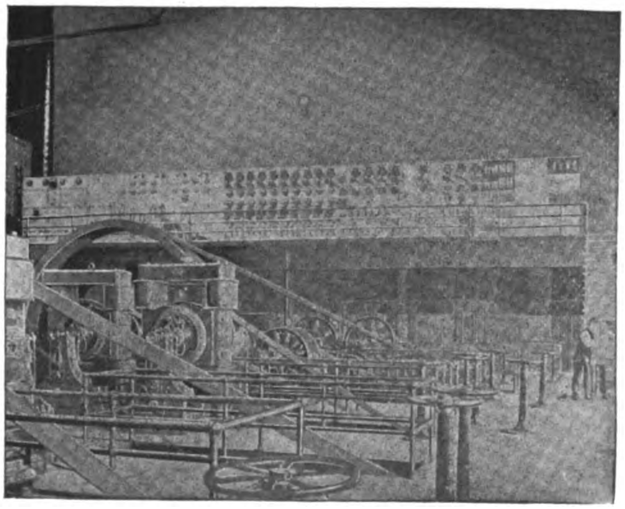


LIGHTING AND RAILWAY PLANT, TOLEDO TRACTION CO.'S NEW POWER HOUSE.

The Toledo Traction Company, through the Toledo Consolidated Electric Company and the Western Electric Light and Power Company, controls, with the exception of the business of one small company, all the electric lighting, public and private, and power business in the city of Toledo. The franchises are perpetual and the Toledo Consolidated Electric Company has also a perpetual franchise for subways and conduits extending over the entire city which it has installed throughout the business district. Into these conduits are placed the feeders for the railway and lighting circuits, and with them are connected the entire underground system for the lighting of the central portion of the city and for the distribution of power. During the present year all the poles in the business district now used for supporting wires for the transmission of power for lighting and otherwise, except for the support of the trolley wires, will be removed.

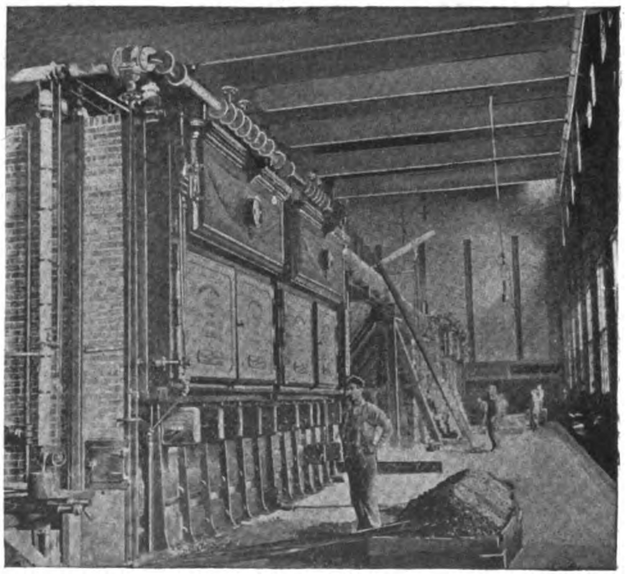


Sectional View, Dynamo and Engine and Boiler Room, Toledo Traction Co.'s New Power House.



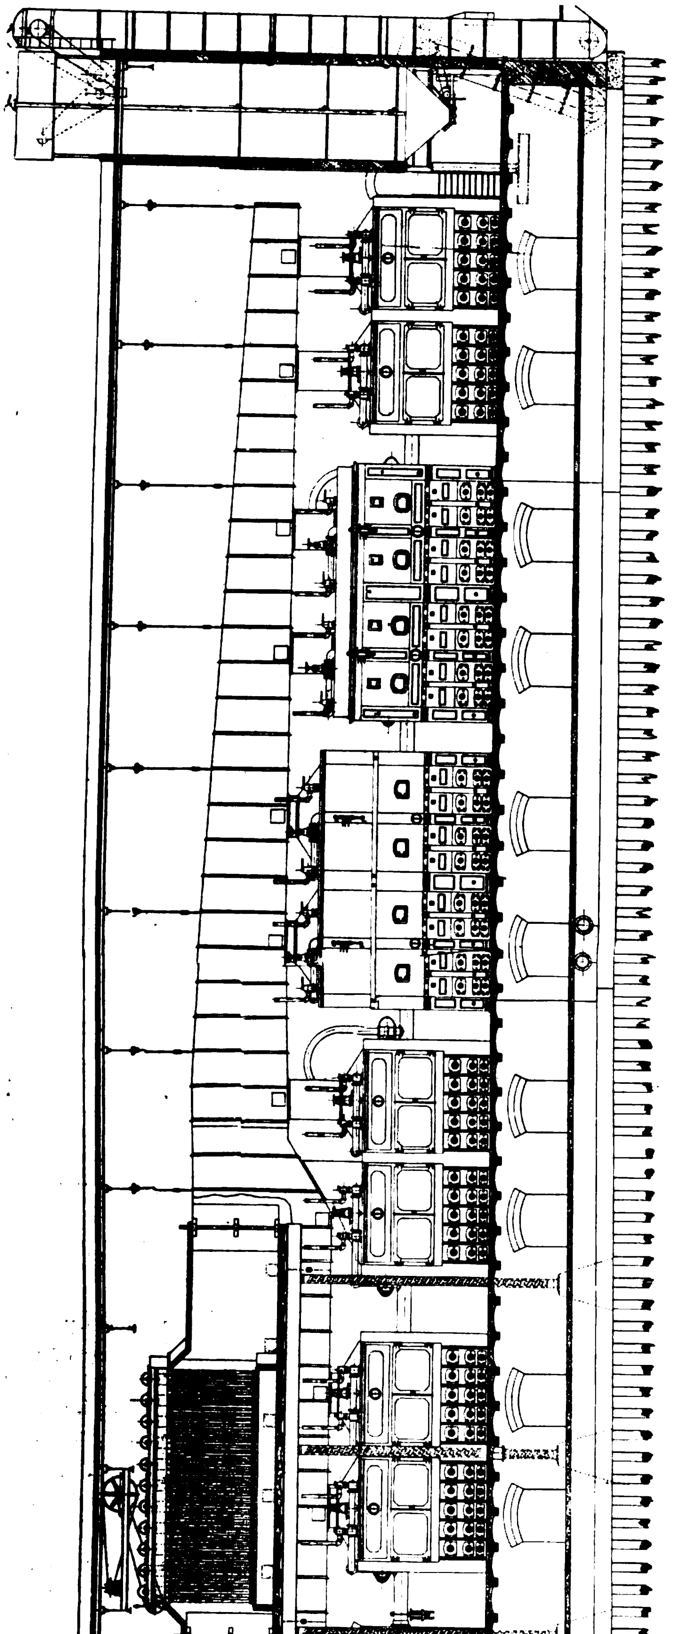
Switchboard and Lighting Generators, Toledo Traction Co.'s Plant.

The new power plant, to which reference has already been made, and of which several perspective and diagrammatic views are shown in these pages, is a fine building, 212 feet by 116, the engine room being 208 feet by 70 and the boiler room 208 by 38. The building is steel frame, with brick walls and slate and tile roof. The foundation is of spiling in the river bank, with concrete and brick. The smoke stack is of steel, 213 feet high, 13 feet inside diameter, lined with fire brick and tile. The building was designed by D. H. Burnham & Co., of Chicago, and the Ohio and Toledo Bridge Company were the contractors for the steel work. Mr. Frederick Sargent, of Sargent & Lundy, Chicago, was the consulting engineer for the electrical and steam engineering work.



View in Boiler Room, Toledo Power House.

The steam plant consists of four American Wheelock en-



Plan of Boiler Room, Showing Economizer. Smokestack, Coal Hoisting Apparatus, Etc.

gines, cross-compound, and two Porter-Allen tandem compound. Owing to the peculiarly miscellaneous nature of the work, resort has freely been made to shafting, the lighting generators on the engine room floor, for example, being belted to the line shaft in the basement. There is 172 feet of Hammond turned wrought iron shafting, with three friction clutch couplings, and Hill Clutch Company's clutches on all pulleys and quills. The boiler plant comprises four 500 horse-power Heine boilers, four 300 horse-power Stirling, two Hawley down draft furnaces, six McKenzie furnaces, and the Green fuel economizer. The coal handling machinery was furnished by Borden & Sillick Co., the crane 20-ton hand power, by the Brown Hoisting Company, of Cleveland. The piping is covered with sectional magnesia. The gate valves are the Chapman make, and the injectors are the Penberthy, while the jet condensers are of Blake and American-Wheelock make. There are four direct belted pumps of Cramp make and two Blake steam pumps.

In the dynamo room the switchboard is of General Electric Company's construction, and a large number of the Weston instruments are used on it. It is of Italian marble, handsomely finished. The wires and conductors in the house are rubber covered, and carried on porcelain insulators.

Special interest attaches to the newer engines in this plant. There are four 1,200 horse-power Greene-Wheelock engines furnished by the American Wheelock Engine Company, of Worcester, Mass., where the valve gears are built; the other parts of the machinery, including the pumping mechanisms, were built by the William Cramp & Sons Ship and Engine Building Company, Philadelphia, Pa.

These engines were guaranteed while running 90 r. p. m. and developing 675 horse-power each with 150 lbs. pressure to show an economy of 13 lbs. of steam per horse-power hour, regulation to be within 2 per cent. from minimum to maximum load. The dimensions of cylinders are 24 x 48 x 48, cross-compound. The fly wheels to each engine are 20 feet in diameter, grooved for fourteen 1¼-inch ropes and weigh 60,000 lbs.

The Greene-Wheelock valve gear employed in these engines has the two valves inserted in the plug, which is removable from the cylinder. The governor has full control of the cut-off from zero to ⅞ inch. In the low pressure cylinder there are eight valves employed on each end and two outlet and two inlet valves. Each valve has its own eccentric and independent adjustments in each case. The Greene segmental piston packing is used in the pistons. The frames and waists of each engine are specially designed for this plant, and are of the heavy rolling mill type. The crank shafts are 20 inches in the bearing, 36 inches long and 22 inches in the armature hub. Each engine has its own independent jet condenser, driven by a 12-inch belt from crank shaft to engine. The condenser shaft not only drives the circulating pumps, but also the boiler feed in each case. It will be noted that the dimensions of these cylinders are designed under the Rockwood Compound System, and show, as stated, triple expansion results with the use of the compound cylinders.

The electric light machinery is driven by a line shaft with friction clutches running the entire length of the building. Power is transmitted to the line shaft from each engine.

Each engine has an 800 horse-power Hoadley compound wind system transmission connected to line shaft. The Bichette manila rope is used for transmission purposes in this station, 1¼ inches in diameter. Each drive requires 3,100 feet of rope. The American system of steam distribution, patented by F. Sargent is used throughout this plant, and it is authoritatively stated that the entire cost of piping is less than one-half of any other system employed. It will be remembered by the readers of The Electrical Engineer that this steam piping system is also in use in the Chicago Edison station on Harrison street and the Chicago River.

We are indebted for many of the details given above, to Mr. Winfield S. Jewell, the general manager of the plant, and Mr. F. Sargent. Our half-tones are from photographs taken specially by Mr. G. A. Cooke, assistant to the general manager.

"WHITE FLYER" bicycles will probably be built at Niagara Falls, the company requiring about 100 electrical horse-power to run their factory of 150 men.

MATHIESON ALKALI COMPANY.—The new plant of the Mathieson Alkali Company, to be erected at Niagara Falls, will consist of several buildings covering two acres. The first section is to be completed by January 15, 1897. The company, which, as is well known, manufactures caustic soda by the Castner process, will employ 150 men and use 2,000 estimated horse-power at its new works. It already has large plants in England and at Saltville, in Virginia. At the latter plant no water power is available. A very complete electric plant for the chemical process and for lighting is installed, Westinghouse apparatus being used.

SOME PRACTICAL SUGGESTIONS FOR THE OPERATION OF LONG ELECTRIC RAILWAY LINES.

BY PROF. S. H. SHORT.

(*Electrical Engineer, Walker Mfg. Company.*)

THE saving of time effected by the rapid trolley roads in cities, suggested to railway men the convenience as well as profit, to be secured by connecting neighboring centers of population with one another in the same manner. These roads were consequently equipped and have been operated with a measure of success by apparatus designed and constructed for the slower speed and more frequent stops necessary in city traffic.

The limited experience in inter-urban traffic has already created a demand for heavier equipment and higher speed, and the public is now familiar with double truck passenger coaches equipped with motors ranging from 50 to 100 horsepower, and a complete system of air brakes similar to those used on steam railways. Several roads in this country from 40 to 50 miles in length are using trains consisting of two or three of these passenger coaches. These roads use the overhead trolley system and the cars or trains are brought into the center of the cities over the lines of the local street railway companies.

The greatest difficulty in this combination service is that apparatus required in this suburban work must be constructed to develop much greater speed than is permitted within city limits. In existing practice two motors of large size are used and regulated by an ordinary series multiple controller. If these motors are geared to run 40 miles an hour at full speed on the parallel position of the controller, their minimum speed would be 20 miles per hour, on the series position, unless considerable rheostat resistance be included in circuit, which is both wasteful of energy and destructive to the resistances themselves.

I would therefore suggest a method which I consider preferable, that is, the using of four smaller motors, one on each axle of the motor car. With these a controller should be provided which, when grouping the motors in parallel will develop a speed of 40 miles an hour, in series parallel a speed of 20 miles an hour, and in series, a speed of 10 miles an hour. The latter is the maximum speed permitted in city streets at present.

One distinct advantage obtained by the use of four motors is the increased tractive effort due to the adhesion of double the number of wheels to the rails. All practical street railway men are familiar with the difficulty of producing sufficient tractive effort with large double truck cars, even without a train attached. It is useless to attach to the axle of the car a motor which will have a greater horizontal effort than one-fifth the weight supported by that axle, and its pair of wheels.

With the increased speed and weight of trains there is a proportional increase in the amount of power used, which means the consumption of large quantities of current drawn from the trolley wires overhead.

There being but a small point of contact between the wheel and its overhead wire, the trolley now in use has reached its limit in current carrying capacity, therefore it is necessary to improve upon the present method of taking current from the supply conductor. This may be done in several ways. Two or more trolleys may be arranged, one behind the other, and connected in parallel, each taking its portion of current from the trolley wire; or perhaps better, a single trolley with a cylinder of some length attached to the upper end of the trolley pole, making contact with two or three current carrying trolley wires. These trolley wires would be connected in parallel and would reduce the size of the feeders of the line. Over switches and sidings these wires could be separated, as one wire would carry sufficient current for any short distance.

For long distance roads which pass beyond the class of interurban street railway and become in reality cross-country roads on which the equipment must be as heavy and durable as that of steam railways, and on which several hundred will be required to operate trains, the overhead trolley system is, in my opinion, impracticable. A feasible and entirely practical method would bring into use again a third rail. This rail might be supported at one side of the track and protected by a sufficiently complete conduit, current being passed to the moving train through contact shoes, attached to the front and rear trucks of the motor car. This rail should receive its current from a main extending the full length of the road. As has been said before, it would be necessary to provide these fast trains with a very complete air brake system operated by independent motors. It is generally conceded to be unwise to use a current of more than 600 volts for street railway purposes.

Because of the fact that the starting torque or effort of the direct current motor is so great, a direct current has been used almost exclusively up to the present time. The increased mileage of several important lines of railway already planned will prohibit the use of the direct current system because of the initial cost of the copper conductors. The alternating current has already replaced the direct where water power within reasonable distance is available, and is undoubtedly a solution at least in part of the difficulties which have been outlined. It is true that at present the use of the alternating current forces upon electricians all the difficulties of an original adaptation. The necessity for step-down static transformers and rotary converters with their indispensable care-takers at frequent intervals along the line, to convert the currents of 10,000 or 20,000 volts into direct currents of the ordinary pressure still exists, and forms a serious but not insuperable objection to its use. I consider the use of alternate current motors imperative, as by receiving the current directly from the static step-down transformers, they render the use of the rotary converters unnecessary.

While alternating motors work with entire satisfaction after they have attained their normal speed and synchronize perfectly, they cannot as yet be depended upon to furnish the necessary starting torque. This defect has, however, been in part overcome by recent efforts and the subject is having close and intelligent attention from practical electricians. The speed of the alternating motor can be accurately regulated, since on the various sections of the road the supply conductor can be fed with exactly the number of alternations per minute necessary, to produce the speed required there, and the ascent and descent of grades will be accomplished with equal facility.

It is probable that we are in the end to discard both these practical and financially successful methods or operating railways for a third, which, according to recent public announcements of experiments carried on through several years past, seems to be almost within our reach. The conversion of the potential energy of carbon into electrical energy is already an accomplished fact and its application to the problems of street railway service is but a question of time. When the special apparatus has been devised and we are able, in the comparatively small space of a motor car to convert coke directly into electrical energy without heat or smoke and transmit that energy to motors attached to the car axles, it would seem that engines and dynamos, supply conductors, and even trolleys themselves, will no longer be necessary.

Little will be left in fact of the present equipment, but the fine roadbed, which it is now regarded as the best economy to construct. Laboratory experiments in direct conversion of coal into energy emphasize the fact that our practical mechanics, in being satisfied to obtain from a pound of coal but one-fifth of its value in force, have exacted too little.

The possibility of approaching theoretical efficiency, which the adaptation of direct conversion to our street railway service would seem to bring within our reach, already makes the boasted economy of our Niagara systems little less than wasteful expenditure.

THE TROLLEY IN INDIA.—THE MADRAS ELECTRIC RAILWAY.

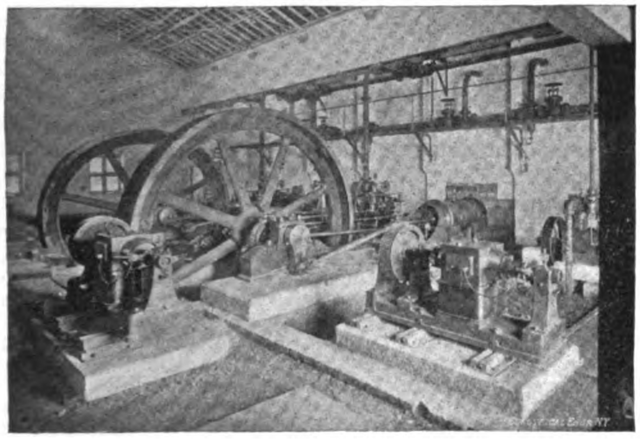
BY GEORGE HELI GUY.

IT would seem one of the anomalies of modern civilization that Madras, the capital of the Indian Presidency of that name, of whose 452,000 inhabitants, 411,000 are Hindoos and Mohammedans, should have its electric road, while New York, the metropolis of the Western Hemisphere, is still running horse cars in its streets.

Two years ago, Madras, whose local passenger transit facilities had been limited to ramshackle cabs, sedan chairs, and bobtail horse cars, was invaded by the operations of the Madras Electric Tramways Company, who laid a conduit to connect important sections of the city. The line was laid down the center of one of the main business arteries, and thus resulted in two collateral advantages much appreciated by the 13,000 Christians of the city. It necessitated the regular repairing of the road, which before then had been almost entirely neglected, and it compelled the street traffic, which consisted mainly of ox-carts, sedan chairs, and mules, to follow the "rule of the road," instead of being perpetually in a state of noisy confusion from the collision of its up and down streams. But the monsoons and the jutkawallahs were too much for the electric conduit in its new sphere. When the heavy tropical rains came down, the conduit would be flooded, sometimes with over a foot of water, and no drainage provisions were adequate to altogether overcome this difficulty. The jutkawallah, the native driver of the indigenous shandrydan, a picturesque vehicle drawn at a snail's pace by a misanthropic looking steed, had bitterness in his heart for the swiftly moving car that swept away his living, and endless short circuits vexed the soul of the road superintendent, who would occasionally discover bars of iron and other such trifles jammed viciously into the conduit.

The consequence was that the trolley was brought into requisition on the second and third sections of the line, which, when completed, were nearly ten miles long. There was, of course, trouble and delay in the changing of passengers from one system to the other at the junction of the first and second sections, and it was finally decided that the natural way to smooth and uninterrupted operation and peace of mind was to make the system uniform; and steps are now being taken to supersede the conduit by the trolley on the first section. It is expected that this change will add considerably to the receipts of the road, as the native East Indian is averse to exertion, and blind to the charms of the transfer system, and many a fare was lost from the fact that the passenger could not make the whole trip of the line without the necessity of leaving his seat.

In fact, for a while, the task of breaking in the natives to ride in cars at all baffled the ingenuity of the management. The Hindoos blankly refused to ride with the Mohammedans, and the deadlock threatened to be serious. By a happy thought a lottery system was started. The passenger had a ticket handed to him in exchange for his fare, and the ticket bearing a certain number took a prize. The temptation to make a few annas was too much even for blood prejudices, and now Hindoos, Mohammedans, Parsees, Portuguese, and Europeans throng the cars indiscriminately.



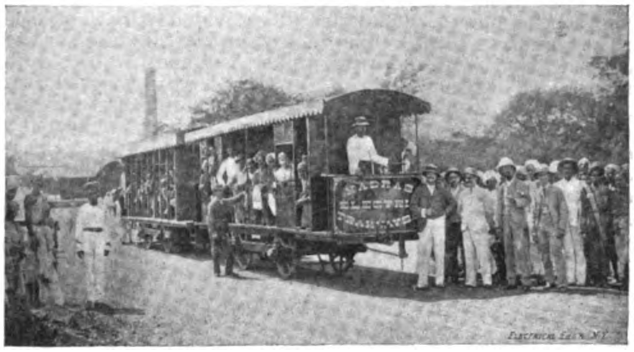
Power House, Madras Electric Railway.

The resources of the Madras line are to be further increased by the establishment of a service to dispose of the city garbage. Under the concessional order of the company provision was made for the construction of a rubbish line, for conveying the refuse of Madras to an outlying district, which the company, if called upon, had to complete by a given time. The municipality has at length availed itself of this option, and arrangements have been made for the early construction of the supplementary line. It is not unlikely that the growing passenger traffic may soon necessitate further extensions. The popularity of the tramway is shown by the fact that although only a limited number of cars are in use, a considerable revenue, over 400 rupees (about $150) a day, is being earned. The large number of passengers that are daily unable to ride for want of sufficient accommodation warrants the assumption that when the full earning capacity of the line is available, the returns will, in all probability, be doubled.

The capital of the company is £100,000, of which about £70,000 has been issued. Very low rates of fare are charged. The fare is fixed by concessional order at one half-anna per mile. Sixteen annas equal one rupee, and the present value of the rupee is about 28 cents.

The line was equipped by the Electric Construction Company, of London. The station contains two coupled compound non-condensing engines of the Burnley Iron Works Company's make, capable of developing 180 to 225 horse-power, at about 90 revolutions per minute, fitted with grooved fly wheels for rope driving. There is also a vertical Belliss high-speed engine for lighting, capable of working up to 20 horse-power. at 320 revolutions per minute, fitted with rope-driving flywheel. The power generators are two shunt wound Electric Construction Company dynamos, each capable of giving an output of 120 kilowatt (240 amperes, 500 volts), rope driven. The lighting generators are two 12 kilowatt E. C. C. dynamos, of the same make, equal to 200 16-candle-power lamps, and rope driven.

The car motors are of the two-pole type, wound for 500 volts.



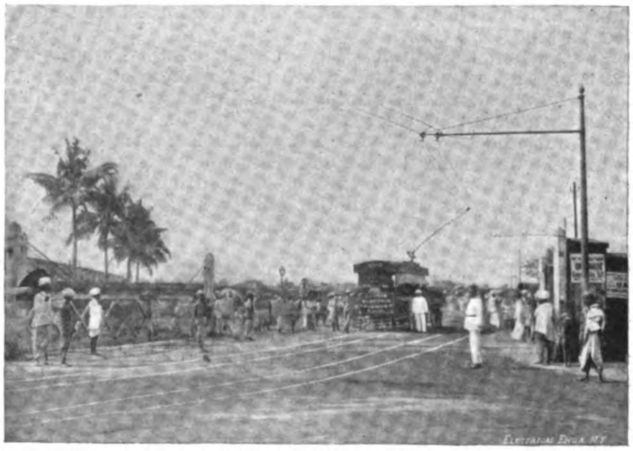
Motor Car and Trailer, Madras Electric Railway.

Each motor will develop 10 horse-power at 400 revolutions per minute approximately. Single reduction gear is used; ratio of gearing $4.83 = 1$. The cars are fitted with a single motor equipment. The gauge of the lines is 3 feet 6 inches.

The Madras Electric Tramways Company is an English corporation. Its chairman, Mr. William Digby, C. I. E., is well known throughout India, in connection with a memorable piece of practical philanthropy. During the terrible Indian famine of 1877, Mr. Digby, who then lived in Madras, wrote a letter to the London "Times" appealing for help for the sufferers. Contributions to the famine fund that was forthwith organized poured in, and in four months $4,000,000 was subscribed. The distribution of this money, under Mr. Digby's superintendence, was made through voluntary committees, missionaries and others, at a cost of less than three-fourths of one per cent. In recognition of his labors, the British Government created Mr. Digby a companion of the Most Eminent Order of the Indian Empire. The Madras Electric road owes its inception almost entirely to Mr. Digby, who has thus in addition to his many public services, the credit of having promoted the first electric railroad in India. In London the interests of the company are watched over by Mr. A. C. Colebrook Codd.

On the directorate is Mr. M. M. Bhownaggree, a member of Parliament for Northeast Bethnal Green, and the only Indian Member of Parliament in the House. It will interest many Americans to know that one of the directors of the Company is Mr. W. A. Gibson, the managing director of the Otis Elevator Company in England.

The success of the Madras line is already stimulating a movement in favor of electric roads in other cities of India. Deputations have been sent from many places to inspect the working of the pioneer line. Negotiations are pending for the construction of an electric railway in Bangalore, and in both Calcutta and Bombay, the traction companies are understood to be about to operate the whole of their lines by electricity. In India, more even than in most other countries, does this



Steam Railway Crossing, Madras Electric Railway.

mean cheaper operating expenses, as well as better service. The abnormally high rate of mortality among draught horses, on account of the climate, can easily be realized by recalling the experience of the New York horse roads during the tropical spell of last August. The Bombay Tramway Company, which is an American enterprise, and which has been phenomenally successful, has the most elaborate arrangements for caring for its horses. They are all provided with topees, or sun hats, and when they come in from work they are sponged down with cold water, and put under a punkah to cool down gradually. A large number of the horses are imported from America, as an animal of special stamina is required for such exacting service. It has doubtless been already suggested to the Bombay Traction Company that American electric installations may not be a whit inferior in actual efficiency to American horses.

SOME RESULTS WITH ELECTRIC POWER ON THE B. & O.

BY T. FITZGERALD.

(Genl. Supt. B. & O. Railroad.)

It is with some little hesitancy that I write even a short sketch on a subject which has been so exhaustively dealt with from its several aspects; however, if public interest still remains active in following the results of this great enterprise and undertaking on the part of the B. & O. R. R., it is with pleasure that I review its growth.

It was in the pioneer days of electric lighting, that the B. & O. R. R. installed its first electric light plant for the purpose of furnishing, in a small way, arc lights at several of its points in Baltimore, as noted already in The Electrical Engineer. Since that time the railroad has found it advisable and to its interest, to take up the use of electricity both as a means of light, as well as motive power, probably more extensively than any other steam railway corporation, and the results have been both successful and gratifying.

The adaptibility of the various applications of electrical energy as viewed from the point of economy is shown by making a comparison of its equipment of but a few years ago, with that of the present, which has grown to the extent that this railroad is now operating thirteen plants, with two additional ones now under consideration, representing in all some 1,500 2,000 candle-power arc lights, 9,500 16 candle-power incandescent lights, and 3,300 horse-power in the shape of power.

Among this list of stations, one of recent and greatest interest, is the one located in Baltimore, commonly known as the "Belt Tunnel Plant," which has a rated capacity of 4,500 horse-power. Due to the difficulty and uncertainty of a ferry transfer, particularly in the winter time, on account of navigation being closed and the railroad being dependent upon this connecting link at Baltimore, coupled with the desire to lower the schedule time of its trains running between Washington, Baltimore, Philadelphia and New York, the question arose as to how this might best be accomplished. After careful consideration, it was finally decided to construct underneath the city of Baltimore, a suitable underground tunnel. At the instigation of this great undertaking, no definite plan had yet matured as to the exact manner in which trains should be operated through this tunnel.

In 1892, when the tunnel was nearing completion, it was found necessary at once to take up the question of determining quickly and definitely how these trains should be handled, because on account of the great length of this tunnel (which is about one and one-half miles) it was decided, from experience in this direction, that some different means of motive power than steam or some means of ventilation, would be required, not only as a matter of safety and convenience in operation, but considered from a point of comfort to passengers, and employés of the road.

After considering all points in favor of and against the several plans submitted for accomplishing the results desired, it was in May, 1892, that the contract was formally closed for installing a suitable electric plant together with specially constructed electric locomotives for the purpose of hauling freight and passenger trains through this tunnel. From the above date, progress in the way of perfecting plans and arrangements was rapid, and in May, 1893, ground was broken for the power house, which was to furnish power for the operation of these electric locomotives.

This work, together with the overhead construction, progressed uninterruptedly until its completion in June, 1894. On June 27, 1894, the first trial trip over the Belt Line with the electric locomotives was made. The entire length, including the tunnel proper and its approaches from either end, at that time, was about three miles. This trial trip was satisfactory, and on August 4, the electric locomotives went into regular service, and have been in use up to the present time, pulling all freight trains.

While those who had examined into the operation and pulling power of these electric locomotives, were confident of their ability to perform the work required, it was not until October of the same year that all doubts as to this were dispelled. It was on the fourth day of that month, due to some misunderstanding on the part of the operator, that two trains numbering in all forty-four loaded cars, together with three dead steam locomotives all coupled together, were stopped in the tunnel and started again by the electric locomotive, which did its work apparently as easily as with any ordinary train.

It was on a five-tenths grade that this performance was made, the total weight of the train being nearly 2,000 tons. The electric locomotive with this load, developed a speed of about eight miles per hour, exerting at times over an eight-tenths grade at the extreme end, a drawbar pull of about 62,000 pounds.

In the way of speed, with an ordinary passenger train, fifty miles per hour has been attained up this grade.

For some time after these locomotives were put in service, a great many railroad men, myself included, were skeptical as to the results they would ultimately produce, but from a practical standpoint, I am free to say that the electric locomotives operated by the Baltimore & Ohio Railroad on its Baltimore Belt Line, are without question, a perfect success.

This latter statement confirms itself by the fact that we are now making additional extensions, which when completed, will give a total length over which these electric locomotives will operate, of about four and one-half miles.

ELECTRIC TRACTION UNDER STEAM RAILWAY CONDITIONS.

BY JOHN C. HENRY.

Some ten years ago, the writer, in the columns of The Electrical Engineer, claimed the distinction of being the first to design and construct an electric locomotive that was used to haul standard gauge freight cars. Since that time the problem of "Electric Traction Under Steam Railway Conditions," which has been recently discussed by the American Institute of Electrical Engineers, has faced us. The record will show we have patented quite a lot of different forms of electric locomotives, the majority of which have been tested. My convictions as to what the most desirable mechanical and electrical constructions are, being so radically different from those proposed, I thought they might be of interest to some of the readers of The Electrical Engineer.

In the present state of the art, I am of the opinion that Mr. Baxter, Dr. Emery, or any one else who figures on the use of direct current machinery for long distance transmission, are wasting time. High potentials and the induction motor are here. Notwithstanding doubts to the contrary, the latter lends itself quite as well to regulation, if not better, than any direct current motor. By using a simple switch to change the number of poles of the field magnets, high efficiency is readily maintained under great changes of speed.

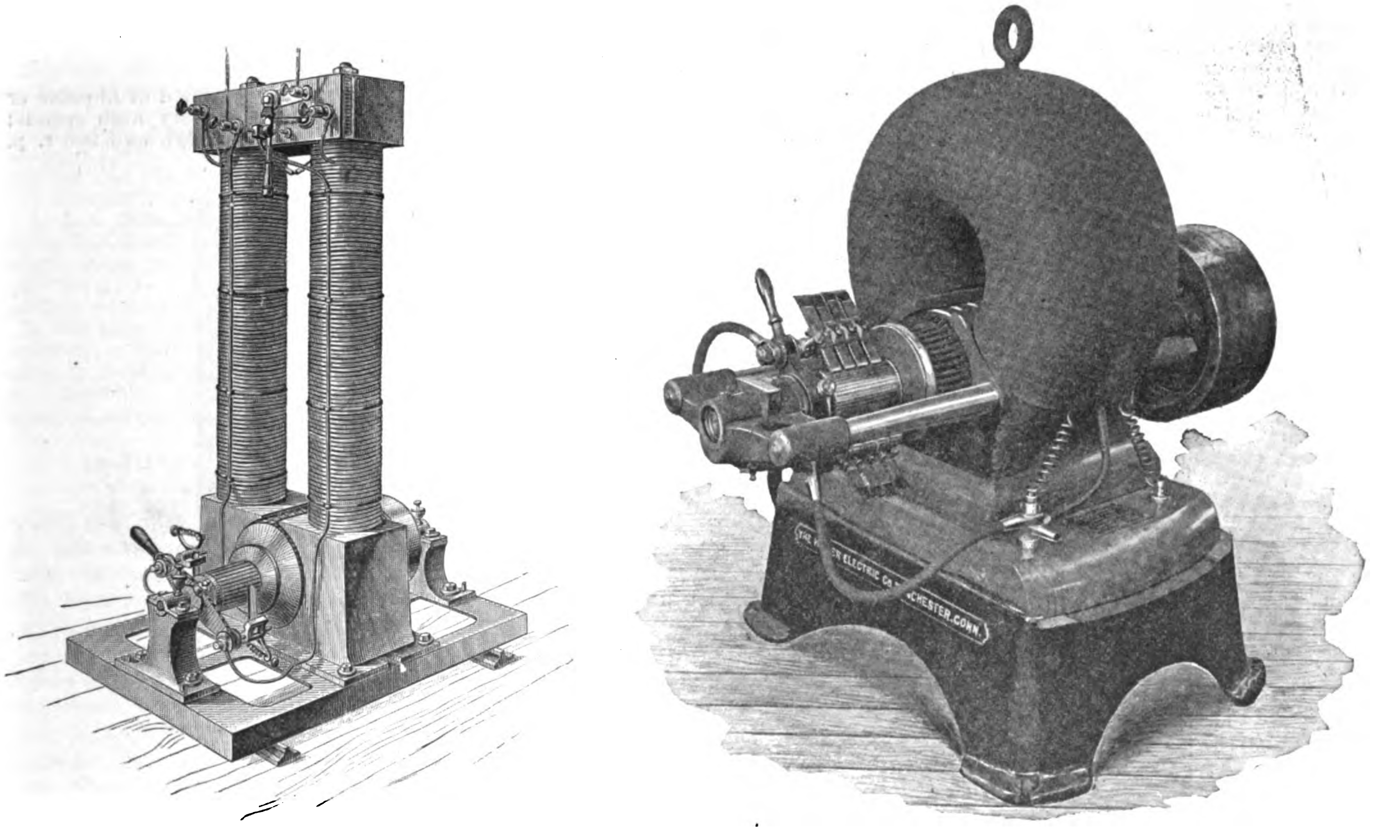
I disagree with Dr. Emery as to the desirable mechanical construction of the electric locomotive. He, I understand, proposes to follow the lines of the American steam locomotive, with all of its mechanical monstrosities, which have been necessitated by reciprocating movements and rough track. Although it is a wonderful piece of machinery and particularly suited to wiggle along over a rough and sinuous course, I think it would be a very difficult problem for a mechanical engineer to design anything (were it desired) as effective for the purpose of throwing the track out of line and knocking down the joints, as is the American locomotive, or even the ordinary electric car. To ensure that each wheel shall strike hard blows at every low joint, powerful springs are placed behind them. My judgment is—and it is based upon experience with both kinds—that where you have good track to start with, the axles may be supported in rigid frames as is the practice on English locomotives, and that they may be held in a position corresponding to what the track should be, so that when the latter is smooth all of the wheels roll on it; but where low joints, crossing, frogs, etc., are encountered, the wheels pass over without touching the depressions.

I appreciate the advantages of connecting rods, but they should be driven from the center and not from their ends, as is the common custom. In brief, I would propose to use a six-wheel rigid frame truck, with one pair of flangeless tyres, securing the armature of an induction motor to the center axle (either directly or through internal gear) and connecting the other axles thereto by rigid connecting rods, which link the three wheels together; such a construction having very few loose or wearing parts, could be constructed much cheaper than the common forms, and would be less liable to derangement.

I am aware of the stock objections that have been used against mounting railway motors on rigid supports. While they demanded attention in the early days before we learned how to make motors solid, they have but little force to-day. I think, were it desired to place electric motors within steam hammers, they would be forthcoming. With the passing of the brushes on dynamos and motor, we will be able to perform mechanical gymnastics that would make the direct current machinery dizzy. The old objections as to the evil effects of shock do not apply with much force to the best forms of induction motors. They have no commutators or brushes to be injured or disarranged. The armature on some of the best forms contains no wire, only a few heavy copper rods, which do not even require insulation. So that all that seems to be necessary is to cushion the field magnet wires, and this can readily be done by adding to their insulation.

In power plants, I think the present much admired, massive, cumbersome, direct connected dynamos are short lived standards, and that they must yield to the more scientific apparatus. That mechanical abortion, the sluggish acting centrifugal governor and the immense fly wheel, both of which have proved such elements of waste and destruction, are destined to the scrap heap. An electric governor which acts instantaneously is within the reach of any good electro-mechanical engineer. The dynamo of the future, whether needed for long distance transmission with converters, or for extensive city work and rotary transformers, will probably be of the induction type, the output of which can readily be doubled by substituting the field magnets for the fly wheel and driving it and the armature in opposite directions with a compound engine. This very desirable construction would be unobjectionable where the dynamos require no brushes, as is the case with inductors.

In conductors and trolleys there seems to be no occasion for improvements except to make the overhead work as trim appearing as possible. Such constructions as that at Baltimore are not liable to be duplicated. Whatever influenced the engineers there to use iron, with its low current conductivity, for conductors, and bridge work to support it, is a mystery to me.



OLD STYLE DYNAMOS.

The third rail, which was tried and abandoned by such celebrated engineers as Siemens, Edison, Field, Daft, Van Depoele and Fisher, appears to be again coming to the front. It, however, has too many objections to compete with the buried feeder and overhead span wire system, which I had the pleasure of introducing less than a dozen years ago. Although many hundreds of thousands of dollars have since been spent, and the genius of the world's best engineers has been devoted to schemes to avoid the overhead trolley wires, none of these so far developed are liable to be duplicated except under special conditions and in a very limited way. They are usually fascinating under favorable conditions, but lack the advantages of the high order of insulation that may be maintained with the exposed overhead wires. The flexibility and smoothness of the trolley's track, the exposed position enabling faults to be readily seen and easily repaired; these are almost essential features, and it is my opinion that any designer who ignores them will fail.

ELECTRIC LIGHTING

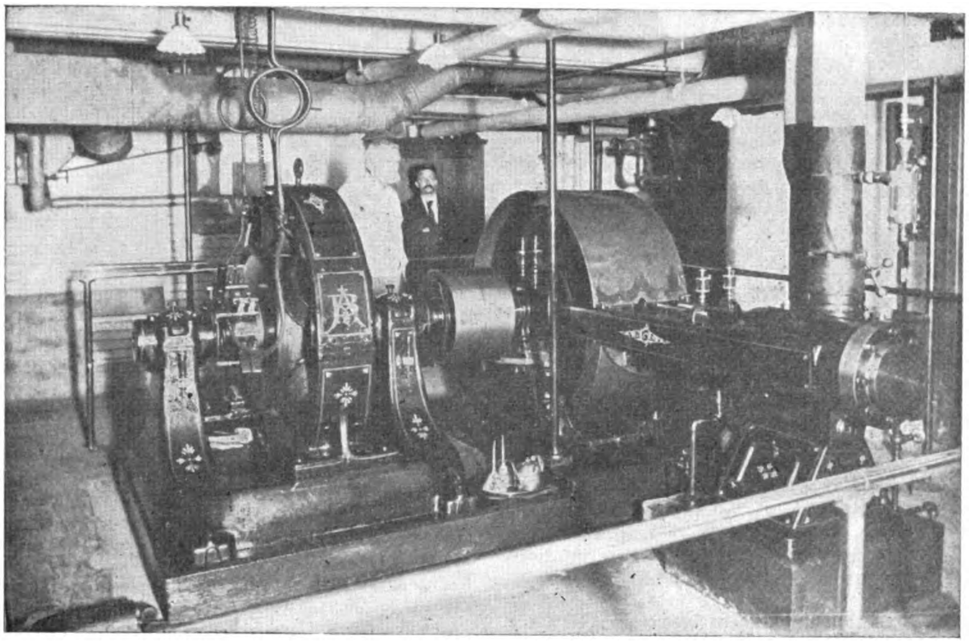
THE EVOLUTION OF THE ISOLATED ELECTRICAL PLANT DURING THE LAST FIFTEEN YEARS.—I.

BY CHARLES HENRY DAVIS, C. E.

IN the United States, the lighting of buildings by means of an electric current generated within the walls was in its infancy in the year 1880; the success or failure of an isolated electrical plant was a matter of conjecture; most of those installed up to that time have since been replaced, not only so far as generators are concerned, but also the wiring, fixtures, etc., in fact, in many cases, the entire system. Such plants when erected to-day are as certain of producing results desired as in any other branch of engineering; the evolution of this art in its various branches is of interest to history and as indicating the lines of development for the future.

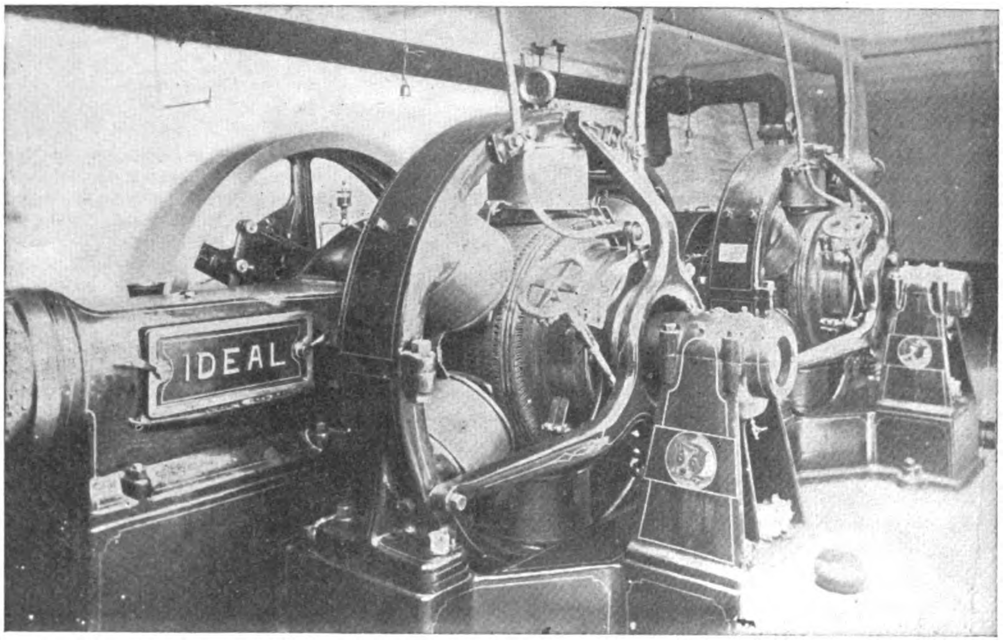
The first installations were designed for lighting purposes alone, while the modern plant operates lights, motors for elevators, fans and pumps, heating apparatus, arc lamps arranged for incandescent circuits, charging storage batteries,

etc., enabling the owner to utilize electricity in every part of the building and to dispense with hydraulic power and the use of gas where conditions show a saving. In the old days a plant involving the cost of ten or fifteen thousand dollars was considered large even with the then high cost of apparatus as compared with to-day, while now we have installations that exceed one hundred thousand dollars in cost; this, more than any one fact, presents most forcibly the enormous development of this branch of the electrical industry.



Modern Dynamo.

An isolated electrical plant is best defined as "a plant where current is not sold as the primary object of such installation," so that under this definition plants furnishing current for large works covering many acres would come within this class, although in their design and operation they approach the central station. In like manner private installations for mines or power must be included. While the broad definition seems necessary for the future, yet, now the term is more generally used as defining a plant located in the building which it serves; it is with the more general and present signification that the isolated electrical plant is treated of in this article. The term, isolated electrical plant, is usually shortened by omitting the word electrical, but strictly speaking isolated plant would include steam and electrical work; in making this distinction the writer will not consider the steam work of such installations. The subject will be divided into the following headings: Generating Plant; Switchboards; Wiring; Fixtures; Lamps; Motors; Contracts; Labor; Cost, and The Future.



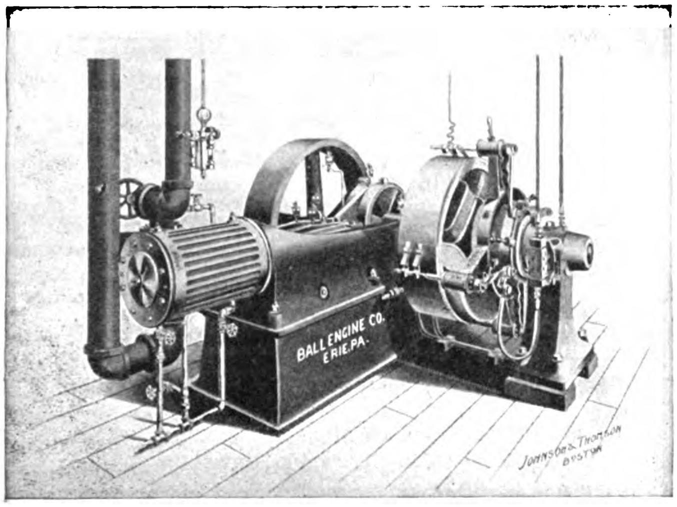
Modern Dynamo.

GENERATING PLANT.

The old time generating plant mostly consisted of bi-polar or consequent pole shunt wound dynamos of very high speeds; in some cases the speed developed was as high as 3,900 r. p. m. These machines had wooden bases, light shafts, small bearings with oil cups; were usually weak in mechanical design and sold at high ratings, causing hot and unsatisfactory operation; furthermore they were usually sold with the purchaser fully convinced that they needed "no attention" and were "automatic"; at first machines of different size were not run

in multiple. When compound wound generators were first put on the market the writer remembers the interest in the experiments and solution of operating them in multiple and the opposition to their use by manufacturers of shunt wound apparatus. The accompanying engravings show types used in the early days, in which is plainly shown the lightness of mechanical construction; these machines were not so inferior in their electrical efficiency compared to those of to-day as they were weak in their mechanical make-up and their inability to regulate closely made it impossible to maintain a constant potential at the lamps; compounding has become universal for the purpose of producing this result.

The development of better mechanical details led at once towards lower speeds to reduce wear and tear and this, combined with the necessity of saving space, has produced the slow speed, multi-polar, direct-connected generators of to-day, which are compounded, have bars of copper in place of wires on the armature, self-oiling bearings, steel castings, and laminated, toothed and ventilated armatures, gauze or carbon brushes and the best of mechanical design and workmanship. The illustrations show types made by several manufacturers of to-day. The belted machines run from 500 to 1,200 r. p. m., while the direct-connected are as low as 200 r. p. m. for the larger sizes, considerably below the older dynamos making 1,000 to 3,900 r. p. m. The improvement in commutation is marked, resulting in less sparking due to variations in load.



Modern Dynamo.

In the generating plant can be included the use of storage batteries, coming about the years 1884-85, and rapidly developing in their use only to lose the ground they gained by poor workmanship and unwarranted guaranties, but which are again an advancing factor in installations of this character.

15 YEARS' PROGRESS IN ARC LIGHTING.

BY PROF. ELIHU THOMSON.

THE past fifteen years is the period covering nearly all of the commercial development of arc lighting on the large scale. It is the period during which many great advances have been made and improvements introduced tending to the perfection of arc lighting technically and industrially.

At the close of the year 1881, there were but few central station enterprises based on electric supply, and practically all that enormous extension of such enterprises which has taken place began in 1881 by the establishment of a few stations for series arc lighting based mainly on the use of the Brush system. These stations were of very moderate capacity and sixteen to eighteen arc lights upon each circuit was considered a goodly number. The copper wire used for the line was entirely bare and generally without soldered joints. The writer well remembers that even in 1883 the lines in Cincinnati were of bare wire. It was there, in fact, that on the first production by the Brush Electric Company of machines of forty arc lights capacity, the foolhardy experiment of coupling up seven of these machines in series on bare copper was tried. But nature thus outraged rebelled and burned out several of the machines. This I think was in 1882.

Those were the days when an occasional Jablochkoff candle plant was to be found. But the electric candle soon burned out its life, though only burning at "one end." Those were the days of bad carbons; carbons bent like a bow, carbons soft, carbons hard, carbons from which the copper dripped when they were heated, or carbons which heated red hot throughout their length by their resistance. Those were the days of the "short arc" systems with twenty-five to thirty volts at the arc and twenty amperes for a (very) "nominal" 2,000 candle-power light. Those systems died; it was even evident then that they must eventually, and gave place to the "long-arc" or 40 to 50-volt arc, the true electric arc.

It was upon the use of the long arc that the Brush and Thomson-Houston systems were built and their commercial success and permanence was of course in a measure due to that fact. Curiously, we now see coming into vogue, extra long arcs, namely, the 80-volt enclosed arc on constant potential circuits, to which phase of arc lighting we will refer later on.

More might be said of the difficulties in the way of the first introduction of arc lights, but some of the obstacles which confronted the pioneer in the art have been alluded to above. In spite of the difficulties, the art grew and arc lighting became a recognized industry, while the economy and adaptability of the lights to streets and large spaces soon caused stations to be established in all the large cities and towns. The arc lights in use to-day in the United States are probably between one-quarter and one-half a milion. The color of the light of electric arcs was at first objected to as ghastly, but this prejudice, for it was only that, gradually wore away as the habit of seeing by the light became formed.

The design and appearance to the eye of the earlier lamps was certainly not pleasing, and in some of them decidedly the reverse of pleasing. For ungainliness there were examples which had not even the excuse of utility. Nowadays much more attention in response to demand is being given to the production of lamps of neat, convenient, ornamental design, and at times it would seem as if there might be danger of going to the other extreme, as when a man buys a watch for its case and gives little heed to the works. It should neither be necessary to "tight lace" the works and cut down the size of parts in an arc lamp to get it into a small case, nor should it be necessary to allow the "vitals" to spread out laterally to an inordinate degree so as to require what looks like a section of the largest size stovepipe to cover them.

The days of glycerine dash pots and glycerine carbon rods are past and gone. Such devices in clutch lamps were replaced by air dash pots and specially constructed, slow-feeding clutches. In geared lamps we still have those feeding by the removal of a detent from the feeding train and those working by an escapement oscillating from tooth to tooth. We still have series lamps in which the control is by a differential system of magnets, a winding in the main circuit acting magnetically to separate the carbons and opposed by a derived circuit around the arc. A great many lamps in use on series circuits are provided with derived circuit control only, as in the Thomson-Rice M & K lamps.

The improvements made in arc dynamos in late years have been such as are conducive to ease of handling and repairs. The capacity of the machines has, of course, been greatly increased during the past ten years. The regulation is now almost entirely some form of automatic brush moving mechanism, on the general plan of that introduced into the Thomson-Houston machines in 1880. It is sometimes combined with "field regulation," as in the later 125-light Brush machine. This plan of combined brush and field regulation was worked out by the writer with Mr. Rice about thirteen years ago.

A series arc dynamo is in some respects a peculiar machine. Dynamos to be used for running incandescent lamps may be very poor in design, but will work in a way. Not so with arc machines. Unless they have the proper form of characteristic curve they will give an unstable current, or a current which is only stable when largely in excess of that wanted for the circuit. In fact, the writer has found machines which were stable enough when working on differential lamps become unstable or "surge" badly when the load is of non-differential lamps, like the "M & K" lamps referred to above. The characteristic curve of the dynamo used for arc lighting must then be such as not only to imply a stability of current with arc lamps in series, but the curve may be required to be different with different lamps used as a load. For these reasons also arc dynamos cannot be designed to work with such high efficiencies as machines for constant potential work.

In regard to the running of arc light circuits, it is of course to be noted that a large amount of underground wire is now in use in cities and the result obtained while involving expense is in general satisfactory. Properly cared for, the cables maintain a high insulation and are of course out of the way of injury or leakage by crossing of other wires or by accidents due to storms. Naturally, it is a prime object to keep the potential between wire and earth as low as possible, especially when circuits of 75 to 150 lights are used.

In the recently constructed large Brush arc machines of 125 lights capacity, the full potential may be about 7,000 volts. But as the machine has three commutators and is therefore virtually three generators in series, a material saving of stress on insulation is obtained by connecting the lighting loops or circuits between the commutators in such a way that the circuits of light and generating armature coils in series alternate in position on the circuit. Thus the current leaving the positive brush of one commutator passes through a circuit of, say, 42 lamps, then in at the negative brush of the second commutator and out at its positive brush, through a second circuit of lamps, and so on, through the machine and lamp circuits in series. In such an arrangement the difference of potential between earth and line at any point is much below the total potential and in no case can it rise to be more than a moderate fraction of the whole. Within the past few years a certain amount of lighting has been done by alternating current arc lamps fed from secondary lines of alternating current plants. In some cases these lamps are a great convenience, but the lamps themselves are more sensitive to changes of voltage, require soft carbons, specially made for the work, and, for a given energy expended, the output in light is far below that of the direct current arc. The noise of the arc is also an objection except out of doors. The writer, in 1879, made attempts to enclose arc lights in globes so as to exclude the air. But it was found that owing to the great amount of impurities then existing in the carbons the glass was soon coated with a brownish deposit.

More recently similar attempts have been made from time to time and circuits of arc lamps have been run in series, each arc enclosed by a fairly gastight glass receptacle. It had long been known that if air was kept away from the carbons they would burn blunt or nearly square at the ends. This with ordinary lengths of arc would, of course, prevent the light from escaping except at angles not far from the horizontal plane. To overcome this the voltage and separation of carbons underwent an increase until now lamps are run at an arc voltage of eighty and a corresponding separation. An enclosed arc can naturally be an extra long arc without danger of being wafted aside by air currents.

Such lamps are now run with great success upon circuits of constant potential, such as the incandescent lamp circuits at 110 volts. With 30 volts taken up in dead resistance the arc at 80 volts has a sufficiently stable current. Lamps for three amperes, and particularly those for five amperes, are now standard.

Their chief merit is their long burning quality without frequent renewal of carbons. They can continue to be effective sources of light for 100 hours or even 150 hours with one set of carbons. While it is true that the actual light-giving power of such a lamp for a given amount of energy consumed at the arc is not as great as that of the naked arc, it is still, in view of the saving of carbons and attention, satisfactory.

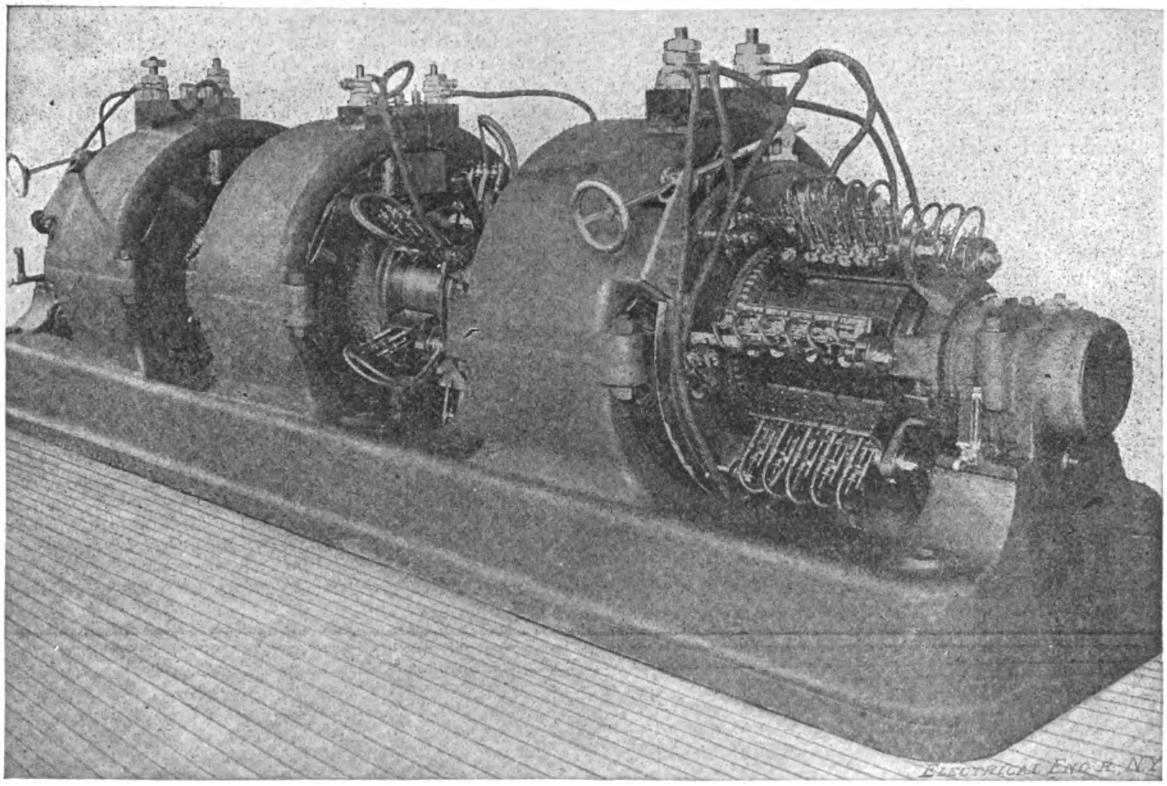
The success of such lamps depends upon purity of carbons and specially pure makes of them have to be used. Otherwise too great an obscuration of the sides of the globe will be the result. It is only in recent years that carbons fine enough for this use could be obtained. The "enclosed arc" undoubtedly fills a need, and its use will grow to considerable proportions in the near future. The lamps are even being used to replace groups of incandescent lamps in stores, etc.

In this brief reference to progress in arc lighting there is little more to say. It is to be hoped, however, that conditions may in the future be such as to permit the introduction of better means of hanging arc lamps in our streets. They do these things better abroad. Most of our arc lamp posts and hanging arrangements are as works of art described by the word "execrable." Let the cities furnish artistic, substantial poles and fixtures for the lamps and the electric station manager will take a pride in giving a light to match.

THE CHURCHWARD MULTIPOLAR BOOSTER.

THE Excelsior Electric Company has lately installed in the Second District station of the Brooklyn Edison Illuminating Company a booster of the latest Churchward multipolar type, for the Barstow booster system employed by that company. The machine is illustrated in the accompanying engraving.

The two end machines are dynamos having a capacity of 1,000 amperes at 50 volts. The middle machine is the motor, so constructed and connected as to run on either 125 or 250 volts; 250 volts when dynamos are required to give their current output at a high pressure and 125 volts when dynamos are required to give their current output at a low e. m. f. The advantage of this is that the dynamos will always have a comparatively strong field.



CHURCHWARD BOOSTER IN EDISON ELECTRIC ILLUMINATING CO.'S STATION, BROOKLYN, N. Y.

The dynamos are fitted with carbon brushes and the commutators are built up with drop forged bars, with sufficient surface so that the carbon brushes have bearing enough to carry the current at the low density of 20 amperes per square inch.

The advantages of carbon brushes for this type of machine are very evident. In cases where the load fluctuates severely as in motor service, or where the machine has to work on a constant current and variable pressure or again with constant pressure and variable current, if copper brushes were used they would require constant attention and adjustment, while with carbon brushes the severest changes of load can be taken care of without sparking and without adjustment of brushes. The machine illustrated was able to carry its full current at a pressure of 1 volt at full speed, showing that the armature reaction is very slight.

The fields of this type of booster are separately excited from the station bus bars. The rheostats are especially constructed with a great number of points, so that the voltage of the dynamo can be varied from 1 volt on open circuit up to 50 volts at 1,000 amperes.

The floor space occupied by this machine is 12 feet 2 inches by 34 inches wide by 37½ inches high; its weight is 14,153 lbs.

This is the second machine of the same capacity that Mr. Churchward has designed for the Edison Illuminating Company, of Brooklyn, the first one being in the First District station in Pearl street, and has been running a little over two years.

FIFTEEN YEARS IN CENTRAL STATION OPERATION.

BY SAMUEL INSULL.

(President Chicago Edison Co.)

As late as the winter of 1880-1 some of the best electrical experts of Europe, to say nothing of this country, were questioning the possibility of the success of the incandescent electric lighting system, the development of which is now universally conceded to Mr. Thomas A. Edison. At that time, a small distribution system was in operation at Menlo Park, N. J., and I well remember paying a visit there one evening immediately after my arrival in this country in March, 1881. I was naturally carried away by the enthusiasm of the moment, seeing for the first time an incandescent lighting system in operation. The pleasure of the occasion was greatly enhanced by having as my guide the illustrious inventor himself, and after spending the evening with him I hurried to the cable office to apprise my friends in London that Edison's electric lighting system was an accomplished fact.

Immediately after this Mr. Edison took up the engineering problem of designing and installing the first incandescent central station plant, so well known as the old Pearl street plant and system. I have often wondered whether Mr. Edison actually realized at the time the stupendous task before him. He had worked for several years in the laboratory, on his electric lighting system. Its success as a laboratory experiment was complete, but as a matter of fact in the year 1881, when he was probably more talked about than any other living American, his work had hardly begun. To launch successfully his great inventions in electric lighting, it was necessary not only to design the plant, the system of distribution, and the one hundred and one devices in connection with interior wiring, but also to equip one factory for the manufacture of incandescent lamps, another for the manufacture of generators, a third for the production of underground conductors, and yet a fourth for the construction of house wiring devices and fixtures. Whilst the money for the central station plant and distributing system was mainly provided by some of his banking friends, it should be remembered to his credit that Mr. Edison risked what money he had made as the result of his telegraphic and telephonic inventions, in equipping the four factories above refered to. Whilst he was loyally and ably assisted by a devoted corps of assistants, his was the master mind that carried through this great undertaking which was to a very large extent a leap in the dark; and when it is remembered that this first plant proved a great success and paid dividends on the original investment of $1,000,000, one cannot but admire Mr. Edison as an inventor and electrical engineer, to say nothing of his business sagacity which the success of this investment in an entirely new branch of industrial work demonstrated.

To one connected with the electric lighting industry at its inception, only fourteen years ago, it seems almost impossible to realize that in a decade and a half the business should have grown from nothing to such enormous proportions, as is shown by the fact that up to this time about $350,000,000 has been invested in 2,750 central station undertakings in the United States, and that probably $250,000,000 has, during the same period, been embarked in some 8,000 plants for isolated lighting.

The financial interest involved in so vast an investment is sufficient evidence of the absolute seriousness of the central station industry, but if this is not sufficient we have but to contrast the character of the construction adopted in connection with the large central station undertakings of to-day with the method of ten years ago. True, Edison's original scheme of direct connected units as shown by the "Jumbo" machines used in the Pearl street station has been revived, after the use for some years of belted generating apparatus, with the advantage that the great strides made in dynamo designing have rendered it possible to run at much lower speeds, enabling the central station manager to use vastly more economical steam generating machinery. Some writers make the mistake of assuming that because the early central stations were usually located in that portion of a city where real estate is generally the most expensive, the custom has become a necessity. Those engaged in the early exploiting of the central station industry are familiar with the fact that it was comparatively easy to induce the pioneer investors to expend a large amount of money on a valuable piece of real estate while it was a difficult task to induce the same people to make the outlay for a distribution system; hence the necessity for locating a station in the very heart of the business district—dispensing, as far as possible, with expensive feeders and foregoing the advantages of location near a railroad for cheap fuel or on the banks of a river or lake for condensing water—was made absolutely necessary by the demand for low initial investment.

To-day this situation has changed. The large modern stations with the most costly class of steam and electrical machinery in New York, Boston, Chicago and other large cities, are of themselves the best evidence of the confidence alike of the capitalist and the central station manager, and must be accepted as an answer to those writers who theorize as to whether central stations are doomed.

I know of several central stations in large cities which generate power, deliver it to the consumers, clear the business off the company's books, and, in short, pay all expenses excepting interest, at a cost not exceeding the cost of the gas companies in the same locality. If this can be done, surely it is only a question of obtaining the volume of business in order to produce relatively the same results as those obtained by the gas companies, as the investment necessary in both classes of business is not very far apart. It must be borne in mind, however, that the results referred to are obtained only through the agency of the most modern central station plants.

A central station manager is confronted with the necessity of finding some means of obtaining better results, so far as cost of generating is concerned, in the outlying territory, say, in the residential districts where the central station load is not heavy enough to justify the investment in expensive generating plant and where it is impossible to obtain the advantages of cheap water for condensing and adjacent railroad connections for cheap fuel. My experience has been confined mainly to the Edison low tension system, though I handle arc systems also, but it would seem to me that small central stations in outlying territory will be largely dispensed with in the next few years and their places taken by sub-stations, in which will be installed rotary transformers (and possibly a small storage battery equipment), operated by alternating feeders, the current for these being generated at the point where the main output of the company is produced under the most economical conditions.

This method has been decided on as the best one to be used in Chicago. Two small generating stations on the north and south sides will be abandoned within the next few years. All current will be generated from two large stations on the river where fuel can be delivered to the boiler room at the lowest possible price and water be obtained for condensing purposes at a trifling cost. The large low tension load required downtown will be generated by direct current generators, as at present, the load for the outlying territory being taken care of by means of generators of special design, and high pressure alternating transmission and low tension three-wire distribution from substations. By this means the same low cost possible in the district where great quantities of current are in constant demand will, except for the losses in transmission and conversion, be available as a basis for figuring the selling price in the outlying territory.

It is not the purpose of this article to go into the details of central station management and the possibilities of the central stations competing with isolated plants and with so-called block plants. The figures of cost to the central station plants given by some recent writers may have been correct, but if so, they simply bear evidence of the fact that the stations showing such results are ill equipped and poorly managed. The fault is not with the central station industry as a business, but with the design and management of the plant. On the other hand the figures given by the same writers as to the cost of operating isolated or block plants are theoretical and are not the results of practical experience. After operating both large and small plants from 10,000 horse-power down to a few hundred horse-power, I believe that the vast investment made in central station lighting is fully justified by the results, and the same principles properly followed out in every branch of industrial enterprise—showing that the wholesale manufacturer, although apparently having large expense, can compete with the small producer and occupy his field with profit—are equally applicable to the central station industry, as opposed to small producing enterprises such as block and isolated plants.

The success of the central station industry, however, does not depend alone on economical production. The judicious selling of his product is equally essential to the success of the central station manager. It often occurs that a customer who is willing to pay 20 cents per kilowatt hour for electric energy is not so desirable as one whose business can only be obtained at 5 or 6 cents per kilowatt hour. The central station manager who thinks that he cannot compete with an isolated plant where there are long hours of burning, assuming that he has a reasonably economical central station equipment, is usually led astray by a lack of knowledge of the elements that go to make up his cost of energy.

The more the central station manager elaborates the detail of his cost sheet, the more easy will it be for him to find means of competing for business, which will broaden his curve, lower his cost and increase the number of hours of each day that his plant is earning money for its owners. The selling price of 6 cents per kilowatt hour to large consumers having a steady load all day is no theoretical figure. It is a price very generally quoted. To my mind the obtaining of what might be termed the wholesale business, is a settled fact, and is much easier to deal with than in enlarging the business with small retail customers. The difficulty with the latter is in the way of wiring and fittings, few houses being at present equipped. But time will cure this, and with the tendency to centralization of plant, made possible by the great improvements in systems of distribution and the consequent low cost of production which will necessarily follow, it does seem to me quite within the realm of possibility that the small customers of central stations will within a few years, be able to purchase current at prices not much higher than those now charged in large cities for illuminating gas.

BROOKLYN, N. Y., has been talking municipal light plant, but she has already reached her debt limit, and not less than $2,000,000 would be required as a starter.

MECHANICAL

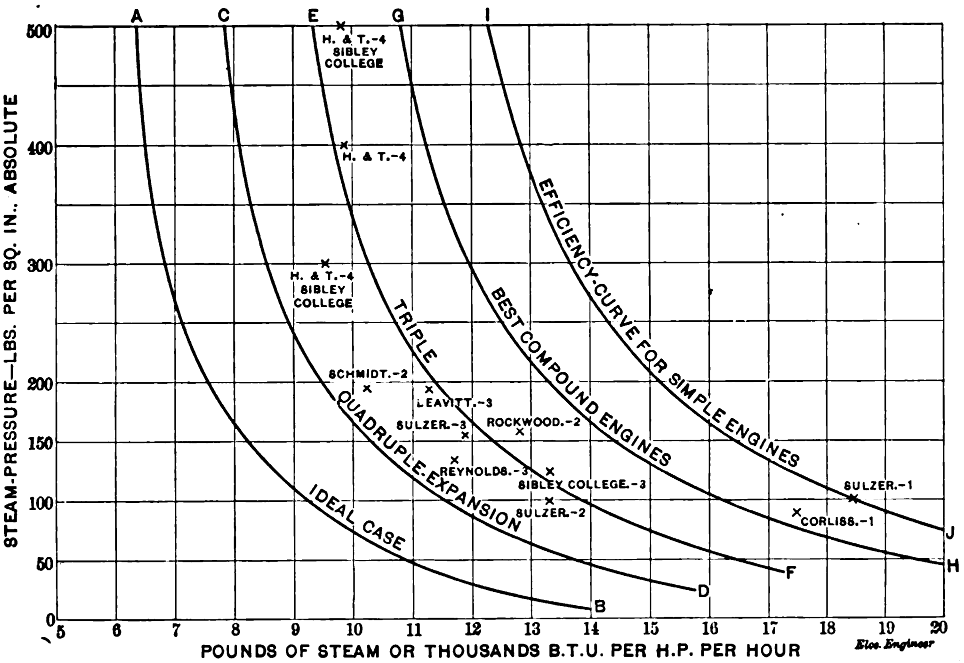
THE STEAM-ENGINEERING OF TO-DAY AND OF TO-MORROW.

BY PROF. R. H. THURSTON.

(Director Sibley College, Cornell University.)

IN the early days of electrical distribution of power and light, and, in fact, before the introduction of electric railways and of power distribution had fairly passed the experimental stage, the writer was asked by the editor of this journal to prepare a series of articles for publication on the subject of "The SteamEngine for Electric Lighting." These were published, later, by Messrs. Wiley, in book form, from plates kindly furnnshed the writer by the publishers of the original articles, and have now for many years been a reference book of the engineer and of the layman as well upon that subject[1].

In this series of papers was presented, as fully as space permitted, accounts of the then standard forms of the steam engine as adapted to the use stated, and a brief statement of the special and characteristic features of the machines described and of the design and construction of their principal details. As time went on and further progress was made, the book was revised, and, as happens, is now under revision once more, with the intention, on the part of publishers and author, of bringing it up to date by the introduction of the rather interesting and sometimes remarkable changes of later years.



EFFICIENCY CURVES OF BEST ENGINES, 1896.

At that date, the standard forms of engine in use for such work were the older Corliss type of engine, the Greene engine, the then still novel Porter-Allen engine, the earlier forms of "automatic," and all the beginnings of a now familiar practice. Since then, the drop cut-off engines have been improved by the addition of safety devices to meet the emergency of sudden loss of load or the slipping or breaking of the governor connections; their speeds have been increased from the old figure, forty-five to sixty, up to ninety and, in some cases, a hundred revolutions a minute, or more, bringing up their piston speeds to about six hundred feet a minute ordinarily. The steam pressures have risen from about eighty, as an average maximum, to one hundred and twenty-five pounds, in standard practice; while the consumption of fuel has dropped ten or fifteen per cent. Condensing is more common than formerly, and compounding and steam-jacketing are becoming familiar expedients for raising the efficiency of the machine.

---

[1] "Stationary Engines for Electric Lighting." By R. H. Thurston. New York: J. Wiley & Sons; 5th Ed., 1892. Reprinted with revision and additions descriptive of recent practice from "The Electrician," now "The Electrical Engineer." New edition in preparation.

"Automatics" have become formidable rivals of the engines with detachable valve-gear, in economy as well as through their special features of marvelously close governing, of a positive motion valve-gear, their consequently higher speed, and their special security against accident due to loss of load or injury to the governor and its connections. The contracted quarters often assigned this class of machinery, as a consequence of the often very high cost of real estate in the cities, has resulted in the introduction of the marine type of engine, with its vertical cylinders and peculiar forms of framing and accessory parts, and, under such conditions, the triple-expansion machine has often been found desirable.

At the boiler, the progress observed in increasing steam pressures, from the time of Watt, has continued, and, where economy of fuel is an important item, the water-tube boiler, built for 150 pounds and upward, is coming into use. In other fields of stationary engine and in marine practice, as in locomotive construction, 180 pounds is now not unusual and 200 and upward are figures beginning to be observed. There seems no reason why, as a matter of engineering construction, to-day, the now long familiar figures, of the practice of Messrs. Perkins, 350, 400 and 450 pounds, or more, even, should not be adopted. Mr. Leavitt has been long employing 185 pounds in stationary engine operation. Gain is observed with rising pressures, within the now actual range of maxima of leading practitioners, roughly speaking, as the square roots of the pressures—more accurately, probably, as the logarithms of the pressures. Superheating is employed to a very moderate extent in this country, and on rare occasions, while, in Europe it is now, as always, much more common and more radically used[2].

Where it is difficult to furnish ample floor space for the older type of boiler, the water-tube boilers are set, irrespective of relative costs; and when the head-room is ample and the ground area restricted, the vertical tubular boiler finds its peculiar place. Of the two classes, the water-tube and the fire-tube boiler, the former excels in capacity, as measured per square foot of heating surface; the latter is built and sold more cheaply. The one usually demands, for good work, about ten square feet of heating surface per conventional horse-power—34½ pounds of water evaporated "from and at" 212 degs.—and the latter requires twelve to fifteen; the last-named figure being that adopted by the older and more experienced builders. Isherwood's experiments, a generation ago, showed an advantage in capacity and in economy, other things equal, on the side of the former, of about 10 per cent., and later practice confirms his deduction. Either kind of boiler, set, and in operation at its rated power, should be capable of delivering, when forced, at least one-third more power, for use in case of emergency. Some boilers may be forced to double their rating, especially with the soft coals. The best designers give excess of about forty or fifty per cent. to meet such cases.

The unanticipated reduced cost of recent years in the production of the compound engine, and its large gain, as compared with the simple machine, giving at once an engine of moderate cost, and of greatly reduced magnitude and cost of the boiler supplying it with steam, has now, in many, if not in most cases, made the first cost of the plant less than that of the simple engine and its boiler, so that we have, in such instances, the curious fact observed that both first cost and economy of operation dictate the use of the compound engine. As a rule, also, as shown long ago by Mr. Emery, the compound is the most desirable form of engine, on the score of total running costs, whether compared with the less economical simple engine on the one side or with the more efficient triple and quadruple expansion engines on the other side. The latter, nevertheless, where exceptional economy is rendered essential by high price of fuel and of boilers, find their place and may pay handsomely.

In detail, the engine of to-day excels in its admirable proportions of running parts, in the solidity and symmetry of its frame, and in the extraordinary efficiency of its governing mechanism and of its valve-gear and steam-distribution[3]. That now well-recognized aid to improved efficiency of thermodynamic action of the machine, the steam jacket, is more generally used in this country than formerly, though not nearly as generally as in Europe, except on steam pumping engines and other slow-moving machines. Its value is coming to be well-established, and at its true rating, however, and the conditions under which it may be safely and economically employed are now well understood by intelligent and well-informed engineers engaged in steam-engine design and construction[4].

The steam engine of to-day has, through the intelligent application of the now familiar principles and methods of modern construction, assumed a fairly standard and probably nearly permanent form and proportion, and the anticipated improvement of the coming years seems likely to be the result of gradual increase in the pressure of steam employed and of the introduction of more and more superheating. The best usual figures for our practice of to-day, may be taken as substantially as follows, for saturated steam at 125 pounds and for large jacketed condensing engines:

Simple "drop cut-off" engines, lbs. steam per I. H. P., per hr.	20
Compound engines, lbs. per I. H. P., per hour	16
Triple-expansion engines, lbs. per I. H. P., per hour	14

Two pounds less may be reached under especially advantageous conditions, and superheating may still further add to economy ten per cent. and upward. The unjacketed engine should be expected to consume at least ten per cent. more steam than the above, and throwing out the condenser may reduce the economy something like twenty per cent. in ordinary and representative average cases. Gains and losses are, however, in actual practice, very variable and depend greatly, for their magnitude, upon every variable condition of design, construction and operation.

The outlook, in respect to engine efficiency and economy in the use of heat, steam and fuel, may perhaps be fairly well indicated by the data exhibited in the accompanying diagram, which represents the variation of efficiency and economy in the expenditure of heat, steam and fuel, in the ideal, purely thermodynamic, case, under the most favorable conditions of actual practice, as seen on the curve A B; in the case of an engine in which the total of all wastes is taken at about one-fourth the supply, as on the line C D; and in cases in which larger proportions of heat fail of useful thermodynamic transformation, as on lines E F, G H, and I J. Condensation and a good vacuum are assumed, and a feed-water supply at such a temperature as will store about one thousand heat-units in each pound of steam passing through the engine and boiler cycle, where jacket-water is included.

The forms of these curves are substantially exact, their location being representative of good practice, and the area bounded by them being taken as inclusive of the whole field of best recent practice. The limiting curves are those for good modern practice with the simple engine and the case of the perfect thermodynamic machine; while the intermediate curves may be taken as approximately illustrating past and prospective experience with the multiple-cylinder engines. The data obtained from recent records are illustrated by the points inscribed in this field, the number of cylinders in series, in each representative case, being indicated by the attached figure.

It is seen that the best simple engines recorded are the Sulzer, which gives a point on the curve I J, and the Corliss, a simple engine which excels the former somewhat and gives a point nearly attaining the first line, within the curve G H. The best compounds are the Rockwell, which nearly reach over to the line assigned good triple-expansion engines, and the Sulzer which excels that standard and approximates that of the triple-expansion engines of contemporary practice. The best triple-expansion engine results, judged from this standpoint, are those of the small experimental triple expansion of Sibley College, designed by Reynolds, working at 113 horse-power, and which comes close up to the standard curve assigned this class, the Leavitt and the Sulzer, which approximate the standard but somewhat excel it, and the Allis, another design by Reynolds, which considerably excels the standard. The Schmidt engine is a small compound machine, brought over into this part of the field by its effective system of superheating.

The only quadruple-expansion engine in the set is that of Hall and Treat, built as an experimental engine and the property of Sibley College. This falls into one or another of our standard curves accordingly as its system of drying and reheating steam is made more or less effective. Were either of the experimental engines here referred to reproduced on the scale of the larger engines with which they are here brought into comparison, the resultant diminution of internal heat-wastes would carry them over near the standard line next the ideal, and they would then demand less steam, heat and fuel by presumably twenty-five per cent. at least. The line adjacent to the ideal, here marked quadruple-expansion, is that which experience seems, in the judgment of the writer, to indicate may be hoped and fairly anticipated to become that of best actual practice when the design, the construction and the operation of the engine is made in all respects as satisfactory as present knowledge and our improving skill should permit.

[4] "Authorities on the Steam-Jacket; Theory of the Steam-Jacket." Trans. A. S. M. E. By R. H. Thurston. 1890; Vol. XII.; 1894, Vol. XV. Nos. CCCCXXXV., DLXXXIII.

The general trend of the curves indicates the gain to be anticipated from increasing pressures when we shall have become as competent to avail ourselves of them as we are today in the use of the familiar pressures of our own time. The thermodynamic value of either engine is obviously measured by its economy in the use of steam and, especially, by its approximation to the ideal curve. The line C D is the estimated position of the quadruple-expansion engine of Sibley College, reproduced on the scale of the large engines with which it comes into competition on the diagram. In the comparison of types and of performances of engines, it is now clearly seen that the simple statement of their relative demand for steam or for heat is not a true gauge; the figure must be compared with the curve of efficiencies in the manner here illustrated to determine the real position of the engine, thermodynamically, and the merit of the design.

The success of the steam-engine designer and constructor is not, however, entirely dependent upon his own efforts, or even upon the intrinsic merit of the machine, or on the location of its representative datum upon our diagram; it depends, in very large and often controlling degree, upon the conditions of the case outside the engine room. It is only when the load upon the engine is held constant, and at that amount for which the machine is best proportioned that the maximum efficiency of the engine can be secured. Every variation from its best load, and especially in the direction of reduced demand for power, causes loss of economy of power-supply. The disposition of the plant in such manner as to insure the most uniform possible load upon the engine, and the assignment to each machine of its proper proportion, securing so far as practicable its best load, is a primary requisite of economical operation. In the design of large stations this problem is less difficult of solution than with smaller loads; but it is usually the principal obstacle to the attainment of highest duty. As the storage battery becomes more satisfactory in first cost, in endurance, and in operating expense, this problem will become less and less difficult of solution and the perfection of a steam power system in the distribution of electrical energy will come, when this or some other method of giving the engine its best and a constant load can be secured.

THERMO ELECTRICITY

ELECTRICITY FROM COAL, WITH AND WITHOUT HEAT.

BY WILLARD E. CASE.

All great discoveries necessarily pass through a process of evolution. Since the discovery of the arc by Davy and its more successful operation through the demonstrations of Faraday, the science of electricity has made great strides. The century's advance has been so rapid that no one dares predict what is possible. The feeling has existed for several years that an immense amount of energy is being wasted in generating electrical energy by steam. It is an inexorable law of nature that under the conditions in which we live, a great waste must accompany the transformation of heat into any other form of energy. To condense steam in the condensing engine it requires four or five pounds of water to every pound of steam. Three-fourths the heat used goes to warm the water and is wasted. In hot air engines, or gas engines, a cold water jacket must be used and to it goes the larger share of the heat employed. In the thermopile one set of junctions must be kept cool by circulation of air or water. In Edison's pyromagnetic generator the iron tubes must be cooled by a blast of cold air.

By the second law of thermo-dynamics the minimum amount of heat that goes to this cooling agent is the fraction, $\frac{t}{T}$ of the total amount employed, where t is the temperature of the cooler reckoned from the absolute zero, and T the higher temperature of the working substance; t cannot be less than 500 degs. so the numerator of the fraction is always large and the heat wasted is the larger portion. Let it be understood that this is a law of nature, it is inevitable under the conditions in which we live. No cunningly devised furnace, or feed water heater, or cut-off, or triple expansion apparatus, or pyrogenerator can save this heat. The most that any of these devices can do is to save what would otherwise be wasted over and above the proportion $\frac{t}{T}$.

But are we to go on wasting all this energy of fuel? Cannot some means be employed to utilize it? We know that the voltaic battery is not a case of the transformation of heat into electrical energy, it produces electrical energy directly. The second law of thermo-dynamics does not apply, as no heat appears. If we could convert the chemical energy of coal and oxygen into electric energy direct, and cheaply, we would do away with our steam motors in time. There is no known reason why a cheap substance may not be found which will act on coal and develop electric currents in place of heat. This electric energy would be the equivalent of the heat energy that would be developed by the combustion of the same coal in the ordinary way, and could be transferred into mechanical power, heat, light, etc., with small loss.

In a paper read by the author in 1888 before the American Institute of Electrical Engineers, this principle was advanced, and a carbon consuming battery shown which operated in the cold, demonstrating its success theoretically, but not commercially, as the oxidizing agent was too expensive. The cell consisted of platinum opposed to carbon in an electrolyte of water saturated with chlorine peroxide. The carbon was attacked and oxidized to carbonic acid, as proved by analysis. The e. m. f. equals over one volt.

A résumé of some of the efforts to solve this problem, which have fallen under the author's notice, put in chronological order, may be of interest. They may be grouped as follows: 1. Cells which were devised to utilize the oxygen of the air. 2. Carbon consuming cells. 3. Cells combining both principles. And it is surprising to find they were all co-existent some years ago.

1. Of the cells which develop electricity by atmospheric-oxidation Gladstone and Tribe[1] in 1873 described a cell which consisted of a tray full of silver crystals as one electrode, opposed to a copper plate immersed in a solution of 6 per cent. copper nitrate; cuprous oxide is formed and deposited on the silver; the oxygen of the air being the active oxidizer; e. m. f. about $^1/_{10}$ volt. They also described in the same paper a cell formed by opposing zinc to copper in a 20 per cent. solution of zinc chloride. Oxygen of the air is absorbed, giving an e. m. f. of $^7/_{10}$ volt. In 1887 Wright and Thompson[2] showed a cell in which copper is opposed to platinum in a solution of ammonia; oxygen of the air is absorbed and cupric oxide formed which goes into solution, e. m. f. equals $^8/_{10}$ volt.

Andreas[3] also described another form which comes in this class, as oxygen of the air plays a part; he uses two carbon tubes immersed in dilute sulphuric acid, and supplied respectively with sulphur dioxide and chlorine under pressure; e. m. f. $^5/_{10}$ volt. The products of the action are sulphuric acid and hydrochloric acid.

2. Cells in which carbon is oxidized to produce electrical energy. Jablochkoff's "heat cell" brought out in 1877, consists of a vessel, the positive electrode of cast iron, containing a fused bath of nitrate of soda which supplies the oxygen that attacks the negative carbon electrode; e. m. f. equals one volt.

Bard "Brick," so called, was brought out in 1882. The electrodes, tablets of carbon and nitrate of potash, were separated by sheets of asbestos. When placed in the fire it gave about one volt.

About the same time we had the Crum heat cell. This consists of carbon, iron, black oxide of iron fused. in which the carbon is attacked. Also Edison's carbon consuming cell in which a fused oxide is reduced by carbon. the bath being regenerated by oxidation.

Andreas' cell[4] consists of two carbon electrodes separated by a porous partition, the one immersed in a solution of cuprous chloride, the other in one of cupric chloride; carbon monoxide was led into the first compartment and chlorine into the other, the combination gave 10 ampere hours with an e. m. f. of $^6/_{10}$ volt.

Dr. Bucherer[5] has described this form of cell, in which he attempts to oxidize carbon monoxide. The apparatus consists of a wrought iron vessel containing a fused bath of potassium and sodium carbonate; the electrodes are hollow, supplied with carbon monoxide and oxygen under pressure.

3. Cells combining both principles in which the oxygen of the air is made to attack the carbon:

(a) Without the aid of external heat. Wright and Thompson[6] in 1889 described an attempt to produce a current by oxidizing coal gas or hydrogen with the oxygen of the air, in a solution of alkaline permanganate; or sulphuric acid, and potassium dichromate. Many other cells of this class have been described by others, but no great advance seems to have been made.

[5] "Electrician" (London) Nov. 29, 1896.
[6] Proc. Roy. Soc. 44, 182-200.

(b) With the aid of external heat. The first cell of this class, which came under the author's notice, was during the discussion of his paper above referred to, on "Electric Energy from Carbon Without Heat," in 1888, when Mr. C. S. Bradley[7] described experiments he had performed in 1882 with fused salts and their action on coal. He said oxygen of the air is absolutely necessary. His cell as described "consisted of of fused sodium manganate, and putting a blast of air through it, and by that means supplying it with oxygen and allowing it to act on the coal, which is put in another part of the vessel. A little over one volt was obtained."

A cell described by W. W. Jacques in Harper's "New Monthly Magazine," for December, 1896, is another illustration of this same principle with a few practical modifications. It is said to produce electric energy at a very economical rate and to consist of an iron vessel which is the negative electrode containing the fused salt, caustic soda, into which is plunged the positive coal or carbon. Oxygen is supplied by putting a blast of air through the fused bath. An e. m. f. of about one volt is obtained.

The electrolyte conveying the oxygen of the air can be heated as Bradley, Jacques and others do without infringing the second law of thermodynamics, as the law does not apply so long as the oxydation of the carbon itself does not produce heat, but electricity. There is heat in all electrolytes down to absolute zero. The electrolyte is simply heated to permit the chemical affinities to act. Of course this heat is wasted if it is above he normal temperature under which we live, unless it is a reaction which absorbs heat.

MARRIED

HOPKINS-DORSEY.

The marriage is announced of Mr. Nevil Monroe Hopkins to Miss Katherine Guy, niece of Miss Anna J. Dorsey. Mr. Hopkins is well known in electrical circles. He was at one time connected with the General Electric Company, and is now practicing as an electrical engineer in Baltimore and Washington, representing also The Electrical Engineer, which begs to tender its congratulations to the happy pair.

OBITUARY

WALTER B. CHILDS.

Mr. Walter B. Childs, a young electrical engineer, died on December 21 from pneumonia, at the Homeopathic Hospital, Pittsburg. He was 29 years of age. He was employed by the Electric Construction and Supply Company.

JOHN OWEN RICHARDSON.

The death is announced of John Owen Richardson, superintendent of the Wissahickon Electric Light Company's plant, Philadelphia. Mr. Richardson was born in that city, November 25, 1851, and after acquiring an education, learned mechanical engineering. He subsequently removed to the South, where he had charge, as chief engineer, of a number of steamboats that ran from Tampa, Fla., along the gulf and Atlantic coasts. After his return to Philadelphia he had charge of the Lincoln Park boats on the Delaware. Mr. Richardson died of heart disease, after a week's illness.

EMIL DU BOIS-REYMOND.

Prof. Emil Du Bois-Reymond, the distinguished physiologist, died in Berlin on December 26. He was born in Berlin in 1818. He began studying theology, but abandoned this for natural science. After a sojourn at Bonn he returned to Berlin, and studied anatomy and physiology under Jean Muller, and on his advice undertook his researches in animal electricity, on which subject he published several works. In 1868 he replaced his master as professor of physiology at the University of Berlin, and was named, in 1867, perpetual Secretary of the Berlin Academy of Sciences.

ROENTGEN RAYS

FLUORESCING SALTS.

BY THOMAS A. EDISON.

FURTHER experiments, beyond those already recorded by me in The Electrical Engineer, have been made with crystals sensitive to the X-ray of Röntgen. The following are selected from a large number of chemicals made at my laboratory, all the chemicals in commerce having already been tested and reported: Borate of Sodium and Uranium; Cyanide of Copper and Zinc; Cyanide of Copper and Silver; Cyanide of Silver and Calcium; Cyanide of Silver and Tin; Cyanide of Silver and Strontium; Cyanide of Silver and Barium; Cyanide of Copper and Lithium; Phosphate of Uranium and Ammonium; Phosphate of Uranium and Silver; Nitrate of Uranium and Lead; Cyanide of Uranium and Silver; Nitrate of Uranium and Strontium; Nitrate of Uranium and Potassium; Benzoate of Uranium and Copper; Benzoate of Uranium and Cadmium; Dicalcium Tungstoborate; Dimanganeese Tungstoborate; Cyanide of Mercury and Chromic Chloride; Cyanide of Mercury and Fluoride of Calcium; Cyanide of Cadmium and Silver Phosphate of Uranium and Calcium; Phosphate of Uranium and Zinc; Phosphate of Uranium and Sodium; Phosphate of Uranium and Magnesium; Phosphate of Uranium and Aluminum Phosphate of Uranium and Beryllium; Phosphate of Uranium and Manganese; Cuproso Potassic Cyanide; Cyanide of Iron and Barium; Cyanide of Cerium and Copper; Cyanide of Copper and Molybdenun; Cyanide of Copper and Barium; Cyanide of Copper and Iron; Cyanide of Copper and Zinc; Cyanide of Cerium and Silver; Cyanide of Copper and Cadmium; Cyanide of Copper and Manganese Cyanide of Cobalt and Copper; Nitrate of Uranium and Silver Nitrate of Uranium and Lithium; Nitrate of Uranium and Barium; Acetate of Uranium and Copper; Acetate of Uranium and Silver.

WHY FRANKLIN STILL LIVES.

There are, I conceive, two chief reasons why the name of Franklin is so constantly on our lips and his memory so impressed upon our hearts—why, in other words, he really lives for us instead of being a mere fossil in the strata of history. One is that as an embodiment of practical learning, shrewd mother wit, honesty, and patriotism he is a typical and in many respects unapproachable product of true Americanism. The other is that he is the most complete representative of his century that any nation can point to. With regard to the typical character of his Americanism few cavils will be raised, but with regard to the claim that he best represents the eighteenth century there will probably be not a little dissension. Washington, Dr. Johnson, Frederick the Great, and Voltaire might each and all be put in competition with the sage who snatched the lightning from heaven and the scepter from tyrants, and would have many supporters. But in none of these does the age of prose and reason seem to find such an adequate and complete expression as in Franklin. Washington is beyond his own or any century; Dr. Johnson does not sufficiently represent the age on its rational side; Frederick is too extreme a combination of daring and sublime seriousness of purpose and petty affectation; while Voltaire is at once too intense and not radical enough, and is, after all, too entirely a man of letters. Franklin, on the other hand, thoroughly represents his age in its practicality, in its devotion to science, in its intellectual curiosity, in its humanitarianism, in its lack of spirituality, in its calm self-content—in short, in its exaltation of prose and reason over poetry and faith.—Professor W. P. Trent in "McClure's Magazine" for January.

Vol. XXIII. NEW YORK, JANUARY 6, 1897. No. 453.

FIFTEEN YEARS' ASPECT OF TECHNICAL JOURNALISM.

BY C. J. H. WOODBURY.

(*First Editor of The Electrical Engineer.*)

AMONG the few books that I am sometimes pleased to call my library, there are none which have a greater attraction to me than the bound volumes of The Electrical Engineer, comprising the entire series, beginning with the first issue of the modest publication preceding the title of the present paper. An important feature of interest of this remarkable series of volumes showing the world's progress in electricity and allied subjects during the fifteen years, has been the advance in technical journalism. Well might a person remark in comparing one of these earlier monthly numbers with the present weekly issues, "Look here upon this picture and on this." Although a review of this continuous record of years agone naturally turns one's thoughts to the retrospective, yet the true concentration of interest should be on the affairs of to-day, looking to the past only for the definite purpose of its application to the present time.

The technical paper of to-day, might well bear as a motto the oft-quoted inscription to the memory of Sir Christopher Wren, the architect of St. Paul's, over one of the doors of that edifice, "If you seek a monument, look around." The enlarged scope and importance of the electrical technical journals, is only proportionate to the greater extent of the interests to which they are devoted. This is fundamentally due to the increase of capital invested in the electrical industries. With this growth, has developed a market both for subscribers and advertisers. It is here as in all fields of life, that the occasion has developed men suited to the work; the editorial pages have changed from the extremes of the work of men who were either solely writers or solely physicists, to those who blend together the trained ability of both extreme types; journalists have become electricians, and electricians journalists. The logic of figures to prove the extent of this great advance in technical journalism might best be obtained from the publisher's books which would give a statement showing the increase in circulation, advertising accounts, as well as the added number of columns and the improvements in typography graced by finer illustrations, but these remain for the reader only to give his impression of a greater usefulness in the development resulting from such work.

An important element of the progress in technical journalism is due to the wider application of photography; not only in the half-tone engravings, but also in the general use of the camera, enabling those interested in the constructive branches of electrical engineering, to illustrate their work with photographs, which are reproduced identically.

The greater diversity of electrical interests has rendered the technical press more independent; there is less editing by advertisers and therefore the well considered criticisms of technical papers are becoming more valuable. The applications of electricity are so far beyond the acquirements of any one individual even a specialist, and its rate of progress has been so rapid, as to outstrip the publication of books, so that technical journals have become a part of the reference libraries, of those engaged in any element of electrical work. The electrical journals offer a weekly encyclopædia, bringing individuals in touch with the progress, chronicling the advance of the art which enlists the resources of the capitalists in co-operation with the investigations of the electrician in a work whose application extends to the welfare of all.

A VOTE OF CONFIDENCE.

IF there is one thing more distasteful than any other to The Electrical Engineer, it is to talk about itself, praise its own efforts or success, and try by disparagement to crowd its contemporaries off the face of the earth. The readers of this journal have to endure some shortcomings in it, but as much as possible they are spared the waste of space on effusive self-glorification. The present issue of The Electrical Engineer, marking its fifteenth anniversary and the beginning of its sixteenth year offers an unusual temptation to depart from wonted reticence, but no more will be made of it than to say that, after the term of existence marked by the earnest and brilliant efforts of others before the present management of the paper, the special technical contributions to its columns and the magnificent patronage in its advertising pages, are accepted as a vote of confidence, which in turn pledges to even higher aim and better work in the future.

The first issue of the Engineer in January, 1882, when absolutely no other American electrical journal had been started, and when it proposed only a modest monthly appearance, contained 16 pages all told. The present number contains at least eight times as many, the pages being now of the same size as then. During its career, the Engineer has seen vigorous weekly electrical journals spring into being, but having itself become a weekly in 1890, it has now for six years past more than recovered the ground lost as a monthly, and measures up with its friends on even terms of equality. Indeed, it is possible that The Engineer as the oldest electrical journal is shown by this issue to be also in other respects at the head; but a paper is certainly not judged on its own valuation and mere figures of bulk or circulation are not the safest indications always of true merit.

The publication of a programme of what The Electrical Engineer will do hereafter is not easier than it would be to define the actual development of electricity in the coming years. It can only be said that in the growth of the great electrical arts lies the fullest incentive that any journal could ask, to the best and most conscientious performance of its duty. To assist in this unfolding is itself a reward; and as the field enlarges the opportunities for all will multiply.

We cannot let this issue go to press without extending our thanks publicly to the contributors, men on whose position in the electrical field there is no necessity to enlarge, who have by their admirable articles, made its contents so unusually interesting and valuable. Their kindness to us and our readers on this occasion is deeply appreciated.

THE INCANDESCENT LAMP—PAST AND FUTURE.

A SURVEY of the past fifteen years would be incomplete without mention of the incandescent lamp, the changes it has undergone and the effect it has had on the industry at large. So far as the changes are concerned, it stands to the enduring credit of Mr. Edison that not only the main principles, the materials of its construction, but its very form have remained practically the same as he left them when he announced his system of incandescent lighting as commercially practicable. Of course, we do not ignore the many details which have been introduced looking to cheapening of the process of manufacture which have indeed had a marked influence on the commercial side of the incandescent lighting industry. Nor can it be denied that the efficiency of the incandescent lamp has been vastly increased since it was first brought out. In the early days, six or eight lamps to the horse power was the usual guarantee, whereas fifteen is now the standard practice. This means a lamp giving one candle-power for 3.1 watts consumed. One cannot look upon the past without a conviction amounting almost to a certainty that still further improvement will and must be made in incandescent lamp efficiency and that the twenty-to-the-horse-power lamp will before very long make its appearance. There has long existed a struggle among central station operators to strike the correct mean between the life and the efficiency of lamps; in the one case to reduce the cost of renewals, in the latter to reduce the coal bills. It is true that the recent enormous reduction in the first cost of incandescent lamps has changed considerably the aspect of the case, but other considerations, of not less weight, make the striving for the twenty-to-the-horse-power lamp as desirable as it was at any time in the history of the art. Twenty lamps to the horse-power means operating them at less than 2½ watts to the candle-power, so that the "standard" would be a 37½ watt lamp. Such a lamp would at once reduce the station coal bill 25 per cent., and would involve reductions of expense in other directions. Or, looked at in another way, it would increase the station capacity by a like fraction, thus converting, say, a 10,000 light station into one of 12,500 light capacity, without any increase in running expenses. With the fixed charges and expenses remaining practically unchanged, as they would, such a station would be able to increase its income nearly 25 per cent., and this, in many cases, would mean an increase in net profits of probably 50 per cent., and more. Other advantages accruing from such a change in the lamp standard might be mentioned, but enough has been said to indicate the far-reaching nature of the high efficiency lamp.

Of late a tendency has made itself manifest towards the use of high voltage, that is, 220 volt lamps. In principle the adoption of such a lamp is desirable as economical on the side of conductor cost, but we do not look upon this matter as of the same degree of importance as that attaching to the higher efficiency lamp. As a matter of fact the high voltage lamps manufactured at present have an efficiency not exceeding 4 watts per candle, so that even to-day their employment is advisable only under special conditions.

The difficulties standing in the way of a successful 220 volt lamp will be apparent when it is considered that a 3.1 watt lamp must have a given surface per candle and that a lamp to operate at the same efficiency, but at higher voltage must have a resistance proportional to the square of the voltage. This would mean that a 50 watt 220 volt lamp would require a filament one-half as thick and twice as long as that of a 110 volt lamp; this would call for a filament 2½ thousandths of an inch in diameter and 18 inches long. Incandescent lamp makers will better than any others appreciate what this means.

Looking at the subject broadly, there are two directions in which the light-giving efficiency of the incandescent lamp may be increased, and these are, (1) by increasing the temperature at which the filament is run, and getting the filament to stand that temperature; and (2) paradoxical as it may seem, to give the filament a much poorer radiating surface, so that at the same temperature it will yield more light rays and consequently give more light for the energy expended, as pointed out by Mr. John W. Howell in a communication appearing on another page.

It would seem problematical whether incandescent lamp filaments could be run at higher temperatures than those now in vogue without decreasing the life of the lamp; or rather would it appear that more encouraging results may be looked for in the other direction mentioned above. Some experiments have already been made with this end in view, in the application to the filament of the rare earths which give out a large proportion of light when heated to incandescence, a property so well utilized in the Welsbach lamp.

It must not be forgotten that since incandescent lighting became an established industry, its competitor gas has received more attention than it did during its whole preceding life, and with corresponding results. The last 15 years have witnessed not only a remarkable reduction in the cost of production of the gas itself, but decided advances have been made in increasing its light giving value.

We do not believe that gas in any improved form or appliance can ever succeed in driving the incandescent lamp from the field, or in ever more than temporarily affecting its progress, but the experience of the last few years seems to lead to the conclusion that it might be desirable to increase the present 16 candle-power standard to, say, 20 candle-power. The former standard was adopted originally to conform to the then existing standard, or rather to measure up favorably against the average gas burner, but the present standard of the latter has increased and the incandescent lamp might with advantage, perhaps, be brought abreast of it. Nor must it be forgotten in this connection that the incandescent lamp has an electrical competitor in the arc lamp, a rival by no means to be despised in some respects. Nevertheless when one considers the odds against which the incandescent lamp has had to struggle, it speaks volumes for its inherent staying powers, that its use has never for an instant shown a decline, but is, on the contrary, constantly on the increase, at an increasing ratio of growth.

POINTS ON CAR FARES.

It seems difficult to get some papers to do even the barest justice to the street railway companies. Here is an example from the New York "World":

"Commissioner Meriwether, of the Missouri Bureau of Statistics, has made an exhaustive study of the subject of street railway franchises and cheaper fares. Among other facts illustrating the possibilities of a reduction to three cents without crippling the companies, he cites the result in Glasgow, where with a maximum charge of a penny a mile the business has returned 10 per cent. dividends after paying fixed charges. Such facts seem hardly credible in communities accustomed to paying five-cent fares, but they will become credible finally and then fares will come down."

Now this "illustrates" nothing of the kind, and having ourselves tried the Glasgow cars we know practically that it doesn't. In this country the 5-cent fare (or 2½ pence) will carry a man far more than 5 miles. On Manhattan Island it carries a passenger from the Battery to McComb's Bridge, a distance of nearly twice five miles; and the passenger rides in comfort and convenience that is hardly dreamed of in Glasgow, which city has just sent experts over here to learn how our street railway companies do things, it is so far behind the times. If the New York "World" wants a scale of fares based on "a penny," or 2 cents per mile, that is quite another question. The American public appears to have a decided preference for the flat rate, one fare, which encourages the settlement of people with moderate incomes in cheap homes in the suburbs to an extent the European knows nothing about. The street railway companies are perfectly willing to take three cents but they will no longer be able to give the bulk of their patrons six cent rides. Besides, it is not yet proven that the Glasgow system is really paying its way and taking care of all charges and depreciation, let alone earning 10 per cent.

STEAM ENGINES AND ELECTRICITY.

Among the contributions which we print in this issue is one not devoted specifically to an electrical topic, but which is worthy of the most earnest consideration by all interested in the generation of electricity. For while we may be on the threshold of important practical advances in the generation of electric current direct from carbon, we shall still be required to employ the steam engine as our source of power for some time to come. Any advance in that direction is bound to make its influence felt in electrical work, and no better evidence of this fact could be desired than the history of the steam engine in relation to electric lighting and power work during the last fifteen years. Prof. R. H. Thurston makes this aspect of the question the subject of an admirable essay which we print on another page. It shows in a clear and concise manner just where the art stands to-day in steam engine economy and what we may hope for in the future. There is evidently one principal direction in which advancement lies and that is in the use of higher pressures. The curves of steam economy accompanying Professor Thurston's article are particularly instructive as showing the performance and relative place of the actual engines of to-day.

BEGINNING THE NEW VOLUME.

As a general thing the changes introduced in The Electrical Engineer from year to year are slight. The style and size of page adopted at first, 16 years ago, has proved excellent and more and more weekly journals, including those in the electrical field, have come to it. Outside of that, changes are limited to typographical arrangement, and this year the Engineer has made a few changes looking chiefly to ornamentation and the closer classifying of the matter. The List of Contents has been transferred to the last page in order to secure more room for the editorial discussion of questions of the hour.

THE PASSING OF THE DRIVING PULLEY.

BY SCHUYLER SKAATS WHEELER, Sc., D.

(Prest. Crocker-Wheeler Electric Co.)

THE industrial arts have probably never experienced a more rapid and positive growth of a new principle than the acceptance and development of direct electric power has shown in the three years just ended.

Such rapidity of advancement especially in view of the expensive nature of the materials involved (machinery) and the necessarily conservative nature as a class, of those practicing in these arts, point positively to one truth—a high ratio between the economic advantages obtainable, and the disadvantages, of all kinds, represented by the labor, expense and delay of making the change. In the language of the electrician, the Rapidity of Adoption equals the Incentive divided by the Difficulties.

The electric transmission of power has now, and since the comparatively recent publication of some rather full descriptions of work in this line by the writer, become so far standardized that practically all makers of machinery are now accepting or soliciting orders for their products arranged for direct electric driving. It has for some time past been well pointed out that while a motor geared or belted to a tool presents considerable advantage over belt connection from a shaft, greater simplicity as well as power economy can be gained by partially re-designing the tool so that the motor can be incorporated into it closer to the working part; as, for example, with its armature upon the drill spindle of a swinging arm drill, or on a shaft removed by one reduction from the arbor of a miller or lathe. Heretofore all machinery, being belt driven, has necessarily been designed with reference to the necessity of multiplying up or reducing from the speed of its cutting parts by suitable gearing so as to attain the speed at its point of mechanical driving, which is suited to the frictional capacity, best speed, etc., required in practice with belts. Belts often, therefore, require wheels to receive them, and supporting bearings, with extension enlargements and modifications of the frame of the machine, with trains of gearing which absorb power, that are no longer necessary with the electric motor directly applied and—the passing of the driving pulley.

LONG DISTANCE TRANSMISSION.

BY CHARLES P. STEINMETZ.

(Elec. Engr. General Elec. Co.)

ALREADY in the early days of electrical engineering, 20 years ago, high alternating potentials were used for series arc lighting. With the advent of the arc lamp these alternating circuits disappeared and continuous current arc circuits were established with voltages rising with the increasing extension of the lines, apparently without being considered as particularly dangerous. The stationary transformer introduced the alternating current system again, now as constant potential system for incandescent lighting, with primary lines of 1,000 volts, and later on occasionally 2,000 volts, the latter voltage, however, being considered as dangerously high. Still a few years ago, when with the further extension of alternating circuits an increase of generator voltage became necessary, 3,000 volts was considered as too high a generator voltage, and 2,500 volts was adopted, but fortunately soon discarded in favor of 3,000 volts; and at present as standard primary distribution potentials 1,000, 2,000 and 3,000 volts are used with an over compounding of the generators up to 20 per cent. to cover losses in lines and transformers, giving thus a range of voltage up to 1,200, 2,400 and 3,600 volts, respectively.

Primary distribution plants now are installed mostly at 2,000 volts, very few at 1,000 volts, but quite a number at 3,000 volts. One of the largest systems installed has adopted 4,000 volts for distribution, and in a few special cases 5,000 volts is used, with a range of generator voltage up to 6,000 volts. This latter voltage, however, is still very seldom considered for distribution, but is quite frequent for long distance transmission directly from a high potential generator. A number of such systems are in operation, and even 10,000 volts directly produced in the generator is taken into consideration.

At these higher transmission voltages, however, step-up transformers are generally used with low voltage generators. Gradually the practice has established itself to cover the range up to 5,000 or 6,000 volts by direct supply from a high potential alternator and to use step up transformers from 10,000 to 12,000 volts.

Most of the long distance transmissions now installed are either at 5,000 to 6,000 volts directly fed from the generator, or, where the distance is greater, 10,000 volts at the receiving end of the transmission line is used, with step-up transformers, and the generator voltage under load raised to cover the drop of voltage in the transmission, thus giving a range of line voltage of 10,000 to 12,000 volts. No large plant of higher voltage than this appears to be in commercial operation in this country, but distances of thirty-five miles (Fresno) have been covered by this voltage.

The difficulties, due to the high voltage in lines and apparatus, have in these years of development decreased, that is, the methods of insulating line and apparatus have developed faster than the voltage has been increased, so that the present 10,000 volt transmission is far more reliable in its operation than the 1,000 volt circuits of the early days.

Ten thousand volt transmissions seem to be safe to operate in any climate. If, however, a considerably higher voltage should be chosen for the high potential transmission line, a consideration of the climate in which the line is to be operated seems to become necessary.

Naturally a considerable amount of work, theoretical as well as experimental, had to be done before these high voltage transmissions, now so numerous, could be undertaken. The effect of high alternating potentials has been investigated very carefully, not by electrostatic machines or Leyden jar discharges as in the early days, but with large transformers and engine power behind, for voltages up to and beyond 160,000 volts effective or 230,000 volts maximum, voltages which will jump over 16 inches of air and pierce practically any insulation.

The present extended use of high potential transmissions became possible only by the development of the alternating current motor. As long as alternating currents were suitable only for lighting but not for motor work, their field of application was limited. The stationary motor as day load offered a more uniform load curve, and the rotary converter and synchronous motor opened the whole field of electric railroading to the alternating current transmission. At present such transmissions have developed in three fairly distinct directions.

1. Long distance transmission of mechanical power.—Generator and synchronous motor are connected together through the high potential line, either directly or by step-up and step-down transformers. The alternating current line is here equivalent to a belt connection between the turbine shaft and the synchronous motor shaft miles away. The whole installation is usually very simple, generator and motor kept at constant excitation at all loads, and thus the voltage in the line is only approximately constant but varies with the load.

2. Long distance transmission for distribution to lights and stationary motors.— Here the high potential line terminates in the step-down transformers at the receiving substation. This substation is in all its features equivalent to the central station of an ordinary electric light and power distribution, the step-down transformers taking the place of the generators. The distributing network is fed either directly by alternating currents from the step-down transformers on a low tension system with mains and feeders, or a high tension system with 1,000 or 2,000 volts distributing lines and individual transformers, or a combination of both, using low tension distribution in the center of the city and reaching further outlying districts by high tension lines. Or distribution takes place by a continuous current three-wire Edison system through rotary converters. Even in the latter case, however, larger motors are frequently connected directly on the alternating circuit.

In such a system of long distance transmission for distribution to lights and stationary motors, all generators are operated in parallel and mostly separately excited by a turbine driven exciter. The excitation is controlled so as to maintain constant voltage at the center of the secondary distribution, and the distributing lines leading from the substation are controlled by induction regulators.

Transformation to continuous current by rotary converters allows the use of three wire mains and feeders in the low tension distribution and permits of connecting directly to, and feeding into, existing direct current systems. The distribution by alternating currents requires four wire mains for economical distribution on the low tension system, but avoids the losses in the rotary converters and the necessity of using large rotary machinery in the substation. Thus a decision whether alternating currents or continuous currents are preferable in the distribution system generally depends upon the local conditions.

3. A distinctly different branch the long distance transmission for electrical railroading, has been developed. Even in large stations railway load fluctuates so greatly and suddenly as to make it desirable to separate the railway load altogether from the lighting load, except where it constitutes only a small proportion of the total load. The load fluctuates too rapidly to make hand regulation of the generator excitation practicable. Thus an automatic system of control had to be devised, in which the generators are kept at constant excitation and the control of voltage in the whole system effected by varying the phase relation in the alternating current circuit, in a manner wnich can best be explained by the description of some of the existing plants.

In the transmission from Oregon City to Portland two high potential generators at Oregon City of 450 kilowatt each, are used for railway work, and supply over separate high potential lines two rotary converters of 400 kilowatt each. The generators are kept at constant excitation corresponding to 6,500 volts at open circuit. The length of the line is 14 miles, the loss of energy in line and step-down transformers about 10 per cent., the resistance voltage about 20 per cent. at full load. The generators feed directly into the transmission line and with constant excitation, in the absence of phase control, over 600 volts would be found at no load and less than 500 volts at full load at the continuous current brushes of the rotary converters. The rotary converters, however, are supplied with a very weak shunt field and a very powerful series field. In consequence thereof they are greatly under-excited at light load, so that their counter e. m. f. is considerably below the impressed e. m. f. In consequence thereof they take a considerable lagging current over the line at no load. The e. m. f. of self-induction in generator and line is 90 degs. behind the current and since the current is lagging behind the e. m. f. of the generator, the e. m. f. of self-induction is practically in opposition to the induced e. m. f of the generator and subtracts itself herefrom, bringing the voltage down to 500 volts at the commutation brushes of the rotary converter at no load.

With increasing load the excitation rises, due to the series field of the rotary, until at full load the rotary converter is greatly over excited and its counter e. m. f. beyond the impressed e. m. f., and thus the alternating current forced to assume such a phase relation as to demagnetize the converter field. That is, it is made leading. With a leading current, the e. m. f. of self-induction, which is 90 degs. behind the current, is nearly in phase with the induced e. m. f. of the generator and thus adds itself thereto, and increases the voltage by what may be called partial resonance, so that at full load, although the current is very much larger than at no load, the drop of voltage between generator and rotary converters is greatly less, the drop due to the resistance being compensated for by the rise due to self-induction and leading current. The voltage at the commutator brushes rises from 500 volts at no load to 550 volts at full load.

This control of phase relation is perfectly automatic, gives a minimum amount of idle currents in the system under load, and has proved very satisfactory wherever it has been installed for long distance railway transmission, as, for instance, in the plant mentioned above, which has been in continuous operation for several years and is being extended at present.

THE ACCOMPLISHED UTILIZATION OF NIAGARA.

BY W. B. RANKINE.

(Secy. Niagara Power Co.)

IN response to your request for succinct data as to the net result of the enterprise at Niagara, in regard to which The Electrical Engineer has made so full a record during the past six years, I am glad to be able to submit figures of a remarkably encouraging character. The project has never promised so well as now, either in practical operations or in those financial results which, as Mr. Brunel insisted, can alone justify even the greatest engineering plan.

Since work was begun in 1890, we have had at least four financial crises, and other influences, deterring the establishment of new industries requiring power. Considering these general and well-known adverse conditions, coincident almost with its life, the wonder is that this company has steadily progressed, and, as above indicated, has virtually reached the point of self-support. Under such conditions, and in view of the necessarily experimental character of the work, it would have been folly at any earlier date to seek to provide for an installation larger than necessary to demonstrate that this enterprise can accomplish real work and promise real profits.

The plans of the Cataract Construction Company and the works of the Niagara Falls Power Company are so far completed that delivery of power to customers in Buffalo has been successfully instituted, and the calls for power under contracts actually executed (and in excess of the present capacity of the works) will provide annual rentals which, with contracts in negotiation, represent a total income from that source falling not far below half a million dollars.

The present electrical installation comprises three dynamos, each of 5,000 electrical horse-power, of which one should be kept as a reserve; but the demand has made such reservation impossible, and the contracts already made for 15,825 electrical horse-power exceed not only the prudent, but the actual, capacity of these works, which require immediate extension, with every prospect of prompt and profitable employment.

The proposed extension involves doubling the present capacity of the transmission line to Buffalo which already in successful operation, is delivering 1,000 electrical horse-power; the extension of the wheel-pit for its full length, so as to have capacity in all for ten 5,000 horse-power turbines and dynamos; the installation of seven 5,000 horse-power turbines and dynamos, in addition to the three now in operation; and the extension of the power house to cover the new installation. The work of such an extension of the wheel-pit is about one-third completed; the right of way from Niagara Falls to Buffalo is complete; the pole-line already erected has a pole and cross-arm capacity for 20,000 electrical horse-power, with copper conductors in place for 5,000 electrical horse-power. Upon definite proposals already received, the entire installation above described can be accomplished within the year 1897.

As a concrete presentation of the facts, I will add a list of the contracts for power up to election day, 1896. No more eloquent statement as to results achieved could be given if I were to fill a volume of your journal:

HYDRAULIC POWER.

	H. P.
Niagara Falls Paper Co	7,200

ELECTRIC POWER.

Pittsburg Reduction Co. (aluminum)	3,050
The Carborundum Co. (carborundum)	1,000
Acetylene L. H. & P. Co. (calcium carbide)	1,075
B. & N. F. Elec. Light & Power Co. (local lighting)	500
Walton Ferguson (chlorate of potash)	500
Niagara Electro-Chemical Co. (peroxide of sodium)	400
B. & N. F. Electric Railway (local railway)	250
N. F. & S. B. Railway Co. (local railway)	250
(All from October 1, 1896.)

(From November 15, 1896.)	
Acetylene Light, Heat & Power Co.	
(From February 1, 1897)	1,000
(From March 1, 1897)	1,000
(From delivery, say, November 1, 1897)	2,000
Mathieson Alkali Works (soda ash)	
(From June 1, 1897)	2,000
Buffalo Street Railway Co	1,000
Buffalo General Electric Co. (lighting)	3,000
(From November 15, 1897)	
Totals	25,225

SUMMARY.

Total hydraulic power sold—Niagara	7,200
Total electric power sold—Niagara	13,025
Total electric power sold—Buffalo	5,000
	25,225

ADDITIONAL.

Albright & Wilson, Ltd (electro-chemicals)	400
1896—Grand total	25,625

It will be obvious, at a glance, that Niagara has already started on its career as a great chemical center, and thus justifies the predictions that the chemical trades would center ultimately around the sources of cheap power in large quantity.

TELEPHONY AND TELEGRAPHY

FIFTEEN YEARS OF TELEGRAPHY.

BY WILLIAM MAVER, JR.

(*Author of "American Telegraphy."*)

ALMOST contemporaneously with the beginning of this journal, there was introduced one of the most important innovations that had taken place in the practical operation of the telegraph, namely, the use of the dynamo machine in place of gravity battery for the purpose of generating the electromotive force necessary to the transmission of telegraphic signals. This application of the dynamo machine was first persistently advocated and finally successfully exploited both to meet the requirements of ordinary Morse as well as duplex and quadruplex telegraphy, by Mr. S. D. Field, about the year 1880. The dynamo machine was at first only applied to the main or trunk lines of the telegraph service, but it was, and now is, very generally utilized also for the "local battery" service. From the first installation it may be noted that this innovation was a marked success. More recently the storage battery has been largely utilized by telegraph companies for these purposes also and it is probably within bounds to place the number of gravity cells displaced by these two agencies at not less than two hundred thousand. Not the least of the advantages derived from this change is the great saving of space in places where space is very valuable, but at the same time the economy of operation is great, and the reliability and generally improved service derived from the use of the dynamo and storage battery have been very marked. Storage batteries were also used in telegraphy in England at least ten years ago, and by Mr. S. D. Field in San Francisco in 1878.

Another noteworthy and exceedingly important advance in the practice of telegraphy within these past fifteen years has been the more or less general use of hard-drawn copper wire in place of the galvanized iron wire so almost universally employed for aerial wires before 1884, which was the year in which began the extensive use of hard-drawn copper wire for telegraph purposes. From its inception the use of this wire was a success, and its importance can scarcely be overestimated. For not only does its superior electrical qualities, as compared with iron, give it decided advantages, but without these advantages its vastly greater durability would render its employment highly advisable, now that it has been shown to possess the other mechanical qualities essential to a successful telegraph wire. In point of durability, when exposed to the ordinary elements in the atmosphere of town and country, there is really no comparison, the average life of an iron wire being probably not over 12 years, at the end of which time, owing to the effects of corrosion, it is virtually useless for any purpose; while the life of a copper wire, so far as the effects of corrosion are concerned, is apparently unlimited, and if for any reason it should be put out of service it still retains an important value as metal.

The size of the hard-drawn copper wires thus first erected was No. 14 and No. 12, weighing, respectively, 110 pounds and 170 pounds per mile. The copper wire now much used in this service weighs about 200 pounds per mile. An idea of the vast amount of copper thus utilized may be gleaned from the fact that in a 20-wire pole line between New York and Buffalo, a distance of nearly 440 miles, 880 tons of the metal would be necessary, not counting the tie wire.

With regard to the art of telegraphy, so far as relates to the methods of transmitting signals that have been adopted, it cannot be said that any very material progress has been made within the past 15 years. It was prior to that period, about 1876, that the last notable advance was made in this direction, namely, the successful introduction of the quadruplex by Edison, by means of which the existing wire facilities were, at a bound, virtually quadrupled, or as compared with the duplex system which had only recently been perfected at the time of the advent of the quadruplex, practically doubled.

It is known also that the Wheatstone automatic system has been introduced within the time mentioned upon the lines of one of the telegraph companies of this country, with a certain amount of success, but its application has not been by any means general, which is in marked contrast to the practice in this respect in Great Britain where this system is very largely employed, more especially in the transmission of press dispatches.

In connection with this latter system it may be noted that a very important improvement in the speed of signaling on combined aerial and short cable circuits has been obtained in the latter country, by an ingenious arrangement of condensers around and about the differential coils of the relays, but the writer is not aware to whom credit for the arrangement is due. Messrs. Preece and Sivewright, who give statistics and other information on this subject, show that on certain circuits the speed of signaling has been increased fully 100 per cent. by means of this simple device.

Another noteworthy improvement in telegraphy within recent years is that in which it is combined on the same wire or wires with telephony, thereby giving a system, or method, termed simultaneous telegraphy and telephony. This combination was first made practically possible, it is believed, by the "graduating" devices of Prof. F. Van Rysselberghe, by means of which the telegraphic currents were rendered harmless in their effect upon the telephone receiver. This system has been in operation in Europe for a number of years and it is now in operation in this country somewhat extensively, and it is understood quite successfully. When it is considered that the two wires of the metallic circuit of long distance telephone wires may be simultaneously employed as single Morse wires, without practical interference the one with the other, the value of this combination will be the better appreciated. And in fact the practicability of operating both of the wires of the metallic circuit as Morse duplex circuits was demonstrated several years ago. The writer is not, however, aware that this latter arrangement is at present practiced.

In the direction of rapid signaling by chemical automatic methods, nothing has been done in actual practice recently. This field has not, however, been entirely neglected, for the well-known inventor, Mr. P. B. Delany, has been at work perfecting a chemical automatic system which has several marked advantages, chief of which is his plan of indicating the dots and dashes, not by long and short marks, as hitherto, but by giving these characters a different position on the received slip. The great obstacle to fast signaling by chemically prepared paper, namely, "tailings," is thus very measurably overcome or rendered nugatory.

In the line of fast printing telegraph systems it may be noted that Mr. C. L. Buckingham has devised apparatus capable of transmitting and receiving at the rate of over 100 words per minute, but the system has not as yet gone into practical operation.

One other somewhat recent improvement in telegraphy which may be noted, is the Delany synchronous telegraph system, which is now in operation in Great Britain and by means of which form four to six messages may be transmitted over a single wire in either direction at the same time, and to this extent it excels the quadruplex, the limit of which is the transmission of two messages in both directions concurrently. It is also well understood that the Delany synchronous system may transmit a much larger number of messages in either direction on circuits of moderate length and capacity.

In overland telegraphy the apparatus employed both in single and duplex and quadruplex working has been materially improved, one tendency being to the use of a lighter metal, such as aluminum, wherever possible. Another advance has been in the adoption of the typewriter by the operators almost generally in the large offices in this country, as a means of copying dispatches as they are received.

In long submarine cable telegraphy within the past decade and a half the improvements have related mainly perhaps to speedier signaling, and as a means to this end may first be mentioned the Muirhead "double block" arrangement of condensers which displaces the usual ohmic resistances in the arms of the Wheatstone bridge. The device is said to have increased the speed of signaling by about 15 per cent. The intrinsic value of this improvement is greater than at first sight appears, for, taking the average rate of speed on the Atlantic cable duplexes to be now 25 words per minute, each way, this improvement added a capacity of, say, 8,000 words per day to each cable. This at 25 cents per word adds practically three-quarters of a million dollars per annum to the earning capacity of the cable.

Another improvement in the operation of long submarine cables was the introduction of the Cuttriss magnetically vibrated siphon recorder, which in a more or less modified form is now in use on the majority of such cables. The utility of this device consists in the avoidance of the delays that frequently occurred in the highly ingenious electrified ink siphon recorder of Lord Kelvin, which delays were due chiefly to changes in atmospheric humidity.

Still another recent improvement in the details of operation of cables is the utilization of automatically transmitted signals. The messages are prepared for transmission in a manner analogous to that employed in the preparation of messages for transmission by the Wheatstone automatic system, namely, by punching holes corresponding to dots and dashes on strips of paper. These strips are then passed through an automatic transmitter, but of course at a speed not much, if anything, greater than is possible by manual transmission. The aggregate gain over manual transmission is, however, perceptible, a result which is due to the fact that the maximum capacity of the cable is utilized, the transmitter being automatically kept at the top speed of transmission, and thus no time is lost by the varying speeds of an operator, or by the practically unavoidable delays caused by the operator in pausing to decipher an obscure word of a message, this latter delay now occurring at the punching apparatus. Another advantage due to this employment of the automatic transmitter is that the respective characters of the signals as received on the siphon recorder are much more uniform than when transmitted manually, and are therefore more readily deciphered.

In this relation it may also be noted that Mr. W. P. Phillips has recently introduced upon the New York-Washington lines of the United Press Association an improved automatic sender which is giving very satisfactory service. The messages as prepared for transmission by this sender are embossed on a paper strip by a Morse "register," excepting that the embossings are in duplicate or triplicate, as desired, longitudinally,

. —— ——. . . . . .
thus, . —— ——. . . . . . etc., the subject matter
. —— ——. . . . . .

being sent to this register on a local circuit by expert operators. The embossed paper is passed under the lower end of a rigid vertical lever which is suitably pivoted. At the upper end of the lever are placed the contact points corresponding to those of a Morse key on a main line circuit. Normally, as when there are no embossings under the lever, a retractile spring draws the lever into a position where the main line circuit is open. On the contrary, when one of the raised characters is under the lever, it is pushed toward the contact point, closing the circuit for a time corresponding to a dot or dash. The embossed paper is caused to pass over an upwardly rounded plate, and in thus passing it is caused to conform to the shape of that plate. By this arrangement the raised character is drawn abruptly down from the end of the rider, giving the latter free course to return to its normal position between each character. On the New-York-Washington line, press matter is easily transmitted by this device at the rate of eighty words per minute. At the receiving stations, similar Morse registers are employed to receive the matter at this rate of speed, and the paper strips thus embossed are then passed through another automatic sender in a local circuit containing a Morse sounder. The speed of this sender is regulated to suit the capacity of the receiving operator. This automatic sender gives virtually the capacity of two wires operated on the ordinary Morse method.

The spread of the telegraph network throughout this country still continues; the largest telegraph company here having opened an average of one new office every day during the past year.

The increase of mileage of telegraph wire in this country has increased from about 350,000 miles in 1882 to probably 1,000,000 miles at the present time. If, however, it be assumed that 20 per cent. of the existing wires were equipped with duplex or quadruplex apparatus in 1882 and that 25 or 30 per cent. are thus equipped to-day, the increase of actual wire facilities will be considerably greater than appears on the surface; in other words, approximately, in the ratio of 420,000 miles in 1882, to 1,300,000 in 1896.

At the same time, judging from available figures, it is probable that the amount of business handled by the telegraph companies of this country for the past few years has not kept up to that of the immediately preceding years. The general depression in business has doubtless accounted for considerable of this probable loss, but it is also likely that the keen competition of the telephone has weighed largely in bringing about this result. Another explanation of the lack of material increase in the number of messages transmitted telegraphically in this country during the past few years has been found in this, that many of the best patrons of the telegraph service have considered it advantageous to lease wires for their own use. Notwithstanding all of which, however, the aggregate number of telegraph messages transmitted during the present year in this country, probably exceeds the number sent fifteen years ago by fully twenty-three million, not, on the whole, an insignificant increase.

If now, confining one's self to this country, one might venture a prediction as to the future progress of telegraphy—a thing which custom makes permissible, and, indeed, almost renders obligatory when retrospections have been indulged in—it would be that if, fifteen years hence, the historian of that period shall be able to chronicle the fact that the telegraph companies (or will it be the government telegraphs?) of that day have handled twenty-five million more messages during the year then closed than were transmitted the fifteenth year previously, this feat will have been accomplished, it is safe to say, by a radical change in the present methods of the telegraph service. For if the encroachments of the telephone into what has been, until recently, the exclusive domain of the telegraph, are to continue, it is seemingly evident that any such increase as that just intimated must be obtained by catering to, or possibly by creating, a class of service with which the telephone cannot compete. Will this be in the direction so strongly urged by Mr. Delany and others, namely, by offering a service analogous to the postal mail service, or what? And will the methods of transmission and reception of business remain as at present, or will resort be had to automatic or printing telegraph methods? Time will tell.

FIFTEEN YEARS' ADVANCE IN SUBMARINE CABLEGRAPHY.

BY GEO. G. WARD.

(*Vice-President, Commercial Cable Co.*)

THE improvements and advances in submarine telegraphy may fairly be judged, I think, from the work done in the North Atlantic, where I have necessarily enjoyed special opportunities for watching and noting the effect of the various changes tried, abandoned, or adopted, as part of a great system uniting the two most active and progressive portions of the human race.

It seems to me that there are three main points in which submarine cable work, as exemplified by the conditions in the North Atlantic, has made great strides since The Electrical Engineer was founded in 1882. In the first place, the facilities have been greatly increased. In the second, the rapidity and legibility, and, consequently, the accuracy of transmission have been much improved, chiefly by resort to better cables and perfected terminal apparatus. In the third place, the service has been so cheapened that it is within the means of almost every one to use the cable, and in nowise be called extravagant.

The increase of facilities lies not so much in the greater number of cables as in the quality and better disposition of the new ones. In 1882 there were eight cables in operation. Now there are eleven. But in 1882 there was not a single cable coming direct into New York City, and it was a common thing for communication between the great centers of European and American commerce to be interrupted for periods of serious duration. In 1884 the first great step in providing reliable communication was made when the Commercial Cable Company laid two cables across the Atlantic and breaking through the traditional practice of landing in out-of-the-way places for fear of shipping, boldly brought a connecting cable into the craft laden waters of New York Bay.

This enterprise has been amply justified and rewarded, for no cable has been less subject to interference or damage. From the moment it was laid communication has been permanent. It is a matter of history that this cable has been the only means by which any intelligence could be brought into or sent out of New York City and has been availed of for sending messages by way of Europe back to Boston and Montreal for distribution to other cities on this continent. Other cables have since been brought to New York, so that now it seems almost impossible that communication can ever be interrupted.

As to the advances in the rapidity of transmission there is record of a bona fide transaction between Manchester, England, and Victoria, British Columbia, in ninety seconds. One can hear daily in the Cotton Exchange of New York City messages read from the rostrum officially timed as having left Liverpool one or two minutes previously. Only recently the Commercial Cable Company was complimented for transmitting a message filed at Liverpool at 2:59½ p. m. in time to transact business before the New York exchange closed half a minute later. So steady, rapid and reliable is the work of the Atlantic cables that merchants are inspired to take such extreme chances.

The rapidity and accuracy of ocean telegraphy is achieved by the increased conductivity of modern cables, improvements in Muirhead's system of duplex telegraphy, Wilmot and Cuttriss automatic sending instruments, Dickenson and Cuttriss forms of receiving coil suspension and adjustment, and Cuttriss vibrator.

Added to these and as important as any is the marvelous skill of the trained cable operator. Carefully compiled statistics show that one error occurs in about ten thousand words. Individual operators succeed in preserving a faultless record, but the standard is one error in thirty to forty thousand words. In the majority of instances the errors are telegraphically trifling and inseparable from the hazardous nature of the business. To any one familiar with the details of long cable working and the character of the words used in cablegrams, these results are simply wonderful.

Considering the fact that the actual earnings of the Atlantic cables has remained practically a fixed quantity for the last 15 years, notwithstanding the increased number of cables and the reduced rates, I think the public has reason to be satisfied with the service they receive and the price they pay for it. I have no hesitation in saying the Atlantic cable service has been brought to a high state of perfection and is to-day the best in the world. In 1882 the rate was 50 cents per word. In 1884 the Commercial Cable Company appeared on the scene and opened for business with a 20 per cent. reduction, which led to a tariff war lasting upwards of two years. Finally a common agreement was entered into between all the companies, fixing the rate permanently at 25 cents per word.

One point that impresses me is the larger use of the cables by the press, encouraged by the liberal rates and facilities inaugurated by the Commercial Cable Company. European and American newspapers to-day receive the bulk of their foreign news by cable. They no longer confine their dispatches to reports of battles and great political events, but use the cables freely to inform their readers on trivial matters, fashions, society gossip, storm predictions and even the state of the weather at distant places.

I have watched closely the efforts made within the fifteen years to telephone across the ocean. I do not say that this will never be done; I can only record the fact that the attempts have not been successful thus far.

Considered from a practical point of view, with the enormous capital outlay invested in an ocean cable, I do not see how ocean telephony can become commercially available. At the present time, in order to return a fair profit on the amount of capital invested, every second of time has to be usefully employed during business hours. A merchant can send a cablegram for 75 cents. If the telephone were employed, taking the present charges for long-distance telephony in the United States as a standard, a five minutes' conversation between New York and London would hardly cost less than $75, an obviously prohibitive price for any extended use.

With the perfect methods of duplexing and within the limits of the recording instruments now in use, the cables already yield all the speed that is obtainable from the materials used and manner of their combination. Greater speed can be obtained by increasing the size of the conductor, but with the increased size of the conductor practical difficulties arise in the handling and laying of the cable and the recovery of it in case of damage. Further, it is better practice to lay two moderate-sized cables than one very large one. Therefore increase of speed can hardly be looked for with the present type of cables unless a recording instrument can be devised, the moving parts of which have little or no inertia. Photography has entered the field and results have been obtained which are highly interesting, but of which the practical value cannot yet be estimated.

Several novel features of construction of cables have been proposed in order to overcome the retarding effects in long cables, but although much is to be hoped for from investigation and experiment, nothing has yet been suggested that attracts the serious attention of practical men.

THE USE OF A MID AIR TELEPHONE WIRE WITH KITES.

BY WILLIAM A. EDDY.

On December 5, 1896, I sent aloft a pilot kite at 4:30 p. m., arrangements having been made with Dr. William H. Mitchell, an electrical experimenter of Bayonne, N. J., where my telegraph and telephone experiments with kites were carried out, to begin the work as soon after dinner as possible, about 7 p. m. I found the wind extremely weak, probably not over 5 miles an hour at the earth, and for that reason I sent up a very light tailless kite covered with very thin manilla paper, and having very light sticks. It was a tailless kite, known throughout the world as the Eddy kite, devised in 1891, and presented to the public free of patent in 1892. It is the kite which I introduced at Blue Hill Observatory, ten miles south of Boston, in 1894, with which, using nine kites in tandem, I reached an altitude with my top kite at Bayonne of 5,595 feet on November 5, 1893. With seven of these kites, assisted near the base of the line with two Hargrave kites, an altitude above sea level of 9,385 feet was reached at Blue Hill Observatory on October 8, 1896, which is undoubtedly the highest kite altitude ever reached in the world. This great ascension was managed by Clayton, Fergusson and Sweatland.

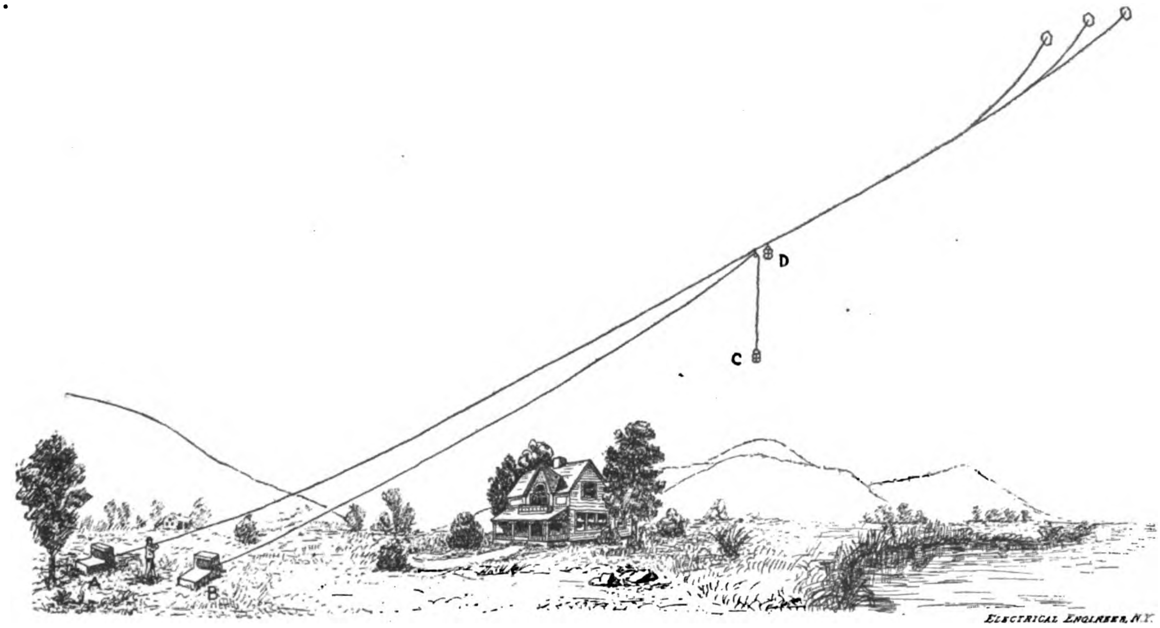

FIG. 1.—EDDY KITES SUPPORTING TELEPHONE CONDUCTOR AND LANTERN.

With a number of these kites flown one above another on the main line I have long been at work at Bayonne, from 1890 to 1891 with tail kites, and from 1892 to 1896 with tailless kites, lifting many different kinds of experimental apparatus, such as small aeroplanes, lanterns, flags, silvered reflectors, and electric wire and tinfoil collectors, collectors in the sense that an open frame with netting was coated with tinfoil and sent up into the air where it collected atmospheric electricity. I was preceded in this atmospheric electric experiment by Benjamin Franklin in 1752 and Alexander McAdie at Blue Hill Observatory in 1885, both of whom used tail kites.

During my atmospheric electric experiments I found that in dry weather it was necessary to send my collector to a heigher point in the air than in moist weather. I proved this by measuring the humidity with wet and dry bulb thermometers.

I had two or three thousand feet of thread-like copper wire which was bare of insulation and which was ready to be paid out upward along my heavy kite cable, which by 7 p. m. was well sustained in the air by the first pilot kite just mentioned (6 feet in diameter), and two slightly heavier kites, 7 feet in diameter. The wire had been used in atmospheric electric experiments with success; it was wound on a reel with movable spools which could be replaced in case the wire ran out.

About 7:30 p. m. Dr. Mitchell, the electrician, arrived on the open lot from which the kites were flying with one lantern aloft. The wind declined, and the pull of the kites, which were flying toward the northeast, became so weak that for a time I feared it would be necessary to defer the experiment. Luckily the wind strengthened, and by 8 p. m. the wire was paid out from the wire reel across the lot to a point on the kite line about one hundred feet from the kite reel. The kite cord was then run down to meet the end of the wire which was passed through three harness rings fastened across the kite line and bound to a rigid piece of bent wire. A permanent red lantern, D, Fig. 1, was attached near the rings to show the point at which the running wire was suspended from the kite cable. Then the kites were paid out from the kite reel, A, and at the same time the bare wire was paid out from the reel, B, while a plummet lantern, C, was fastened to the end of the running wire. If I stopped the kite reel and paid out the running wire then the lantern was to descend rapidly some distance away beyond intervening obstacles; while if I stopped the wire reel and at the same time paid out the kites upward and away from me, then the lantern would rise in the air as the kites receded.

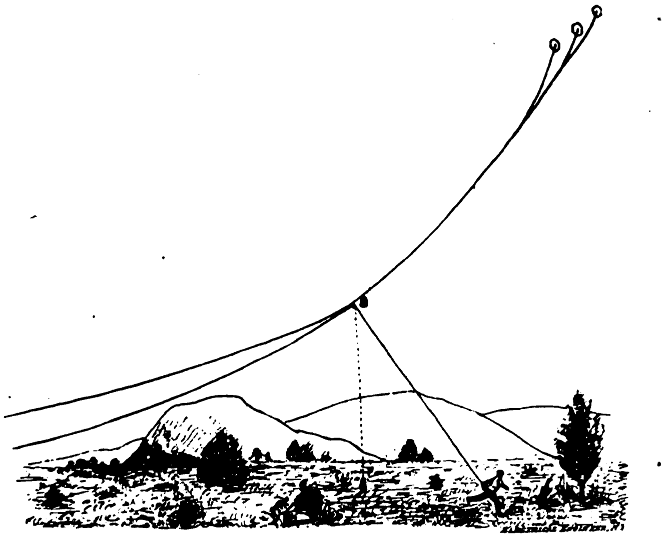

FIG. 2.—RUNNING THE KITE TELEPHONE LINE.

This is what really happened later, but on this first trial the friction of the wire against the harness rings through which it ran was so great that the lantern would not descend, and the wire broke, dashing the plummet lantern to pieces. I finally found an old pulley, which had been used for another purpose, about 3 inches in diameter, and this started off well, but the wire jammed in behind the wheel and again broke, causing the plummet lantern to fall about 400 feet upon a hard stone pavement in front of the residence of Col. C. W. Fuller. The lantern globe was smashed to atoms. However, I soon had another lantern in the air and this time succeeded. The wire with the plummet lantern, C, at the end of it reached the ground about 1,000 feet away, and Dr. Mitchell immediately grounded it with a brass grounding rod. He then came back to the base of the kite line where Henry L. Allen and I were managing the reels. He then ran a connecting bare wire from an iron pin driven into the earth through the two terminals of a small hand telephone without a bell attachment, to the wire which had been carried up the kite string and grounded at the other end. At the end where the kites were held the wire was not detached from the wire reel. Dr. Mitchell then told me to listen continuously at the telephone. I did so for some time, and heard nothing. I was about to give it up when I heard a faint clicking sound, which was the adjustment of the wires to the two poles of the telephone at the other end. Finally the first kite telephone message in the world came over the wire, sharp and clear: "Do you get me?" I answered "Yes. Good." After a few more words I looked at my watch and found it was 9:35 p. m.

I attribute the great clearness of the sound theoretically to the help from earth and atmospheric currents. I am now preparing to experiment with this midair wire to see if I can get results entirely without the magnets in the telephone at each end of the wire. I assume, of course, that the telephone will not work if merely grounded without magnetic currents already emanating from each telephone, unless a magnetic storm were in action, such as invades telegraph wires at rare intervals.

I have found strong atmospheric currents during four years of persistent experiment with atmospheric electricity from my kite wires, since October 8, 1892. Prof. Henry had long ago shown us that a lightning flash from a Leyden jar would magnetize steel needles. And why may not these persistent atmospheric currents, always present whenever my wire penetrates upward 600 feet, have sufficient force to operate an ear telephone?

Later, Dr. Mitchell connected a Morse sounder run by one cell to the telephone wire. The telegraph signals could be heard at the other end of the wire with great clearness. With a strong battery the message could have been sent from my kites by way of the main telegraph or cable system to San Francisco or around the world.

Such a wire, with a telephone instead of plummet lantern at the end of it could be dropped a mile away. We have just noticed that at Blue Hill Observatory, without telephoning or telegraphing, they paid out with the kites more than three miles of piano wire, on October 8, 1896. Telephone and telegraph communication could be opened in this way with a besieged garrison in time of war, as shown in Fig. 2.

THE TELEPHONE IN SOUTHERN NEW ENGLAND.

President Tyler, of the Southern New England Telephone Company has made a statement showing his institution to be in prosperous condition. They have 8,000 established stations and operate in 140 towns. The gross earnings for the fiscal year ending December 31 will be $550,000; the net earnings, $160,000.

The new stock has all been taken, and all but $97,000 of the $355,000 debenture bonds have been redeemed. Of the $630,000 in new stock issued, $630,000 was subscribed on or before the date set for closing the books.

President Tyler believes the company will earn $50,000 above the sum necessary to pay 6 per cent. dividends on the capital stock which is now $2,500,000.

MEXICAN AND SOUTH AMERICAN TELEGRAPHS.

The Central and South American Telegraph has declared a quarterly dividend of 1¾ per cent., payable January 6. Statement for year ending Dec. 31 approximates a surplus of $640,000. For three months ending Dec. 31, the following estimate of earnings is published: Gross receipts, $231,000; operating expenses, $79,000; net, $152,400; other income, $2,726; total, $155,126; dividend payable Jan. 6, $135,198; surplus, $19,928; previous surplus, $621,170; subscription to Guayaquil fire relief fund, $1,000; surplus Dec. 31, 1896, $640,000.

The Mexican Telegraph Company supplies the following statement of estimated earnings for the quarter ending Dec. 31, 1896: Gross earnings, $85,536; operating expenses, $17,000; net, $68,536; other income, $8,129; total, $76,665; dividend payable Jan. 13, $47,815; surplus, $28,850; previous surplus, $521,876; surplus, Dec. 31, 1896, $550,727.

RESCUE BY THE CABLE STEAMER "MINIA."

Capt. Samuel Trott, of the cable steamer Minia, had the good fortune on his recent trip for repair work off St. John's, N. F., to rescue the wrecked schooner Pansy and her crew of five. Heading for port before a heavy storm, Capt. Trott sighted the Pansy in distress about 60 miles out, picked her up, saved the lives of the exhausted crew, and towed her in without compensation. The St. Johns "Weekly News" says: "The conduct of Capt. Trott in this connection is worthy of the highest praise, and shows him to be an ideal mariner in the true sense of the word. His prompt and willing assistance was, under Heaven, the means of saving the lives of all on board the Pansy; and furthermore, not only did he save the lives of the captain and crew, but he actually towed in the vessel herself a distance of 60 miles, free of charge. From the homes of many a fisherman in Newfoundland will go up the prayer, "God bless the gallant Captain Trott."

MISCELLANEOUS

THE BEGINNINGS OF ELECTRICAL EXPORT TRADE.

BY A. A. KNUDSON.

(Electrical Engineer and Inventor.)

As the past decade may be considered as the beginning of our export trade in electrical goods (speaking broadly), it has occurred to me that some information on the subject of its past and present condition, as well as future possibilities may prove interesting.

To this end I have obtained statistics and consular reports from the Treasury and State Departments at Washington which can be relied upon as authentic, supplementing it by information obtained while residing and doing business in two of the countries named, viz., Canada and Mexico, and from other sources.

CANADA.

Of the English speaking foreign countries with whom we do business, Canada is our nearest neighbor, and it is but natural that there should be considerable trade between the two countries. The real beginning of electrical exports to Canada, however, was about ten years ago, commencing with the telephone and electric light, and later with electric railways. Incentive to increase further trade has been given at various times, such as the Electrical Exhibition at St. John, N. B., in 1889, with which I was connected; also a later exhibition of electrical goods held in Montreal in connection with the Electric Light Convention and by frequent periodical trips of representatives from the different firms in the United States. On account of the Canadian duties as well as high freights, several manufactories have been established in Canada for producing American electrical goods; and on this account our exports cannot expect to be as large as conditions might otherwise warrant. As the statistics show, however, that goods to the value of about $240,000 were exported last year (1895), it seems that Canada is not such a bad customer in this line of trade. Besides this, the above valuation does not include steam plants and accessories which generally go with electrical installations.

MEXICO.

Trade relations with Mexico have steadily increased during the past few years, with the exception of a slight falling off in 1892 and 1893. One cause of the increase of our exports in the last two years has been the war of freight rates by competing companies, resulting in merchants and others stocking up with goods in Mexico believing that the low rates would be only temporary. There has, however, been a legitimate demand for electrical goods, and the prospects are for the future that this demand will increase. The Federal District Railway of the City of Mexico, which was purchased about a year ago by an American and English syndicate, is now about ready, I am informed, to equip its 160 miles of track with electricity, which will without doubt be done with American apparatus. A large plant of American electrical goods will be shipped about the first of the year to the City of Jalapa, State of Vera Cruz, by the Stanley Electric Company, for a water power transmission to operate an electric railway and furnish light for some three or four towns, a portion of the plant, such as wire, etc., having already gone. Other schemes to develope the water power of different sections of the Republic by electrical long-distance are continually being broached and taken up, the incentive being the growing scarcity of wood for fuel and the high price of imported coal.

The abolishing of the interstate tax law of Mexico, which went into effect July 1, 1896, is considered by many to be quite an advantage to those engaged in shipping goods to Mexico. The Mexican Exposition often spoken of which has been postponed from time to time, is now, I am informed by the Mexican Consul, indefinitely postponed. It will probably materialize, however, some time in the next two years, and be generally useful.

In the City of Mexico there are several resident representatives of foreign firms. Of the electrical American firms may be mentioned the General Electric and Westinghouse, and of the wire firms Washburn & Moen, and John A. Roebling's Sons Co. The Pelton Water Wheel Company also does a large hydro-electric business. These firms, as well as others in different lines of business, recognize the importance of having resident agents on the ground in order to compete with other foreign houses who are generally well represented. The United States, however, has the advantage in one respect; it is the nearest country from which to obtain goods, and this is a great point in our favor. From my observations while a resident in Mexico, however, I think it quite probable that sooner or later Mexico will follow Canada in regard to manufacturing electrical goods within her own borders, just as other industries have been started there by English and Germans.

The low price of silver (operating as a protective tariff) and the low price of labor, are reasons, besides the cost of freight and duties, why manufacturing will probably be started in electrical lines in the near future in Mexico. A good deal of capital is being attracted to Mexico from both England and the United States, which is being invested in railways, mines, and electrical plants.

CHINA.

Our American Minister writing from Pekin under date of April 6, 1896, to the Department of State, Washington, says: The railroad development of China has attracted the attention of American financiers and builders of rolling stock and equipment. Many agents of American firms are now in this country awaiting the adoption of some definite plan by the Imperial Government. At least two combinations of American capitalists, represented here by agents, are prepared to build and equip from beginning to end any railroad system which China may desire. Later advices to the State Department report that one of the above syndicates, the American Trading Company, with offices at Shanghai, are bidding for the construction of a railway from Soochow to Chin Kiang, and for the building of an electric street railway in the foreign portion of Shanghai. Our minister also states that out of our total exports to China in 1895, amounting to upwards of $4,000,000, more than one-half was kerosene oil. This shows a desire for light at all events in that benighted country, and if the natives can be made to see the advantage of electricity as an illuminant over kerosene as other nations do, we should expect a substantial increase in our electrical exports, which now amount to practically nothing. The year 1895 showed only about $6,000 worth sent to China. Japan also took about $2,000,000 worth of kerosene oil in 1895, about the same amount as China.

JAPAN.

The total value of our distinctively electrical exports to Japan in 1895 appears to have been $24,000. The amount should have been much larger, and if the recent "missionary" visits of Japanese engineers mean anything, the amounts must increase greatly. Even during the past year, the Cramps have received orders for two Japanese men-of-war, and these will have electrical apparatus on them running up into large sums of money. Japan has always appreciated our electrical apparatus. Some of the first Edison installations went there. Some of the first Sprague motors are still in operation in Japan, and American telegraphs and telephones abound. If we will study the advice given by the American Consul at Osaka, there is no question about the increase of an electrical trade with friendly and progressive Japan.

GUATEMALA.

The American Consul in August last writes: In announcing the Central American Exposition which is to be held in Guatemala in 1897 the German boards of trade especially recommend manufacturers to exhibit tools and hardware of all kinds, as well as implements and machinery used on coffee and sugar plantations. Great efforts will be made for a good showing at that exposition. Banking and railroad building is conducted largely with German capital. The Consul also states: "There is every reason for our American manufacturers to be untiring in the solicitation of South and Central American trade. To be well represented at the coming fair with a full line of goods needed down there and by a person fully acquainted with the country, the people, and language, is only the beginning of the introduction of American goods." It may be said that the Germans have not captured all of the trade in Guatemala. Quite a business is being done with the South and Central American countries through commission houses in this city. One of our large electrical manufacturing firms is about shipping an important electrical plant for Guatemala, with a probability of more goods of the same kind going later on.

In regard to the Central American Exhibition, a copy of the rules and regulations, as well as other information, can be obtained by applying to the Guatemalan Consul General's Office, No. 4, Stone street, New York. Two articles of these rules we quote, as they may be of interest: "Article 2. The exhibition will be inaugurated on the 15th of March, 1897, and will close on the 15th of July, following. Article 8. On making application for space for exhibits the number, size, and nature of the objects must be stated. All applications must be made to the central committee before the 31st of August, 1896, but they will be received on and after the date of the publication of these regulations." I am informed by the Guatemalan Consul that up to this time not one application has been received for space from any of our electrical firms. It would seem, therefore, to be high time that intending exhibitors were looking into the matter.

VENEZUELA.

Mr. E. H. Plumacher, the consul at Maracaibo, in a report dated February, 1896, dwells on the friendly feeling towards this country, and emphasizes the importance of utilizing it in our trade relations. I can only echo his sentiments, for the enormous risks we have assumed in behalf of Venezuela should lead to reciprocity and better relationships. The Republic has been a fair buyer of electrical apparatus, and if cultivated would do better yet. I may note that this month a large shipment is being made by one of the leading electrical companies of dynamos and other apparatus for an electric lighting plant in one of the Venezuelan cities and other shipments are to follow.

PERU.

The American Consul writing under date of May 29, 1896, from Callao, forwards a copy and translation of an editorial from El Comercio of Lima, of May 16, discussing the increased trade with the United States. This paper attributes this to the direct steamship communication now existing between New York and the west coast of South America, by which material reductions in freights have been effected. The article also advocates the establishment of American steamship lines between San Francisco, Valparaiso and intermediate ports, and between New York and New Orleans and the Amazonian regions of Peru.

Under date of July 6, 1896, Mr. Alfred Solf, United States Consular Agent at Chiclayo, writes that an electric plant is wanted there and perhaps at other places in the neighborhood; and he desired to hear from American manufacturers, so that he may supply them with full particulars of the plant required.

SOUTH AFRICA.

The trade with the Transvaal and other countries of South Africa is principally in the hands of English and Germans. This would seem natural, as both England and Germany have colonies in that country. Our Consul, however, writes, under date of February, 1896, "that while the importation from non-British possessions has constantly increased, the greater part of this falls to the United States and Germany. The trade with the Transvaal passes more and more via Delagoa Bay, while German goods destined for other countries of South Africa go almost exclusively by way of Cape Town." Our Consul also says: "There is no doubt that Germany is becoming a formidable competitor in these markets which still depend largely on Europe and the United States to supply their wants." Our late Consul at Cape Town repeatedly called attention to the opportunities offered to develop our trade with South Africa. It is to-day, perhaps, the most promising field in existence for extending our export trade. A country possessing the enormous wealth which the Transvaal has revealed to the world must become a large buyer from the great exporting nations and continue so many years. South Africa to-day is full of American electrical apparatus for light, power and mining.

SUMMARY.

Statistics furnished me by the Treasury Department at Washington show approximately the amount of electrical goods exported to all countries during the past ten years. I say approximately, as electrical goods are not separately specified. Under the heading of "Instruments and Apparatus for Scientific purposes, including telegraph telephone, and other Electric," there were shipped goods as follows:

Year.	Value.	Year.	Value.
1887	$599,262	1892	1,388,117
1888	714,514	1893	1,345,621
1889	1,033,388	1894	1,534,277
1890	1,429,785	1895	1,912,771
1891	1,575,444	1896*	2,522,217

*When it ended (June 30, 1896.)

If we estimate that of these amounts 90 per cent. were for electrical goods, which would not be far off, a fair idea may be had of foreign trade in this line. It will be seen that with the exception of the years 1892 and 1893, which show a slight decrease, probably due to business depression, there has been a steady increase in our export trade. There has been a decided tendency in Europe to take our electrical apparatus, buy out the rights, and make it over there. We derive an increase from that source, which does not reveal itself in any tables of exports.

In conclusion it would seem that as we are likely soon to have another revision of our tariff law, it would be much to the advantage of electrical manufacturers if the former reciprocity treaty was re-established, not only with South American countries, but with Canada and perhaps Mexico as well; admitting our electrical goods free in countries wherever it is possible in exchange for certain goods to be admitted free of duty in this country.

It may be urged as an objection in the case of Mexico, that our electrical goods with a few exceptions are now admitted free. This is true, but when Mexico, like Canada, begins to manufacture (as already pointed out), then we may look for a prompt imposing of a protective duty in that country, and it may be wise to anticipate such action in advance.

In this connection, it may be of interest to give an idea as to what England is doing in the way of exporting electrical apparatus. To that end I give the value of electrical goods shipped during one week in each of the last two years: For week ending Nov. 17, 1895, £8,591; for week ending Nov. 17, 1896, £7,571. These goods were shipped to some 30 different ports in various parts of the world.

When it becomes more widely known abroad that the United States is shipping direct connected and other electric lighting and railway apparatus to England, we think this should have an important influence on our securing a larger share of the export trade than we now have for electrical goods.

THE IMPROVEMENT IN WIRE AND CABLE MANUFACTURE.

BY HENRY A. REED.

(Secy. and Treas. Bishop Gutta Percha Co.)

WITH the compliments of the season and hoping that many returns of your own natal day will find you prosperous and happy, I endeavor to comply with your request for a short synopsis of the development of the insulated wire industry during your fifteen years of effort to advance electrical industries.

There was little demand for high insulation in this country prior to 1882, except for subaqueous telegraph cables. I think that the only wires underground at that time were in a cable between the New York Stock Exchange and the Western Union main office. Those wires were insulated with gutta-percha, made into a cable and drawn through long logs bored like old-fashion wood pumps. Up to that date nearly all of the river cables had been made by the Bishop Gutta Percha Works, being insulated with gutta percha.

For several years prior to your first appearance, A. G. Day had been making a good quality of rubber insulated wires which were very generally used for leading from telegraph offices to the first pole, and for a very few inside cables. The inside wires were generally what are still known as "office wires," being insulated by cotton braid saturated with paraffine. Day had made a few river cables which were quite satisfactory, but people were better acquainted with gutta percha and bought it.

The same conditions which at about this period (1882) seemed to make room for another electrical journal created a demand not only for more insulated wire but for greater variety, and higher average quality. The telephone, which had been publicly exhibited less than six years prior to your birth and was for some time considered by the public only a clever toy, had shown its capabilities to a large extent and business men felt that they must use it or be behind the age. To explain or even to mention the various experimental cables made to meet only partially understood requirements of this new-comer, would extend this article far beyond reasonable limits, but I will say that the man or woman who first suggested "twisted pairs" should have been well rewarded here and given a free pass to telephonists' heaven.

Up to 1882 electric lighting had been almost entirely by arc lamps with wires on poles. I believe that the first underwriters wire was made by Mr. W. W. Marks, the first superintendent of the Bishop Works. He covered the wires with three successive braids of heavy cotton, each coat thoroughly saturated with white lead paint, which had lead in it. Each successive coat was compressed and the last braid had two or three coats. Some of this first wire is still doing duty and may continue for several years, but somebody discovered that dirt was cheaper than lead and very soon the so-called underwriter's wire was correctly named undertaker's wire. People lost faith in paint and went for rubber with a rush.

The rubber field was inviting, and made more so by the introduction of steam pipes in the streets which rendered gutta percha useless in their vicinity. Hotchkiss, the enterprising agent of Kerite, made a good deal of hay in the shine of electricity, but soon Grimshaw came from England with his patent hook well baited. Brother Gallaher got hooked, but being amphibious he managed to live after being landed, and soon learned to make good rubber insulation which he called "Grimshaw" in memory of the hook, although it was not made à la Grimshaw. He formed the New York Insulated Wire Company in 1884. He has done a great deal of good work and still remains in the hottest of the fight, showing few scars.

A little later "okonite" insulation came, claiming a mysterious origin and a more mysterious composition. Both origin and compound seemed dark, and they have always chosen dark backgrounds; but their stuff had virtue in it, and big pushers behind it and for many years, especially in the West, the cry was, "If ye blows for Candee, ye drinks mit me."

About the time that Gallaher and Candee were getting into shape Dr. Habirshaw and the intrepid Requa were pulling together trying hard to make something that was cheap and good. They seem to have got discouraged on the lines they were pursuing and struck rubber. The concussion was so heavy and the rebound so great that they went in different directions, never to meet again; but they both got into the swim. Habirshaw called his company "The Gutta Percha and India Rubber," which is half true, and that is more than can be said of most rubber claims. His "red-core" insulation is rightly held in high esteem and he is one of the ablest men in the business. Requa pulled a strong oar till he got into "Safety," and is now the highest roller in the lot.

Up to 1885 the Bishop Company's motto was "Nothing like gutta percha," and there are still a few people who don't like "Bishop wire" because it softens in the sun.

Mr. Bishop having died July 4, 1872, on the same day as ex-President Adams, the business was conducted by Superintendent Marks for the widow until her death in 1881, and for her executor until 1885, and was therefore continued in the old tracks until the latter year, when the present company was organized, and no important changes were made in the work until 1887, when the present manager was given charge.

Having been in telegraphy for 16 years and for several years engaged as expert in the "Simpson-Colgate Insulation" patent suits, he was supposed to be posted on insulation in general. He also went for rubber, selecting as the best type then extant, the celebrated "Hooper's white core" which had done good service for many years in telegraph work in England and India, and had stood satisfactorily the fogs of the former and the burning sun of the latter. While using rubber, pure and compounded, for electric light work and all places exposed to great heat, this company still recommends gutta percha for submarine cables and claims that for flexible cords its Balata" is up top. It still nails to its flag the motto. "Bishop Means Best," and claims to make no second grades.

Besides the five companies mentioned above, there are at present eleven more, some being large and strong, sixteen in all, making rubber insulated wire.

Where $200,000 would probably have paid the cost of all high insulated wire and cables made in this country in 1882, the sales last year are estimated at about $5,000,000. A very large portion of this was for underground work for electric light and for electric railway feeders.

I believe that the first cables to successfully carry high tension currents underground were made by the Bishop Company and placed in conduits in 125th street and in Broadway and Fourteenth street, New York, in the spring of 1888, and that they are still working. They were insulated with three coats of rubber; the one next the wire containing no sulphur; the compound of the other three coats contained 3 per cent sulphur for flexible vulcanization. The rubber was protected by rubber tape and encased with lead. Nearly all of the successful cables in use to-day for high voltages are similar in construction. The Standard Underground Cable Company, the Western Electric Company, and some others, have made for several years large quantities of telegraph, telephone and signal cables by saturating the cotton wound wires with hot paraffine, bittite, rosin, wax or pitchy compounds encased in lead. These answer well for low tension currents as long as the lead holds.

Paper cables with rosin oil as an insulator have been made by several parties and, being cheap with high insulation, are much used; but they also depend upon the lead to keep their feet dry. The best working telephone cable for underground work is insulated by dry paper wound around the wire in such manner as to leave room for as much dry air as possible. Telephone currents stick pretty close to their tracks, not being coaxed off by poor conductors, but want some room for flourishes, which gutta percha and rubber does not allow them.

One of the thorns in the sides of insulated wire men has been the architect who knows nothing of electricity and the electrical engineer who knows less about insulated wires. This has been largely remedied recently by certain competent engineers, who have made a special study of insulation, and now our main trouble is the dirt craze, which should have the title of the exploded silver craze, "16 to 1."

Pure rubber is a higher insulator than gutta percha, but not so easily applied to the wire. Fortunately it is able to carry a large amount of adulterant which renders it more tractable and much cheaper. I believe that a large portion of the people who are insulating wire with rubber compounds, can make good stuff and would do so if they could get paid for it, but when people who want wire invariably buy that which they get at lowest price and the cost is regulated by the proportion of adulterant costing three cents per lb., and of rubber costing over a dollar per pound, the temptation to use sufficient rubber for good results is not strong.

PATENTS AND ELECTRICAL INVENTIONS.

BY HENRY C. TOWNSEND.

(Patent Lawyer, formerly Chief Examiner, Class Electricity, U. S. Patent Office.)

TWENTY years ago under the stimulus of the achievements of Pacinotti, Gramme, Siemens and others in developing electric energy from mechanical power, there began the new age of progress in electrical inventions and it was then the privilege of the writer to be a spectator behind the scenes of the inception and early rapid growth of the art commercially, as evidenced by the numerous applications for patent filed in the United States Patent Office by Edison, Thomson, Brush, Weston and others. About the same time there sprung into being the new art of telephony.

Up to that period the efforts of inventors, exerted through the forty or more previous years, had resulted in the accumulation of a host of patents in this and other countries touching almost without exception every branch of the art to which the attention of inventors has since been directed, and this despite the fact that commercially little had been done in any of them, barring perhaps that of telegraphy. To the public generally the whole subject was an unopened book. But little litigation had taken place and the courts generally were unfamiliar with the topic.

At even a later period and not many years ago, it was necessary for the writer, as attorney for inventors, to contend frequently and strenuously against the requirement of the Patent Office Examiners that any claim for a system of circuits or for an apparatus involving a switch or circuit controlling device as a part thereof, should specify in all its details the mechanical form or construction of that switch. The expression, for instance, "shunting switch," was not satisfactory, but it was necessary in the view of the examiner to specify a lever (if a lever were used) contacts, connections, etc., in detail, with the result of limiting the claim, detracting from its clearness and confusing in the mind of the public the true nature of the invention. The day of such requirements may safely be said to have passed.

But inventors have suffered not alone in the Patent Office from misguided views as to the meaning and scope of claims upon electrical apparatus. Some ten years ago the Supreme Court of the United States held that a new system of railway signaling, which involved as a part or element a means for closing a circuit by the passage of the train, was not infringed by a system identical in all other respects, excepting as to the circuit closing devices, because the patentee described and showed, as a circuit closing means, a section of insulated rails, while the infringer used a circuit closer mechanically actuated, although as a matter of fact the two devices had been known in the art for years as equivalents of one another and the specification stated that the patentee did not limit himself to the particular devices described for closing the electric circuit at points from which the signal was to be operated.

The decision so outraged the sense of justice of inventors and electricians pretending to any large knowledge of the art of electricity and its applications, that the writer may be pardoned for thus speaking of it, even at the risk of seeming to be guilty of lack of the proper respect which a member of the bar should feel for the opinion of our highest court of justice.

It is not many years since a valuable patent, lying at the foundations of the present systems of electrical distribution, was emasculated through an unskillfully drawn disclaimer, intended by the patentee as a simple declaration that he did not claim to have invented one of the ways in which his invention had been applied, but interpreted by the court as a surrender of his right to hold the user of the invention in that particular way as an infringer, an interpretation only to be tolerated on the theory that the court's knowledge of the nature of electricity was so crude as to incapacitate it for interpreting the patent. That was quite early in the period when active litigation over electrical patents began. The later history of litigated patents seems to indicate a profounder or a more familiar acquaintance with the subject generally on the part of our courts and counsel. At any rate, the time has gone by for counsel to experience the enervating dread that in the critical stage of his argument the court will interrupt to ask "Mr. ———, What is electricity?"

The early years of the last decade were halcyon days for the professional electrical inventor. The tyros with a smattering of knowledge of the subject of electricity, supplemented in many cases by only a little higher order of knowledge of mechanics, rushed into the new field of activity opened up by the commercial introduction of incandescent and arc lighting and telephoning. Companies were organized upon patents for inventions based upon most trivial variations of machines or apparatus that had been previously known for years. Some who read these lines may recall the formation in those days of a company with hundreds of thousands of dollars paid in capital upon the strength of a patent for a dynamo machine whose armature had been improved by using four coils instead of the three which had been previously known and patented to a prior inventor.

The telephone art saw many similar instances of capital embarked on the strength of patents for apparently endless variations in arrangements of telephone contacts and mounting of the same, but these enterprises fell into early decay through the complete enforcement of the Bell patent.

But the same period has seen also many enterprises, founded upon meritorious inventions, predoomed to failure because not addressed to a prevailing need or because involving too wide a departure from methods and arts then prevailing. Thus, early in the eighties, much effort, research and capital was expended in systems for telegraphing to moving trains, for distributing correct time and for telegraphing by what is known as the multiple synchronous system.

The lesson to be drawn by the electrical inventor from the failures experienced in these and other lines is perhaps that he should confine himself to inventing along the lines of commercial progress instead of venturing into new and untried fields. This is, however, a course which, had it been sordidly followed, would hardly have resulted in the evolution of a telephone, a phonograph or any of the other marked advances in the art which have sprung from the assiduous efforts of electrical inventors.

However, by closely following the rule the inventor may not, as one of them has put it, experience too frequently those periods "of inventive activity but financial depression" to which unfortunately some of them are subject.

It is to be perhaps regretted, from the standpoint of the inventor, that the fierce war prevailing not many years since between the advocates of the high tension and low tension systems of distribution has come to an end. We no longer hear the high tension system stigmatized as a "cheap makeshift only, possessing no element of permanency," and its promoters branded as "apostles of parsimony."

Nor have electrical inventors generally to fear that their occupation will decay under assaults or appeals such as that which illumined the pages of a certain anonymous, red pamphlet attributed to unfriendly "gas interests" and which was thus worded: "Our lives and those of our families are at risk and it behooves every citizen to look to it that we are not to have our very hearthstones caged in by a network composed of an element antagonistic to both life and property, although presented to us in the guise of a boon and a light to our way."

Nor need the progress of invention stop because of any doubts engendered by the sage observation, true perhaps now as then, contained in the familiar red "Warning from the Edison Electric Light Company" of 1887, to the effect that "A consolidation of ownership of patents which are of themselves intrinsically worthless, does not add to their legal status or value nor to their commercial value."

It is a genuine subject for regret that so few electrical patents have been sustained and that so much time is required in determining their validity. Even now the end of litigation begun in 1886 upon some electrical patents of prime importance has not been reached.

Nothing can, however, more effectually discredit the whole patent system and impair the value of patents to inventors than the frequent overthrow of them in the courts upon the ground that an anticipation of the alleged invention is found in prior patents or publications. It is a reproach to the system, as at present administered, that so many electrical patents should suffer in this way, and it behooves electrical inventors as a class to devote their energies to seeing that the Patent Office is better equipped for its work of examination. The value of the patent system in promoting the progress of the arts and sciences is unquestionable and our system as organized should not be discredited, but its shortcomings should be supplied, or, if it be not capable of successful operation on the present lines, it should be radically amended.

ELECTRICAL MEASUREMENTS.

BY PROF. W. A. ANTHONY.

REFINEMENT in electrical measurements may be said to have begun with the manufacture of submarine cables for telegraphic transmission, and it reached a high degree of development in 1855 to 1860, under the pressure of the Atlantic cable work. In 1861 a committee upon electrical units and standards were appointed by the British Association. This committee went to the root of the whole matter, proposed a consistent system of units, made experiments to establish their values, and prepared physical standards by which the values determined were embodied in a form for comparison and duplication.

Down to 1880 the importance in the arts of electrical measurements was mainly in connection with telegraph lines and cables. The latter, especially, required instruments of great delicacy and precision, because of the extremely small currents employed upon them. The marvelously delicate galvanometer and the quadrant electrometer of Sir William Thomson were an outcome of the requirements imposed by the development of telepraph lines. The measurements to be made were almost wholly resistances of conductors and insulation, the electromotive forces of battery cells, and capacities.

This was the condition of things in 1880, when the development of the dynamo electric machine and of electric lighting systems, created a demand for electrical measurements of a totally different character, and under very different conditions. On telegraph lines the measurement of current was of little consequence. The electrical energy consumed was small and its amount was not taken into consideration. Very little attention was paid, therefore, to the efficiency of apparatus. It was of far more importance to save labor and to secure unanimity from interruptions and delays in the service than to save in the electrical energy employed. Hence there was little call for measurement of currents.

With the development of electric lighting systems, however, where the energy employed was expressed in hundreds and thousands of horse-powers, the measurement of currents and potentials came to be of highest importance. Measurement of resistance while still of service, passed into the background. The currents to be measured were of magnitudes before unheard of. For the measurement of such currents special instruments had to be devised, as nothing previously constructed would serve the purpose. So with electromotive forces; they had previously been expressed in terms of the number of battery cells employed, or were measured by balancing them against cells of known e. m. f. Such means of measurement were, to say the least, very inconvenent for the measurement of electromotive forces of dynamo machines, or the differences of potential at different places in the circuit. From 1880 on, appeared a number of special instruments intended to meet the requirements imposed by the new conditions. The writer remembers using in 1881 the dynamometer form of current measurer of Siemens and Halske and a voltmeter of the same firm, consisting of a bell magnet in a coil of fine wire. In both these, electrical forces were balanced by a spiral spring by which the movable member was brought back to zero before reading. In the same year the instruments of Deprez and Carpentier were on the market. Following quickly after these were the graded galvanometers of Sir William Thomson and the well-known instruments of Ayrton and Perry. Then came the Thomson balances where the mutual action between currents was opposed directly by the force of gravity; and finally were brought out the instruments of Edward Weston, in which the force of a current in an artificial magnetic field is opposed by the force of a flat spiral spring.

Hosts of other instruments more or less well known have appeared and are on the market.

The measurement of heavy currents has presented and still presents grave difficulties. It is almost always done by dividing the current into two parts in a given proportion and measuring the smaller. What amounts to the same thing, the potential difference between two points upon a conductor carrying the current, is measured by means of a delicate voltmeter. The resistance between the two points being known the current flowing may be determined. Or the resistances, and, therefore, the subdivision of the current between them, may be entirely unknown, and the instrument as a whole calibrated by reference to known standards.

At the present time current measuring instruments are standardized by measuring a difference of potential and a resistance, or by reference to a silver or copper voltameter.

With such means at hand for standardizing current measuring instruments we are almost forgetting the true definition of the unit current and coming to look upon it as derived from the units of resistance and potential instead of being itself the foundation upon which the others rest, and from which they must at first have been derived. The true definition of the unit current is: It is that current which, flowing in a thin conductor of unit length forming an arc of a circle of unit radius, produces at the center of that circle a unit magnetic field. Or, what amounts to the same thing, and puts the definition in a form such that measurements in terms of the unit may be exactly realized in a n apparatus: The unit current is that current which, flowing in a thin conductor forming a complete circle of unit radius, produces at the center of that circle a magnetic field whose strength is 2π.

The tangent galvanometer, if of such size that its dimensions may be accurately measured, furnishes the means of exactly measuring a current in terms of the unit as above defined. So would also an instrument constructed upon the principle of the Thomson balance. Such a measurement of current is an absolute measurement, depending upon no arbitrarily chosen or imperfectly determined units, but resting only upon the fundamental units of length, mass, and time.

It was necessary in effect to make such a measurement before the true value of the volt or of the ohm could be determined. It was such a measurement that the British Association committee attempted in 1864 for the purpose of fixing the value of the ohm. But, as we now know, their determination was in error by more than one per cent. In 1880 the true value was still unsettled, although it was known that the standards in existence were to some extent in error.

It was this that led the writer to project the great tangent galvanometer of the Cornell University which was not, however, finally completed until some time in 1885. This instrument was so designed that its dimensions could be accurately determined. It contained within itself the means of determining the strength of the earth's magnetic field with which the field produced by the current was compared. The coils were such that current all the way from a fraction of an ampere to a hundred amperes or more could be directly measured. Its needle was quite dead beat and readings could be rapidly taken.

But such an instrument would have been worthless for general use. It was necessary to locate it at a distance from all other buildings, where the magnetic field could not be varied by any accidental or erratic causes. Probably no place could be found for such an instrument within the limits of a large city. Its special use was in standardizing other instruments. Although it could be and was used for measuring directly the currents in such tests as were made at the Cornell laboratories.

But the need for going back to first principles in the measurement of currents has now passed. By means of numerous absolute determinations the values of the several units have become definitely fixed and physical representatives or embodiments of those units have been devised, and it is now possible by reference to standard resistances and Clark cells to measure currents to an accuracy of one-tenth of one per cent., and then check the result by reference to a silver voltameter.

But it is not alone the methods of measurement that have undergone a change. The currents to be measured have increased enormously in the last fifteen years. Currents reckoned in thousands of amperes are in use now where tens of amperes were in use fifteen years ago. In resistance measurements also the quantities to be measured have undergone great changes. Formerly it was telegraph lines and cables having resistances of hundreds and thousands of ohms that were the main subjects of measurement. Now conductors and armatures of dynamo machines having resistances reckoned in millionths of an ohm must be measured as well. For the measurement of such small resistances the old bridge and resistance set is useless and methods that before were hardly known except as possibilities had to be brought into use. The fall of potential method finds to-day perhaps almost as extensive employment as did the bridge and rheostat fifteen years ago.

But it is not alone in the measurement of the old quantities —current, potential, and resistance, that changes have taken place. With the development of the dynamo machine other quantities have assumed an importance that they had not before possessed.

The quality of iron that goes into a dynamo is of prime importance, and yet it is something about which fifteen years ago, very little was known. Now special instruments are at hand for the measurement of magnetic permeabilities and in every dynamo manufactory samples of the iron and steel employed are tested.

Again the employment of alternating currents in lighting and power tranmission has brought to the front another series of measurements which before had found very few applications. Now, induction constants are becoming as familiar as resistances. Henrys are as important as ohms. Phase difference, too, must be considered and "angle of lag" has become a part of the vocabulary of the ordinary wireman who has had to do with the installation of alternating current apparatus. All this was almost unknown even ten years ago, except to readers of abstruse mathematical treatises upon electricity.

Of all these various advances in the art of electrical measurements, perhaps the most important is the final establishment to a degree of precision sufficient for all the purposes of the industrial arts, of the values of what may be considered the fundamental electrical units, the ampere, the volt, and the ohm, and the definition of the physical representatives of these values in a form that it is possible to reproduce without resorting to an absolute determination.

THE ELECTRICAL SUPPLY HOUSE PAST AND PRESENT.

BY W. H. McKINLOCK.

(President, Metropolitan Electric Co.)

It is a pleasurable task that I set myself to perform, at your invitation, coupled with feelings of, I trust, pardonable pride, to officiate in any capacity at the Crystal Celebration of "The Oldest Electrical Paper in America."

The electrical supply business at the period your paper first saw the light (electric) was unknown to the commercial world. It is true there were those who manufactured and dealt in electrical apparatus and supplied such articles as telegraph instruments, medical batteries, fire alarm apparatus, etc., but the electrical supply house, pure and simple (the word "simple" here is used as a figure of speech only, for it is a matter of common knowledge that the electrical supply business is considered the most difficult to conduct of any branch of the great industry, centralizing, as it does, the mechanical, technical and commercial), did not come until the telephone and electric light were fully developed; or, perhaps it would be more nearly true to say the supply business grew out of the development of the telephone and electric light, and is a necessary adjunct thereto.

The West is peculiarly adapted for the supply business, and that is where it has had its greatest growth and enlargement. As the young science began to be recognized in the industrial arena, factories sprung up in the East, where labor and capital are cheaper, to give it form and facilitate its progress. This left the great West as a distributing point for the finished product, and Chicago as the chief city and center of the new enterprise. Supply houses were started in a small way as experiments, and were found to be profitable. Electric light plants, electric railways, telegraph and telephone companies found it more convenient and profitable to order from one house all the little parts necessary to maintain and enlarge with, than to order from a hundred different places, thus reducing the labor of shipments, expense in carriage charges, account keeping and kindred annoyances. And just here comes in the difficulties of the supply man. He must keep in advance, or at least abreast, of the development of the science. He must be able to tell the difference between a German silver contact point and a platinum contact point upon a bell that may sell for a quarter, or to give a scientific test of the corpuscles of the blood by means of the X-ray. A man comes into your place of business from some small town, where he is considered all-wise, for the purpose of buying a plant outright and putting it up himself. It may be a small plant, to be sure, but as he knows very little about applied electricity, you must be able to show him just what he wants, and by your assisting him in pointing out the necessary carrying capacity of the dynamo, the size and kind of wire, the style of lamps he should have, you can make a fair sale; but, alas! such opportunities are rare, indeed, these days.

The supply business, however, has come to stay, and is a necessity to the station manager, and to the whole people at large (for who does not use electricity in some form nowadays?) as the butcher, baker and candle-stick maker is to the housewife. There is a saying that competition is the life of trade. It has almost been the death of trade in the supply business. As between the supply house and manufacturers, and supply house and supply house, the former is perhaps the more disastrous, for the supply houses in competition with each other are upon an equal footing, to an extent—the best man wins. But when the manufacturer endeavors to compete with his own products in the hands of a supply house, there can be no escape from ruinous prices, distrust of customers, sharp practices, and a lower morale of the business, sure to end in disaster for either or both. This method has been pursued from time to time by some manufacturers on account of an unwillingness on their part to accord the supply houses a position in the field. Many of the larger manufacturers, however, have found it to their advantage to employ the supply houses in the West to introduce their goods and act for them as their representatives.

A supply house from the very nature of the business must not be prejudiced against any article of merit, and should furnish anything its customer may order, if he can do so without loss to himself, and his customer's trade is desirable. One instance in point: A customer a thousand miles away ordered, among other things, 10 lbs. of Wienerwurst sausage, and because Wienerwurst was sausage, and, strictly speaking, not an electrical product, should we not furnish it? We certainly should, and did, and had the everlasting confidence and trade of this same electrician.

The capital necessary to run successfully a first-class supply house is no mean consideration, for where a large number of accounts are made, a major balance of them are always open on your ledger, thus wrapping up a large portion of your surplus. Then, too, the varied line of goods necessary, and the large amounts of each required to fill an order, or several of the same kind, promptly (for promptness and dispatch are cardinal points to be well regarded) make up a considerable portion of your sinews of war. The building and putting into the hands of probable or even possible buyers of your wares, of catalogues, which in theselves are the sine qua non of things electrical, is an expense which must be taken from your capital, and regarded as an investment to be provided against out of the profits later on.

It is needless for me to say that it is impossible to visit all probable purchasers once a year. Some you can visit oftener, and to those never, you must furnish cuts and descriptive explanations of the uses of the goods you have to sell.

In a word, the supply man must be alert to everything that is about to be put on the market, and often suggest to the inventor things needful, and be able to explain to his customer all about it, and the whys and wherefores thereof. His position enables him to be beforehand with new inventions, seeking remunerative reward, for if he be wide awake, he is sought after as well as seeking.

MUNICIPAL PLANT RESULTS AT HAMILTON, O.

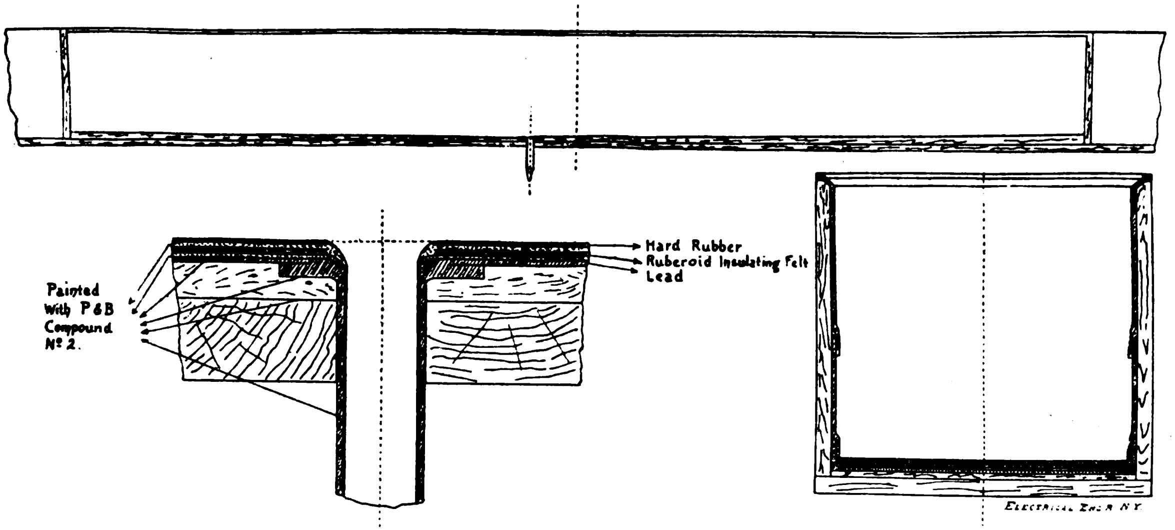
The trustees of the Hamilton gas works say they will close the electric light plant and discontinue street lighting after January 1, for the want of money to operate the plant. The city is already out an amount stated as high as $50,000 and the people are slow to put their hands in their pockets for $50,000 more.

BUFFALO is to celebrate the arrival of Niagara power within its limits with an "electrical dinner" at the Ellicott Club on January 12. A representative gathering is expected.

LINING FOR STORAGE BATTERY COMPARTMENTS.

AMONG the European cities in which accumulators are used for the propulsion of street cars is Hanover, Germany. In this instance the batteries are drawn upon while the cars are within certain city limits, while beyond these the trolley system is employed.

Much trouble has been experienced in the past from the action of the acid on the compartment in which the batteries are carried and various devices had been employed to overcome it, but without success, until the application of the P. & B. insulating compounds and Ruberoid felt removed all difficulties. As the use of storage batteries for this and other purposes is rapidly increasing it will be of interest to show in just what manner the work of making the batteries acid tight and insulating was carried out. This is detailed in the following communication from the Hanover Street Railway Company to Messrs. Allut Noodt & Meyer, Hamburg, Germany, who represent the Standard Paint Co., in Germany.



FIGS. 1, 2 AND 3.—METHOD OF MAKING STORAGE BATTERY COMPARTMENTS INSULATING AND ACID PROOF.

Great care is to be taken first, that the space shall not contain any metal screws, nails or like articles penetrating into it from the running gear or the body of the car. As this was the case with the car boxes in use thus far we have decided to put into our accumulator spaces a second bottom to which we will refer hereafter. It is necessary to examine all the spaces to be covered and to see that they are completely dry. This done we commence work by cleaning the walls of all dirt, oil-spots, etc. We thereupon fit very accurately the before-mentioned second bottom and finish it with an opening for the acid drain pipe. See Fig. 1.

We employed formerly two drain pipes which were fitted at both ends of the accumulator box. In order to avoid seams for the lead cases thereafter to be fitted, we employ now for each box but one drain pipe which, corresponding with the situation of the iron part of the running gear is removed 130 mm. from the center of the accumulator box. In order to promote the easy drainage of the acid, we fit the second bottom at an incline of 1 to 110, shown in section in Fig. 2.

After being fitted this bottom is taken out again in order that the lower bottom be given a coating of P. & B. composition No. 2, diluted with the diluter furnished. Thereupon the second bottom is well painted on the lower surface with the diluted P. & B. and pressed promptly to the lower bottom. In order to obtain a good union, we lay heavy iron pieces uniformly over the surface and let them rest there for three to four hours. We thereupon paint all the joints, flaws and holes of the box with diluted P. & B. composition very carefully and fill them up afterwards with the thicker P. & B. composition. We then give a good coating to the bottom as well as the side walls, the latter to a height of 100 mm. with the diluted P. & B. composition; after this coat follows a second coat with the undiluted material and a lead box is inserted promptly which in order to effect a perfect union is to be weighted down and the sides of which are to be smoothed off.

This lead box is made of sheets of 1.5 mm. thickness. The height of its sides is 100 mm. The edges are soldered only after the box is fitted in its place. The previously introduced drainage pipe is also to be soldered with lead. After an intermission of about 12 hours for the purpose of the permanent union of the lead coating all surfaces of the box are carefully painted with diluted P. & B. composition, and after they are again dried they are painted twice more with the undiluted P. & B. composition. The bottom is to receive a coat of special thickness and another intermission of about 15 hours is to intervene.

Then we commence with the pasting in of the P. & B. Ruberoid insulating felt ½ ply. The covering for the lower part of the box should be cut out of one piece. The width of the felt is sufficient to employ it bent over for the lining of the entire length. The sides are also to be put on in one piece. On all portions remaining uncovered the felt is put on so as to overlap the lower sheet. The upper end is lapped over and fastened by nailing a wood moulding over it; see Fig. 3.

Before inserting the felt the same is covered strongly with undiluted P. & B. composition and the inserted ruberoid felt is pressed with sticks to the bottom and sides until it adheres firmly in all places.

At the four corners of the bottom, suitable slips of uncut ruberoid are bent and pasted into place. All about the edges of the bottom there is to be fitted a strip of the ruberoid felt. After a few hours the whole is covered with a double coating of undiluted P. & B. composition. We then pour over the bottom evenly a quantity of the thick P. & B. composition about 2 mm. thick. After this is dry a hard rubber plate of 1 mm. thickness is covered over it. For this purpose the edges of this rubber plate are coated heavily to the width of about 50 mm. If the rubber plate is corrugated all the tops of the corrugations must be painted.

In order to obtain a good adherence all edges and walls or sides have to be covered with wooden laths held down by heavy weights.

If there should be any open joints or any openings on the edges of the plate they should be thoroughly and carefully filled with the thick P. & B. composition. If the work is done carefully and cleanly this coating will keep a very long time and need very few repairs. We cannot recommend at all the coating with rubber, as, notwithstanding our having used the very best material of rubber, the results we had were the very worst that could be imagined.

We are confident that the lining we employ will answer all expectations in regard to insulation and acid resistance.

ELECTRICAL ENGINEERING EDUCATION.

BY FRANCIS B. CROCKER.

(Professor of Electrical Engineering, Columbia University, N. Y.)

THE changes which have been wrought in electrical engineering education since The Electrical Engineer was established in 1882, are even greater than those that have occurred in the art itself, in spite of its remarkable progress. At that time only two of the five great branches of electrical engineering, telegraphy and telephony can be said to have been established on anything like their present basis, and even these have been enormously developed since that time. Electro-metallurgy, although the oldest practical application, was of little importance; in fact, only within the last two or three years can it be said to have fulfilled even a part of the great results which have long been expected from it. But there is every reason to believe that the ratio of its progress in the future will be greater than that of any of the other departments of electrical enterprise. These statements apply not only to electro-metallurgy specifically, but also to primary and secondary batteries and to electro-chemical work, which may all be included under the same general head. In 1882, the scientific as well as popular mind was still filled with the enthusiasm for the storage battery which was aroused by the announcement of Faure's inventions of the preceding year. In this case also the hopes were not realized until within a few years. Electric lighting was then well started on its successful career. The arc systems of Brush, Weston and Thomson & Houston had been introduced and accepted. The incandescent system of Edison had just been established upon a commercial basis. But the size of the plants, and the number of lamps in actual use were very small figures compared with those of the present day. The alternating current system which now constitutes such an important part of electric lighting, was not brought out for several years after that time. The other great branch, electric power, had its entire period of development since the founding of this journal. At the Munich Electrical Exhibition of 1882, Deprez demonstrated to the world the principles of long-distance transmission of power, for which he deserves far more credit than is usually given to him. He not only led the way in concrete results, but he brought out, or at least made clear, certain principles of the electric motor, including the relation between counter and direct electromotive forces and resistance, that were very imperfectly understood at that time. It was not, however, until about 1886 that the electric motor began to be generally used, and its application to street car propulsion was not successful for several years after that. It is therefore substantially correct to say that electric power, including its transmission and distribution, has started and reached its present position in the first rank of human agencies, during this short span of fifteen years.

This rough sketch of the advances made in applying electricity, represent in a general way the changes that have taken place in electrical engineering education, the latter being naturally and properly moulded by the former. Nevertheless, it has had a history of its own, due to its own particular conditions; and furthermore, it can be fairly claimed, as stated in the opening sentence, that its progress has been even greater than that of the arts and sciences with which it has to deal. In 1882 we have seen that in some directions, at least, considerable progress had already been made in electrical engineering, but at that time the corresponding education did not exist. The nearest approach to it were the mechanical engineering courses given in several colleges and technical schools in this country. These supplied the young engineer with the general training which is so important, and the special knowledge of mechanical principles and applications, including steam engineering, which are also needed; but they failed to give a sufficient knowledge of electrical principles and appliances. The amount of electrical instruction was very small, that is, the number of hours devoted to it, and in most cases it was not well suited to the new conditions. For example, frictional electricity, primary batteries and permanent magnetism were practically the only subjects considered. While the same fundamental principles apply to all electrical and magnetic phenomena, there is little or no direct application of these antique subjects to most of the modern uses of electricity. The writer believes in teaching electricity and magnetism according to their historical development, because that is the natural order in which the facts are acquired by the human mind; but great care should be taken to prevent the student from getting an exaggerated idea of the importance of static electricity, and in all cases instruction in dynamic or current electricity should immediately follow, and the proper relation between, and the relative importance of, the two should be clearly pointed out. Every electrical engineer has probably observed that the old-fashioned methods of teaching electricity in the colleges and schools often gives wrong notions to non-electrical persons, even though they may be otherwise well educated. The most familiar of these erroneous impressions is the idea that the dynamo works on the same principle as the frictional electrical machine which was the most prominent feature of the scientific apparatus of almost all colleges and schools, the recollection of which was made particularly strong and lasting by the "shock" usually administered to the members of the class. It is indeed a question whether the modern uses of electricity would not have been better and more quickly understood by the public if it had had no preconceived and self-satisfied ideas concerning electrical matters.

Nearly all of the men who entered the electrical profession up to 1882 and for several years after that, acquired most of their electrical knowledge by experience and self-instruction. At that time this journal was called "The Electrician," and it was also customary for men engaged in electrical work to be designated by the same name. The difference in title represents an actual difference in fact, the engineering side not having been recognized and developed at that time. Electricians as a body were then made up chiefly of those who were or had been engaged in telegraphy, the only branch that had been established for any length of time and the sole field for obtaining practical experience. In addition to these telegraph electricians there were a certain number of scientific men, usually professors of physics or chemistry in the colleges of this and other countries. These men naturally turned their attention more and more to this subject, which was in the line of their work and appealed to them on account of its intrinsic interest and growing importance. They contributed to it scientific methods, notably definiteness in terms and exactness in measurements which are characteristic of electrical engineering and make it an example for the other branches of applied sciences to follow. The ranks of electricians were also recruited from those having an inborn aptitude for the subject, and who entered the profession as a duck takes to water. In many cases these volunteers had had little or no preparation, but their natural taste, amounting in some instances to genius, was equivalent to or far better than mere education, particularly in those early pioneer days. These three classes constituted probably nine-tenths of the then small body of electricians, including its most eminent members as well as those of less prominence.

The enormous extension of the electrical industry soon created a demand much larger than could be supplied from the sources then existing. A demand also came in the other direction from those young men who were attracted to this new and promising field. The educational results of these demands were twofold; first more electricity and of a more modern character was taught to all students in colleges. The other outcome was the establishment of specialized courses in electrical engineering, in contradistinction to mechanical engineering or physical courses, that were modified to suit the new conditions. The theory upon which such courses are based is that electrical engineering is a definite and independent profession, parallel to civil, mining and mechanical engineering, but not subordinate to any of them. It involves some knowledge of these others in the same way that they require some knowledge of it. Until quite recently the independence of electrical engineering was not admitted by all, but now that it seems to be necessary to subdivide electrical engineering itself into two or three branches, it is evident that it can no longer be considered as an appendage to some other profession. In this age of rapid progress each profession will have all that it can do to take care of itself.

In designing an electrical engineering course the relative amount of attention to be given to the various subjects is difficult to determine exactly. In 1889, when the writer was called upon to decide this question, it was determined after careful consideration that a thoroughly substantial foundation in mathematics, physics, chemistry, and drafting is required, substantially the same as that demanded for civil and mechanical engineering, but with more physics and chemistry. This ground work can be laid either in a preliminary course, in which case the electrical engineering instruction is post-graduate, or it may be taught in the first two years of a four-year course. The former plan enables other general subjects, such as English and other languages, history, etc., to be included with the sciences; but the latter plan saves two years, which in this country is considered a very strong argument in its favor. The last two years of the course cover what might be called the professional work. Electrical engineering proper is begun in the second year, but it is not gone into deeply until the third and fourth years, during each of which it occupies about one-half of the sixteen or eighteen hours per week that is given to lectures and recitations. It also engages one-half of the time available for laboratory work during the the third year and about two-thirds of this time during the fourth year. Mechanical and general engineering cover the remainder of the work, considerable attention being given to structural as well as to dynamic engineering. If any change in this apportionment is necessary, it will probably consist in somewhat increasing the attention given to electrical subjects rather than diminishing it. In some institutions the proportion of electrical instruction is smaller than that indicated above, but it would seem to be inevitable that at least one-half the time must be given to electricity and its applications during the last two years. This is in addition to a thorough one-half of the time available for laboratory work during first two years, including general electricity and electrical measurements. A course in electrical engineering is compact and homogeneous, the subjects following each other or advancing side by side in natural and logical order. In this respect it is much easier to arrange such a course and carry it on than with mining engineering, for example, which includes outlyng matters like geology, mineralogy and surveying. The progress of a student of good intelligence and application is steady and sure. He usually has some difficulty in gaining a working knowledge of the action of the current. The human mind certainly does not take naturally to that idea, probably because the subject was not understood or even considered by previous generations. But after a certain grasp of the subject has been obtained, it seems to be possible to carry even average students as far as may be desired, even in advanced work. Some students of course have a greater natural taste for electrical information, but it is surprising to see men who have not shown any interest in electricity up to the age of eighteen or twenty years, become in two or three years really well versed in the subject and competent to do good work. That, to the writer, is the most unexpected result that experience has brought out in connection with electrical education.

Two criticisms are often made concerning electrical engineering education, according to one of which a graduate is not a full-fledged engineer when he leaves college, and according to the other, too many graduates are being turned out. Among the many answers to the first are:

1. The graduate has a thorough grounding in the fundamental subjects of mathematics, physics, chemistry, etc., which is very valuable not only in any technical pursuit, but also in ordinary business, and even in every day life.

2. He gets a general training and systematic methods of thinking, speaking, writing and working.

3. He gains a special and practically complete knowledge of electrical principles and applications as well as of allied mechanical and chemical subjects.

4. The total time occupied is four years. The same knowledge could not be picked up in ten years outside of an educational institution, and it is doubtful if anything like the same clearness and completeness of information can ever be acquired elsewhere.

5. The "practical" engineer knows certain branches intimately, but there are other equally important ones about which his mind is almost a blank. This is rarely the case with the educated engineer.

6. The principles of science remain unchanged so that any new invention or development is immediately intelligible to a scientifically trained mind, but has to be learned as a new subject by the practical man.

7. Electricity is so exact a science that theory can be applied directly to practice with only slight modification. For example, electrical measurements are made by the same instruments and methods and with equal accuracy in stations and factories as in college laboratories. The same machinery is also used.

8. Instruction should be firmly based upon correct theory, but it should lead the student up to the practical. Commercial apparatus and methods often make excellent examples of scientific principles. A certain amount of attention should also be given to economic and financial questions. It is not practicable, however, to give the student a certain commercial air and facility, but this can easily be acquired with a few weeks' experience in actual business. In fact, the great cry against the college graduate as a mere theorist, resolves itself when examined into this simple fact that it takes a little time to "break him in." But the period is not as long as it is for a boy from school, and after the graduate has been initiated he is a far more useful man.

It is quite a nuisance to "break" in almost any new man, but is not a very serious matter, particularly in this case, and does not involve one-quarter as much time and trouble as for a young physician. In this connection it is significant that all electrical companies prefer, and many of them require, that a young man shall be an engineering graduate in order to secure a position.

In regard to the overcrowding of the electrical profession, we can make the old but very true remark that "there is always room at the top." The writer is familiar with the experience of about one hundred young electrical engineering graduates, and in spite of the exceptionally hard times of the past few years, almost all of these men have secured fairly good positions and many of them are getting along extremely well. Certainly the average success is fully as great as in any other line of work, and it is a surprising fact that there have actually been more opportunities than men to take them, and it is usually harder to get a good man to fill a position than to obtain a place for a young engineer.

This by no means implies that the electrical engineering profession is a sure, short and easy road to fortune. Some individuals may not be fortunate in finding an opening; they may have some peculiarity of character or manner that renders them unsuited to a certain position or the enterprise with which they are connected may be crippled or stopped through no fault of their own. It should also be thoroughly realized that this profession requires fully as much hard work as any other. To be sure, the work is usually interesting, but it should be performed with more than ordinary intelligence, care and energy.

If, in course of time, electrical engineering does become overcrowded, which is by no means unlikely; even then an education in this branch would not be thrown away. As a mental training and a preparation for almost any business, it is equal to an academic course or time spent in educational or commercial work of any sort. In the future electrical matters will become more and more important to every one, and even though one may not be professionally interested in it, electricity is a grand and progressive science well worthy of the study of any mind.

LETTERS TO THE EDITOR

THE H. WARD LEONARD MOTOR REGULATION PATENT.

I NOTICE that you have published a statement relative to the counter electromotive force regulation of electric motors, wherein you have in effect given the public to understand that Mr. H. Ward Leonard prevailed over all other contestants in the interferences, among whom was myself. As such condition is totally at variance with the actual facts, permit me to explain the exact situation, that there may be no misunderstanding from a misrepresentation on the part of any one. As a matter of fact, my reductions to practices were prior to the conceptions of Mr. Leonard; and after Mr. Leonard had made propositions to me for an amicable adjustment of the interference, which were declined, he made a motion to dissolve the interference on the ground that the broad issue was not patentable over the prior art, introducing special patents. The primary examiner dissolved the interference upon this motion, citing a certain patent which anticipated all of the applicants but myself. I thereupon did not appeal, since the record in my case antedated the reference (my reductions to practice antedating the patent cited and my completion of the invention being considerably anterior to the reference). Leonard thereupon made a new motion, calling attention to the facts as above stated and asking that the examiner withdraw his decision and deny the patentability upon an earlier reference. This motion was denied. Thereupon Leonard limited his application to specific details which distinguished it from the other applications and from the prior references, and his patent 572,903 issued on Dec. 8, 1896. In that patent he has not a single broad claim, and on the other hand all of the broad claims, some thirty or more, remain in my application to be issued as the fundamental patent upon this system. Leonard's patent will be subservient to mine and a direct infringement upon my claims.

Under these circumstances, your publication implying that Leonard has succeeded in overcoming the contestants and securing the broad claims is evidently based upon a misrepresentation of the true facts. R. M. HUNTER.

Philadelphia, Dec. 30, 1896.

(Feeling that this matter is one of questions of fact between the two gentlemen interested, we have asked Mr. Leonard to state his case, and now append his reply to Mr. Hunter.—Eds. E. E.)

I have read Mr. Hunter's letter to you dated Dec. 30, 1896, which has sufficient truth in it to make it impossible to contradict him flatly, but his statement is far from fair.

I shall not attempt to rehearse the details of some six or seven very complex interferences involving nine different contestants, but will say that I have won every interference to which Mr. Hunter and myself were parties and that no interference exists between us at present. It is probably true that he has not abandoned his case, although in every issue between us I either prevailed or succeeded in showing the patent office that his claims were unpatentable.

Whether the claims of my patent are broad, or not, is of course a matter of opinion. I grant that they are not broad enough to make it necessary that I should swear back of all the art during the past eleven years in order to keep it alive in the patent office, and also to account for a delay of six or seven years in filing the patent application, and also to file affidavits as to the actual operation of a device which must bid defiance to nearly all the laws of nature before it can operate as claimed.

Mr. Hunter, however, is in the positon I have described. If by any chance he succeeds, by sufficient affidavits and sketches, in securing a patent which anticipates the good work in the line under discussion, done during the past eleven years by such men as Edison, Farmer, Lahmeyer, Pendleton, Rice, Bradley, Dillman, Weston, Mailloux, and many others, I shall certainly make no claim to it, and he will be entitled to all the credit that the securing of such a patent gives him as far as I am concerned. H. WARD LEONARD.

Hoboken, N. J., Jan. 2, 1897.

NEWARK, N. J.—The station of the Newark Electric Light and Power Company, P. N. Jackson, president, was wrecked by fire on Dec. 29, the fire starting apparently in a wooden switchboard. About twoscore dynamos were burned up or disabled. The damage is put at $175,000, covered by insurance. Resumption of service was very prompt.

"THERMO-ELECTRIC" OR NOT "THERMO-ELECTRIC."

IN your issue of Dec. 30, 1896, Professor Anthony says he "cannot see that the action of the Jacques cell is any different from the action of any other electrolytic cell, as, for example, zinc-platinum in dilute acid," except that the Jacques cell must be raised to a high temperature before there is oxidation of the carbon.

The difference is a very important one, I think, when we consider that in the case of the zinc-platinum couple in acid, alkali or water, or in any solution containing water, we have chemicals capable of attacking the zinc in an exothermic reaction; whereas, in the Jacques cell there is no substance, so far as he has made known its contents, that can, at any temperature up to the highest attainable by the oxidation of carbon, react on carbon exothermically; unless we assume that the formation heat of potassium ferrate is less than 145.5. To account for the result obtained by Dr. Jacques (1.04 volts) we must assume the formation heat of potassium ferrate to be zero. This means to assume that the highest known oxide of iron may, without either absorption or evolution of energy, be reduced to the metallic state—an assumption that seems to me entirely untenable.

The fact that certain exothermic reactions may not take place at very low temperatures, as explained by Prof. Anthony, is no proof that a high temperature will change an endothermic into an exothermic reaction. High temperature, instead of changing the endothermic into an exothermic reaction, merely supplies heat that must be absorbed in order that the endothermic reaction may take place. If the reaction can take place only through the absorption of external energy (heat), it cannot be galvanic and cannot, therefore, be like that of a platinum-zinc cell, whether it be thermo-electric or not.

THE RADIATING POWER OF INCANDESCENT LAMP FILAMENTS.

The criticism which London Lightning makes upon Mr. Converse D. Marsh's ideal filament which radiates no light is perfectly proper; but their "Reviewer of Reviews" further on gets rather involved in his own argument by forgetting that the best filament is the one which at a given temperature yields the largest amount of light for the energy expended, or which, for a given ratio of light produced to energy expended operates at the lowest temperature. These conditions depend very much upon the radiating power of the surface.

Consider a filament operated by 50 watts and giving 16 candles. Keeping the supply of energy constant, if we made the surface a poorer radiator the temperature of the filament must rise to enable it to radiate the energy supplied, and being hotter it will yield more light, although the energy supplied remains the same. If the filament, with its original surface, be supplied with more energy until its light is increased to the same amount, its efficiency will then be less than the efficiency of the poorer radiator because the amount of energy has been increased.

If the energy be still more increased, the efficiency of the good radiator can be made equal to the efficiency of the poorer radiator; but its temperature will then be much higher, its deterioration more rapid and its life shorter.

These considerations demonstrate that the poorer the radiating power of a filament the less the energy needed to produce a given amount of light, and the lower the temperature of the filament at any given efficiency.

The base of lamp filaments is amorphous carbon, which is black and smooth. This is surfaced with graphitic carbon, which is gray and not always as smooth as the base. The radiating powers of these two kinds of carbon are about as 4 to 3, the amorphous carbon being 4.

A black, unsurfaced filament which with a given amount of energy, say, 50 watts, will yield a given amount of light, can be given a thin coating of graphitic carbon, and will then yield considerably more light with the same amount of energy supplied, 50 watts. This coating will increase the surface of the filament which makes the result all the more remarkable. This change is not due to smoothness, for the base is as smooth as the graphitic surface, but the improvement is due to the poorer radiating power of the graphitic surface.

Lightning's reviewer says: "Granted that a smooth surface radiates less heat, it also radiates less light, and therefore the temperature must be raised to get equal candle-power." I think this is a wrong conclusion. I grant that at the same temperature the poorer radiator will radiate less heat, but I do not conclude that it will radiate less light, for while the total radiation is less the proportion which is light is greater; and while I am not sure that the light will be fully equal to the light from the better radiator, I believe it will be equal.

This opinion is based on observations made upon lamp filaments of various kinds, having very different radiating powers, but as I have not been able to measure their temperatures, I state this as my opinion only.

This fact that a filament with a poorer radiating surface gives more light per unit of energy expended at a given temperature, or gives the same ratio of light to energy at a lower temperature, can be easily demonstrated; but whether the different filaments, at the same temperature, give the same light per unit of surface, is not so easily determined. I hope Dr. Nichols will enlighten us on this subject.

JOHN W. HOWELL.

Newark, N. J., Jan. 3, 1897.

THE PHYSIOLOGICAL EFECTS OF X-RAYS PRODUCED BY STATIC MACHINES.

I NOTICE in your issue of Dec. 23, 1896, a brief article by Mr. G. A. Frei, in which he states his conviction that X-rays, when produced by static machine discharges, are harmless—mentioning experiments which he had made to test this supposed fact. I have only to say in answer to the idea put forward by Mr. Frei that the injury to my finger, already described in your journal, was produced by a static machine with one-half hour's exposure. Of course, the machine was one of considerable output, comparing, in this respect, with a moderate size Ruhmkorff coil. I am constrained to think that if Mr. Frei uses a machine, the electrical output of which is equal to that of a fair size Ruhmkorff in exciting the tubes, he will have no difficulty in producing the injurious effect.

I would also like to call attention to the misconception of my remarks before the American Institute of Electrical Engineers, as reported in your Society and Club Notes, page 652, of the same issue. I am made to say that the static machine is the most powerful exciter, which is not by any means what I intended to say, as it altogether depends on the size and capacity of the static machine as compared with any other device for exciting the tube. Also, in regard to the use of a tube with selected unidirectional discharges, the statement is made that a hole was melted through a platinum piece 1-32 inch thick in three seconds. This is an error; the hole was melted through an ordinary thickness of platinum used in the tube, which was much less than 1-32 inch thick; and this statement is followed by the words, "and through 3-16 inch iron in a high vacuum." This is evidently a confusion of the penetrating action of the rays, as in the experiments we made, no melting of iron by Röntgen rays produced by the tube was produced, but the statement should be that when the vacuum was very high the rays could easily penetrate very considerable thicknesses of iron. Also, it was stated that the name-plate could be seen through a fairly heavy iron casting, no thickness being given, but it was also stated that the letters could not be distinguished, although the fact that letters were there was plain enough. These, of course, were the raised letters on the name plate.

SOCIETY & CLUB NOTES

NORTHWESTERN ELECTRICAL ASSOCIATION.

Mr. George Cutter, of Chicago, has kindly agreed upon the request of Mr. Mercein, secretary of the association, to take charge of the arrangements for the Chicago delegates. Mr. Cutter writes us that he expects to run a special car from Chicago to Milwaukee on Jan. 20, by the 8:30 a. m. train over the Chicago and Northwestern Road. Delegates are requested to communicate with Mr. Cutter, should they desire to avail themselves of this opportunity. The convention is to be held at the Hotel Pfister, Milwaukee, Jan. 20 and 21.

PROF. HOUSTON ON X-RAYS.

A lecture on the theory of the Röntgen rays will be given by Prof. E. J. Houston on Friday, Jan. 8, at 8:15 p. m., before the Department of Electricity of the Brooklyn Institute, at the assembly rooms of the Academy of Music. It will be illustrated by lantern slides, and promises to prove a very interesting occasion. We are requested to state that the service of silver presented to the new man-of-war, Brooklyn, by the people of the city will be on exhibition at the Academy the same night.

LITERATURE

AUTO-CARS.—By L. Serraillier. Trans. by D. Farman, M. I. E. E. New York. Whittaker & Co. 1896. Cloth. 8vo. Illus. 249 pages. Price, $1.50.

This is a timely and interesting book, which we can cordially recommend to all interested in this important subject, about which information is so scarce. Much is written, but little is known. Indeed, a melancholy feeling comes over one in looking through these pages to note how many types are impossible, how many are too expensive, and how few combine inventive ideas with mechanical knowledge. Most of the automotors here shown will go into the scrap heap in a year or two, but the art will rear itself on their remains. The record is fairly complete in this volume, although, as it was first published in France it is not surprising to see several American machines electric and other, omitted from the enumeration.

LEGAL NOTES

THE TESLA PATENTS REVOKED IN GERMANY.

The Elektrotechnische Zeitschrift quoting the Köln. Ztg. states that the suit of the Allgemeine Elektricitäts-Gesellschaft of Berlin against the Aktien-Gesellschaft Helios of Cologne, for the revocation of the Tesla patents was tried before the German Patent Office and resulted in the revocation of the patents according to paragraph 11 of the German Patent Laws. The case will be appealed to the Imperial Court by the Helios Company. Just what "Tesla patents" were revoked is not stated. The term is usually applied in this country to those dealing with induction motors requiring phase currents for their operation.

The paragraph of the German Patent Law above referred to reads as follows.

§ 11. A patent can be revoked after the expiration of three years, reckoned from the date of publication of allowance.

1. If the patentee fails to carry out his invention in Germany to a suitable extent, or at least to do everything that is necessary to ensure its being carried out.

2. If the grant of license to others for using the invention appears to be demanded in the interest of public welfare, but the patentee nevertheless refuses to grant such license upon adequate compensation and against sufficient security.

WALKER CO. VS. GLENOAKS AND PROSPECT HEIGHTS RY. CO.—A SUIT FOR BREACH OF CONTRACT.

Mr. J. H. Gates, the Chicago representative of the Walker Company, of Cleveland, Ohio, informs us that they have begun an assumpsit suit for $15,000 against the Glen Oaks and Prospect Heights Railway Company, J. H. Seiberling, M. Seiberling, A. G. Seiberling and F. Patee, all of Peoria, Ill., for breach of contract. It appears that the Walker Company contracted with the parties named for generators and motors, and that the order was cancelled without any cause. The Walker Company are making a test case of this, and have engaged the services of several leading lawyers. It is said that a decision for the plaintiffs will put a salutary check on the practice indulged in by some companies of ordering apparatus and then repudiating the contract even after the machinery has been built, but without any justifiable cause.

CONNECTICUT TROLLEY PARALLELS.

Paralleling steam railroads by trolley lines has received a check by a decision of the Connecticut Supreme Court, which has ruled in favor of the defendants in the case of the Montville Street Railway Company against the New London Northern, Norwich and Worcester, and New York and New England

Railroad Companies. The plaintiff's only recourse is appeal to the Legislature.

THE SCHLESINGER RAILWAY PATENTS IN SUIT.

John I. Duffee, of Philadelphia, by Augustus B. Stoughton and Valentine & Brown, attorneys, of Philadelphia, have brought four suits in the United States Circuit Court, at Baltimore, against the Baltimore Traction Company, the Baltimore City Passenger Railway Company, the City and Suburban Railway Company and the Central Railway Company, for alleged violation of a patent for a device used on electric railways, granted to William M. Schlesinger, of Philadelphia, Sept. 10, 1895, upon his application filed Nov. 24, 1885, and assigned by Schlesinger to Duffee.

REPORTS OF COMPANIES

THE ELECTRIC RAILWAY COMPANY OF THE UNITED STATES.

The Electric Railway Company of the United States, whose office is at No. 1 Broadway, has applied to the New York Supreme Court, through Cephas Brainerd, Henry M. Field, Stephen D. Field and other directors, for the voluntary dissolution of the corporation, and Judge Truax has appointed John Hone, Jr., referee in the case, and set down the order to show cause for April 7 next. The company has not done active business for two years, as litigation concerning its principal patent resulted adversely to the company in 1894. The company was capitalized at $2,000,000, divided into 20,000 shares, of which 8,001 shares are in the treasury. There are a large number of stockholders, the principal ones being the Rev. Henry M. Field, 3,872 shares; Frederick F. Thompson, 1,000; Stephen D. Field, 495; Stephen J. Field, 375. The liabilities are $33,250, of which $20,000 are bonds issued to the late David Dudley Field. The assets consist of three patents, $41 cash, office furniture and old materials.

ELECTRICAL STOCKS.

The New Year has not opened with the briskness that many expected, but the undertone of strength is remarkable, and 1897 is faced with much brighter anticipations than were felt when 1896 dawned. The mere fact that in its trade with other nations this country has become a creditor to the tune of $350,000,000 is enough to show how things are going, and to prove that such failures and liquidations as now occur are no longer signs of current distress, but echoes of the sad and terrible days that succeeded each other from the beginning of 1893 to the close of 1896 almost without interruption.

Turning to the present course of the stock market, we note that local lighting and street railway securities are in better demand and much firmer. The Christmas lighting and the holiday travel were both much better than last year and the indications all point to greater liberality in this respect. The stocks quoted on the New York Stock Exchange are fairly steady. During the week, 11,316 shares of General Electric were sold at from 31⅞ to 34⅛, and 7,091 Western Union at 82½ to 83¾. On the Boston market American Bell telephone has been quoted around 206. and General Electric pref. at 75 to 77.

CABLE TO HAWAII.

Representative Loud, of California, chairman of the Postoffice Committee, has introduced a bill providing for the construction of a cable to Hawaii and Japan by the Pacific Cable Company of New Jersey. It is similar to previous bills of this kind, with the exception that it provides that the company shall give a bond of $300,000 for the performance of contracts.

RALEIGH, N. C.—The power house and car barn of the Raleigh Electric Company was burned Dec. 31. Total loss. Nine cars and their equipment were in the barn at the time. The power plant consisted of two Edison bipolar 60 kilowatt 500 volt generators, one 650 light T.-H. alternator and two 500 light T.-H. alternators, three 100 horse-power boilers, two 70 horse-power Ball engines and two 11 horse-power Frick Eclipse engines. The insurance is stated at $12,500. The lighting portion of the plant was very successful while the railway part of the plant was barely making expenses. Mr. G. L. Bunch, E. E., writes us that the details of rebuilding and re-equipment are not yet settled.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

Central Stations:

THE ELECTRIC LIGHTING AT MANCHESTER, ENGLAND.—Enormous progress has been made during the last few years at Manchester, where the five-wire system of distribution has been very successfully introduced. Considerable improvements have lately been effected which are described in detail. Two substations and an accumulator battery have been added, the first for more successful distribution, the second for equalizing loads as well as for doing away with running the central station at night. Details with illustrations and diagrams in Lond. "Elec. Rev.," Dec. 4, '96.

ARE CENTRAL STATIONS DOOMED?—By Max Osterberg. A short article opening the question of central stations versus small plants, taking care of the lighting on one square block. The economy of the latter is briefly pointed out. "Engr. Mag.," Dec., '96. Editorial comment "Elec. Eng'r.," Dec. 2, '96. Discussion from the financial standpoint by "An Engineer," in "Elec. Eng'r.," Dec. 23, '96.

MUNICIPAL LIGHTING, OR PRIVATE CONTRACTS.—Mayor John MacVickar, of Des Moines, publishes some letters received from the General Electric Company and Brush Electric Light Company; both parties expressing their views in favor of private corporations.—"Am. Gas Light Journ.," Dec. 28, '96.

Dynamos and Motors:

CALCULATION OF DYNAMOS FOR DIRECT, SINGLE AND MULTIPHASE ALTERNATING CURRENTS.—By E. Arnold. The first of a series of articles in which the author gives some mathematical deductions which he believes will materially help in the design of dynamos.—"Elek. Zeitschr.," Nov. 26, '96.

LARGEST GENERATORS FOR LIGHTING EVER CONSTRUCTED.—A two-phase, 2,400 volt, 1,500 kilowatt alternator, with a frequency of 60 cycles per second and 116 r. p. m. in course of construction for the Allegheny County Light Co., is illustrated and described in "Scient. Mach.," Dec. 15, '96.

Lighting:

MEASUREMENT OF TEMPERATURE OF FILAMENT IN INCANDESCENT LAMPS.—By P. Janet. In "La Révue d'Electricité," author explains the principle of a new method for measuring temperatures of incandescent filaments. It consists in determining experimentally, by means which are subsequently indicated in the article, the amount of heat given out by a lamp filament when it cools down from its normal temperature of incandescence to that of the air, and then equating the quantity thus determined with the product of the calorific capacity of the filament by the unknown lowering of temperature.—Lond. "Elec. Rev.," Dec. 18, 1896.

ELECTRIC TRAIN LIGHTING ON THE SOUTHEASTERN RAILWAY.—Dynamo and storage battery outfit belong to each car. The novelty in the system is the means of getting constant voltage independent of the speed at which the train is going. Instead of allowing the speed of the dynamo to vary, and regulating the magnetic field to correct for this, the dynamo is suspended so that its weight gives the necessary tension to the belt. The weight of the machine and the torque on the armature then exactly balance each other at normal output.—Lond. "Elec. Eng'r.," Dec. 4, '96.

Miscellaneous:

TREATMENT OF LEATHER BELTING.—Max Krieger & Co., Berlin, Germany, have invented a composition which adds fat to belts which have lost their pliability, and abstracts it from those which already have too much.—Lond. "Elec. Rev.," Dec. 4, '96.

STEALING ELECTRIC ENERGY.—At the suggestion of Dr. Oscar May, the electrotechnical society in Frankfurt on the Main, has proposed to the Verb. Deutsch. Elektrotechn. to take steps for having the law dealing with theft changed in such a way as to make it include the stealing of energy. Details of resolution appeared in "Elektrot. Zeitschr.," Nov. 19, '96.

THE BLOCK SYSTEM.—Correspondence of Clement E. Stretton, C. E., and J. Pigg, relating to the development of the block system for railway trains.—Lond. "Elec. Eng'r.," Nov. 13, '96.

Power Transmission:

ELECTRICAL TRANSMISSION OF ENERGY IN SPAIN.—A 19-mile transmission plant, run with 150 horse-power turbines, to which are directly coupled 110 kilowatt Siemens alternators of 6,500 volts and 50 periods. A drop of 14 per cent. occurs along the line. The step-down transformers transform to 115 volts. From "L'Industrie Electrique," abstr. in Lond. "Elec.," Dec. 18, '96.

REFUSE DESTRUCTORS AND ELECTRIC LIGHTING.—Francis H. Medhurst, B. Sc., in a report to the Fulham Vestry speaks very favorably of the use of a refuse destructor from sanitary as well as economic points of view. While the present cost of barging away refuse is 2s. 3d. per load, the estimated cost of destruction is taken at 1s. per load. Allowing 5 per cent. for interest and sinking fund, there remains an annual saving of £735.—Lond "Elec. Rev.," Dec. 11, '96.

Railways :

A RAILWAY THROUGH THE SEA.—A small road run at Brighton, England, has cars of very peculiar construction. The roadbed is under water a good part of the time, due to conditions of the tide; the cars are built as a sort of platform. For illustrated description see Lond. "Elec. Rev.," Nov. 27, '96. This road was partly destroyed by a storm early in December.

ELECTRIC TRAMWAYS FOR BRADFORD.—Mr. Alfred H. Gibbings, borough electrical engineer at Bradford, presented a report on a proposed electric railway, showing the cost of running and supporting the combination of lighting and railway work.—Lond. "Elec. Rev.," Dec. 1, '96.

Telephony, Telegraphy, etc:

AUTOMATIC SWITCH FOR CENTRAL STATION CALLS.—By Jul. H. West. This method is gotten up principally to reduce the work of the operator to such an extent, that he has to deal simply with the connecting plugs, while the drops indicating the number of the subscriber, etc., are handled automatically. A similar system has been previously described, but the one now presented is said to possess several new features.—"Elek. Zeitschr.," Nov. 26, '96.

TELEPHONE CONDUITS AND SUBWAYS.—By Dr. V. Wietlisbach. Discussion of subways in Paris and St. Paul conduits; iron pipes, cement lined iron pipes, creosoted wood pipes, terra cotta ducts, cement pipes, construction, ventilation, manholes, drawing-in cables, cable heads; terminal boxes for pole lines.—"Elec. Eng'g.," Nov., '96.

TELEPHONE RELAYS.—In a short editorial note the difficulty underlying such an instrument is pointed out, the statement being made that the receiver diaphragm vibrates with much less intensity than does the transmitter diaphragm.—Lond. "Elec. Rev.," Dec. 11, '96.

LOCALIZING FAULTS IN SUBMARINE CABLES.—By Herbert E. Cann. Author refers to the early work of Mr. Kennelly's in this direction, but suggests various changes. Several tables accompany the descriptive part of the paper.—Lond. "Elec. Rev.," Dec. 18, '96.

PERSONAL

HERR JOSEPH KAREIS, formerly chief technical adviser in the Telegraph Department of the Austrian Ministry of Commerce, and latterly Councillor-in-Chief at the Telegraph Direction in Prague, Bohemia, has been appointed Imperial Aulic Counselor. Amidst all his most pressing official duties Herr Kareis has found time to act as editor-in-chief of the "Zeitschrift für Elektrotechnik," the official organ of the Elektrotechnische Verein in Vienna, which work he has performed with great ability and conscientiousness. We congratulate Herr Kareis on his well merited distinction and wish him many more years of usefulness.

MR. J. F. OUTWATER, who has represented Mr. Hugo Reisinger of 38 Beaver street, New York, has resigned his position to return to the Edison Electric Illuminating Company of Brooklyn, with whom he formerly was for eight years. Mr. Outwater leaves Mr. Reisinger with the latter's best wishes for success in his new and important position as purchasing agent.

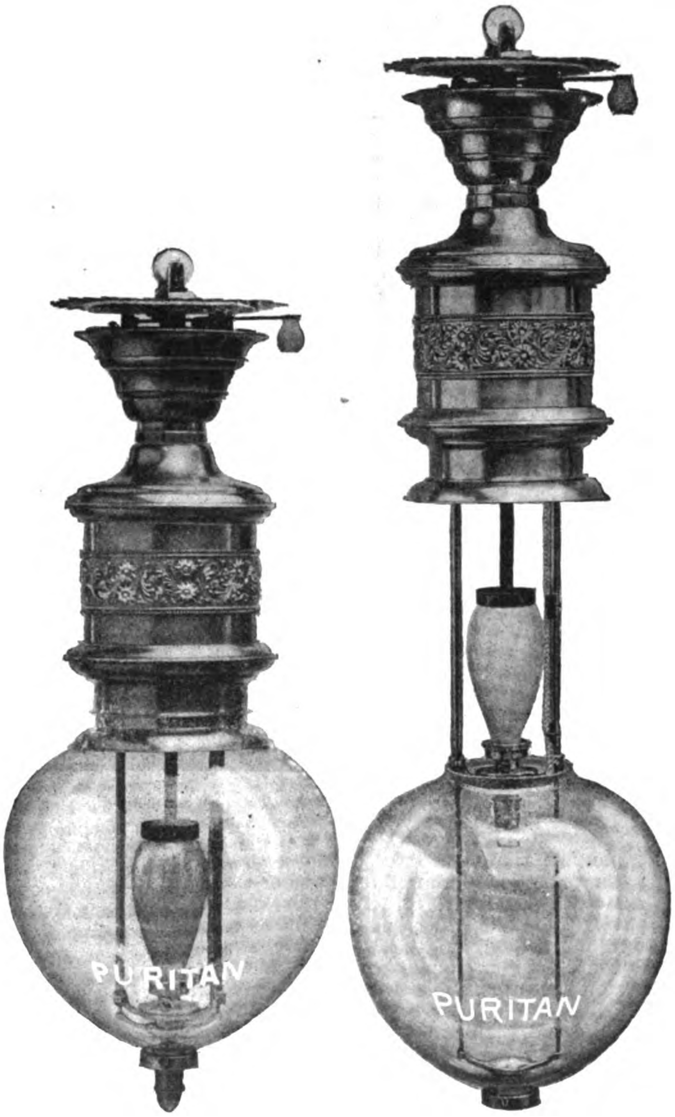
MR. EDISON and the graphophone people have come to terms, and hereafter there will be no fighting except against infringers of the joint patents.

C. J. CARNEY, a Philadelphia merchant, opining that lighting prices from the local company were too high, started a little plant of his own and has been supplying his neighbors. He is now being moved against, under the city subway ordinances, but says he is going to form a company and push the business.

TRADE NOTES & NOVELTIES

THE PURITAN ALTERNATING CURRENT ARC LAMP FOR 100 HOURS.

A SWIFT and almost instantaneous publicity and popularity has been achieved by the ingenious alternating current arc lamp, for long burning, just placed upon the market by the Puritan Electric Company, 150 Nassau street, New York City. The rapid development and revolution undergone by the direct current system of series arc lighting through the introduction of the enclosed arc, now so universal, is familiar to our readers, and it may be stated that the Puritan lamp is designed to play the same part for the rapidly extending circuits operated by the alternating current. The lamp which is shown here in two engravings is only 33 inches in length, and it is not only compact but very handsome in appearance, thus avoiding the usual attenuation and leanness characteristic of the ordinary arc light. Fig. 1 shows the lamp ready for burning; Fig. 2 shows it in position for trimming, with the globe let down. This mechanism for handling is very simple, but not more so than the details of interior construction and the devices for adjustment. Cored carbons, 7½ inches by ½ inch. are used, and give a very pleasant, steady and uniformly distributed light, when burning on circuits from 100 to 120 volts and from 7,000 to 16,000 alternations. This is wide enough range for all the practical alternating work of the day. A



Figs. 1 and 2.—Puritan Enclosed Arc Lamp.

noteworthy feature in this connection is the quietness of the Puritan lamp. It models after the clam in this respect rather than the choir.

Induced by their success with the alternating form, the Puritan Company are now introducing also a type to burn on continuous current circuits, needing only a slight manipulation of the resistance and nothing else. It is also being put on the market for regular series arc work, at 6.8 and 9.6 amperes respectively, so that it covers virtually the entire field of the arc and lays broad claim to universality.

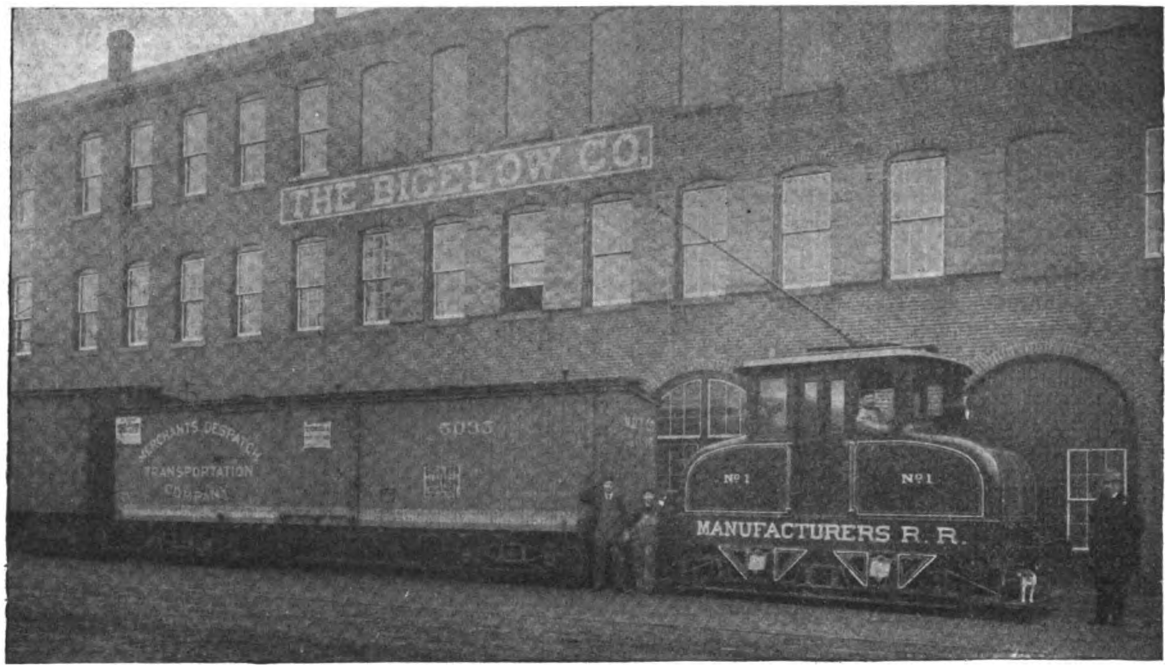
A great many of the readers of The Electrical Engineer are operating arc circuits of one kind or another, and the Puritan Electric Company address themselves particularly to them at this time, inviting their inquiries and correspondence, and above all their orders.

THE MANUFACTURERS' R. R. AT NEW HAVEN, CONN.

THE use of the electric locomotive for switching purposes in steam freight railroad yards is likely to receive a marked impetus by the fact that one is now employed in connection with the New York, New Haven and Hartford Railroad at New Haven, Conn.

This locomotive is in constant service switching freight cars between the main line of that road and a number of factories located along the river front.

The line over which it operates is about two miles long and is the property of several large manufacturers—the Bigelow Company, manufacturers of boilers; the National Pipe Bending Company, the Quinnipiac Brewing Company, the New Haven Rolling Mills, and others. It starts at the tracks of the N. Y. & N. H. R. R. at Cedar Hill Junction, which is located about one mile from the New Haven passenger depot, and follows a devious course throwing off sidings at each of the different factories. The track is of regular steam railroad type with heavy steel rails well ballasted and provided with switches and turnouts. In addition to the curves there is a 2½ per cent. grade against the load both ways on each side of Grand avenue.



THE MANUFACTURERS' ELECTRIC RAILWAY, NEW HAVEN, CONN.

The practice followed by the manufacturers hitherto in switching their cars has been for the freight engines of the N. Y., N. H. & H. R. R. to drop the cars at the Junction; from here they were hauled to the different factories by horses. This method was so slow, with the several curves and grades and so hard upon the horses, that the manufacturers were driven to the conclusion that some other method of traction must be employed. Steam traction was rejected, for the excellent reason that the line runs for some distance along a frequented thoroughfare where a switching engine would be a dangerous adjunct. That the steam locomotive would also be standing idle under steam for a large part of the day and consuming coal uselessly was also a weighty consideration.

Electric traction was finally adopted as presenting many economical and other advantages, and an order was placed with the General Electric Company for a 30-ton locomotive, which the company could guarantee would haul two loaded freight cars up a 2½ per cent. grade at a speed of seven miles an hour.

The locomotive was delivered at New Haven on Dec. 8, and on the 11th was put into actual operation without preliminary test on the line. Since that date it has been handling the entire movement of the cars between the factories and the junction.

On receipt of the locomotive, the manufacturers painted upon the cab the words "Manufacturers' R. R. No. 1," and after two weeks' experience are extremely proud of their new acquisition.

The dimensions of the locomotive are as follows: Weight, 58,000 lbs.; draw-bar pull, 7,000 lbs.; length over draw-bars, 16 feet 6 inches; height over all, 11 feet 6 inches; width over all, 8 feet 3 inches; wheel base, 5 feet 6 inches; diameter of drivers, 44 inches; number of drivers (with cast iron centers and steel tires), 4; size of journals, 5½ x 8 in.; gauge, 4 feet 8½ inches; voltage, 500; amperes full speed and normal draw-bar pull, 600; amperes, full speed and normal draw-bar pull, 300.

The motors are two in number, each axle being provided with its own motor. The motors are gearless and are supported upon a system of spiral springs resting on the side frames of the locomotive truck. The suspension being entirely upon springs, the wheels are free to adjust themselves to the irregularities of the roadbed and the wear on both tracks and motors is thus consequently diminished.

In the armature the iron clad type of construction has been followed; that is, the windings are placed in a mica lined slot cut in the surface of the laminated core. The armature and commutator are upon a sleeve through which the axles pass. The sleeve rests in bearings on the motor frame. Two projecting arms from the sleeve fit into the openings in an iron plate loose upon the axle and similar projections from the wheel enter the plate from the other side, so that, as the armature revolves, the wheels are revolved also. This coupling, being flexible, allows perfect freedom of motion. The commutators are of substantial construction and each motor has four sets of brushes.

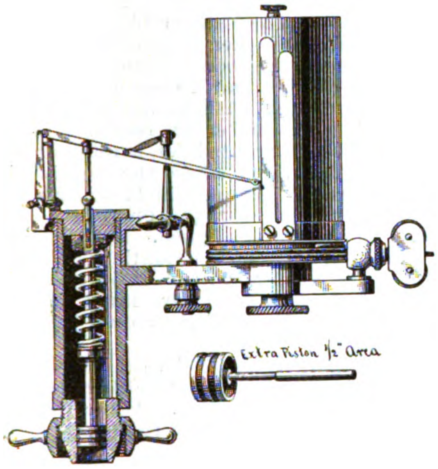
The interior of the cab is finished in cherry and contains the rest of the electrical equipment—automatic circuit breaker, controller, lightning arrester, reversing switch, air pump, air gauge, etc. The controller is the L2, series parallel type, arranged for the control of two motors. It is of the same general type as the K2, so familiar in ordinary street car practice and is provided with separate reversing switch and the magnetic blow out. The resistances are set beneath the shields and are of the packed ribbon type.

In the front of the cab and above the controller is a circular dial ampere meter reading to 500 amperes and facing the motorman is the air pressure gauge. On the other side of the cab, opposite the controller, is an oscillating cylinder air pump, driven by a motor. This furnishes air to two air tanks suspended beneath the cab and is automatic in its action.

The locomotive is provided with a chime whistle blown by the compressed air and a railroad headlight is set upon each shield. Beneath each one of the shields is an iron sand box provided with pneumatic feeding device.

Electricity for this locomotive is furnished from the Fairhaven and Westville power house, which stands on Grand avenue, about the middle of the line and the current is taken by trolley from an overhead wire suspended from brackets. The operation of the locomotive is marked by extreme smoothness and without load it can be run at almost any speed, and with load starts without jerk of any kind. It responds immediately to the motion of the controlling lever and can be backed up to a freight car for coupling as gently as the movement of a hand. One of the difficult duties it has to perform is the kicking of the freight cars over the curves in the New Haven Rolling Mill, in which there is one with a radius of only 50 feet. The locomotive can handle seven heavily loaded cars around this curve as easily apparently as it can two.

HIGH PRESSURE "ROBERTSON-THOMPSON" INDICATOR.



This instrument is designed with a special view to the indication of extremely high pressures without in any way interfering with its use as an ordinary low pressure indicator. This improvement consists in the substitution of a piston of one-quarter inch area, instead of the usual piston of ½ in. area. In order to enable the use of this smaller piston, the coupling is bored out to a smaller area, as is clearly shown in the engraving. By this means every spring may be used for pressure equal to four times the number stamped thereon, instead of two, as is the case with the ordinary indicator; that is, a 60-lb. and a 100-lb. spring, to 400 lbs. Where ordinary pressure is to be indicated, the extra piston which is furnished with it may be used.

The parallel movement is similar to the ordinary "Robertson-Thompson" indicator, being made of tool steel, with hardened joints, and providing for 2¾ inches of vertical movement in a perfectly straight line. The material and workmanship are of the best, and by the elimination of many of the complicated features usually found in indicators, the greatest convenience in use is assured.

By means of a telescopic piston rod the pencil point may be set at any height on the drum for use in connection with condensing engines. The drums are either 1¾ inches or 2 inches in diameter and provisions are made by means of taper bearings top and bottom, to take up all wear of the drum spindle.

The instrument may be changed from right to left hand in a few seconds. For use on ammonia compressors they may be had in steel. The manufacturers are Messrs. Hine & Robertson Company, 98 Cortlandt street, New York.

"CHIPS OF THE OLD BLOCK."

The younger generation is rapidly taking its place in the new field that the energy and genius of its fathers have created, and electricity is already one of the industries in which certain names are time-honored because of their identification with it. We are glad to note in the American Electrical Works, of Providence, R. I., the appearance of new blood in the persons of Messrs. F. N. Phillips and E. Rowland Phillips. These young business men are the sons of Mr. Eugene Phillips, and their taste for the intricate and difficult industry of insulated wire manufacture is therefore hereditary. For them, springing from such stock, it is simply impossible to make poor wire, and everyone wishes them as years roll by an even larger prosperity and reputation than their popular father has enjoyed these many years. As to the share taken in the business, it may be stated that Mr. F. N. Phillips has assumed the position of treasurer made vacant by the resignation of Mr. W. A. Hathaway, and that Mr. E. Rowland Phillips has been appointed superintendent of the works. Mr. Eugene Phillips, as president, and Mr. W. H. Sawyer, as secretary, who have borne the burden and heat of the day, thus receive valuable aid and reinforcement in this young but well trained enthusiasm, from which the happiest results may be confidently expected.

THE KEYSTONE SWITCHBOARD INSTRUMENTS.

THE Keystone Electrical Instrument Company, of Ninth street and Montgomery avenue, Philadelphia, are manufacturing a variety of switchboard instruments for direct and alternating current, which are very neat in appearance and possessing a number of valuable features.

Fig. 1 shows the type "K illuminated dial" instrument, the ordinary type K being without the illuminating device, but exactly similar in all other respects. Both of these instruments are handsomely finished in brass, grained by hand and lacquered. They are made in all ranges, both volt and ammeters, and are combination instruments, that is, will read with equal accuracy on either direct current circuits or alternating current circuits of any frequency. The company claim to have been the first to put such a switchboard instrument on the market.

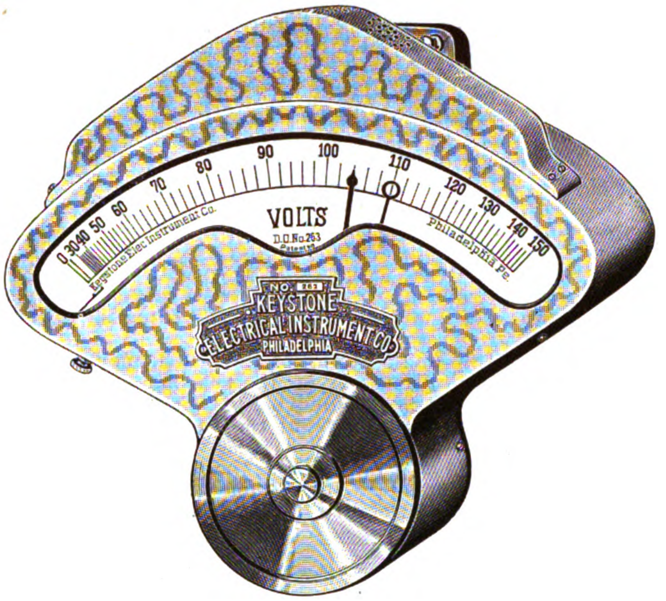


Fig. 1.—Keystone Type "K" Illuminated Dial Voltmeter.

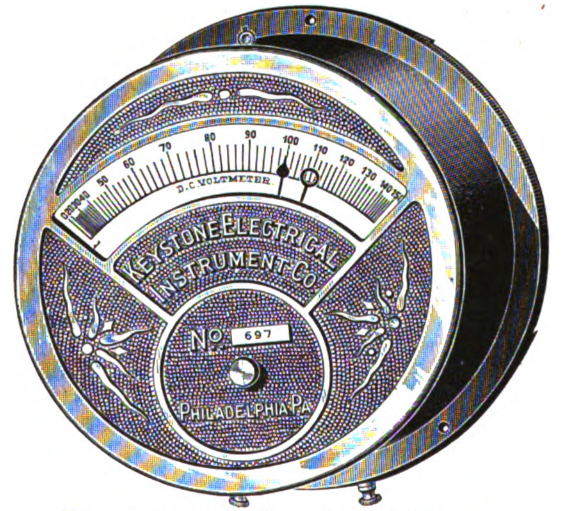

Fig. 2.—Keystone Type "R" Voltmeter.

Fig. 2 shows the type "R" instrument, the mechanism is similar to the type "K," but the case is smaller and is made in full nickel. The type "R" instruments are with combination systems, the same as type "K" or without. The latter is cheaper and very satisfactory when an instrument is wanted on one circuit only; they are calibrated for direct current or for alternating current of any specified frequency.

Fig. 3 shows the company's galvanometer ground detector mounted in a brass case grained and lacquered. This instrument is very useful in showing the extent of grounds and in indicating on which side of the line they are; it is intended to be left in circuit continually; it is designed for either direct or alternating current, as desired.

The Keystone Company also manufacture differential voltmeters mounted in type "K" cases with or without illuminated dial. These instruments are very useful when one or more direct current dynamos are run from the same set of bus bars.

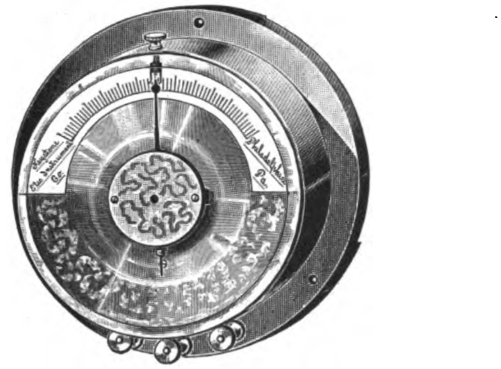

FIG. 3.—KEYSTONE SWITCHBOARD GALVANOMETER GROUND DETECTOR.

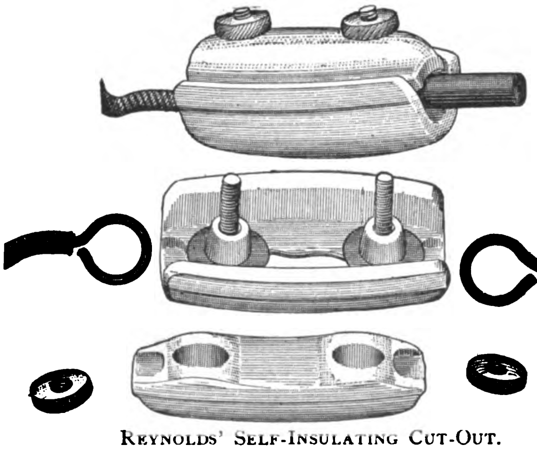
The workmanship and material of these instruments are of the best; the cases are dust proof; the bearings are jewelled, the pointers dead beat, and the moving parts are shielded from the effects of external magnetism; the ranges can be made anything desired.

These instruments are calibrated to the finest standards before leaving the factory, which is equipped with the latest and best standard units and testing appliances.

THE REYNOLDS SELF INSULATING CUT-OUT.

A decided novelty has been placed on the market, in the new "bug," the Reynolds self-insulating cut-out. This device is a radical departure from all other "bugs" and so thoroughly meets every requirement of simplicity, safety and size, that it merits careful attention.

It will be seen from the accompanying engravings that no covering is required, as complete insulation is obtained when the connection is effected by the union of the two parts. All other "bugs" can be connected up independently of any cover or insulation, and just herein lies the special advantage and safety of the Reynolds cut-out It can be connected up or refused quickly and a "ground with the fixture is impossible, as the clamping bolts are entirely encased in porcelain and thus are completely isolated from the circuit. Tape is useless with this device, which is an especially important point as regards safety. The Reynolds is claimed to be cheaper and smaller than any covered "Bug" on the market, and complies with Underwriters' requirements. It is being adopted by fixture and supply houses throughout the country.



REYNOLDS' SELF-INSULATING CUT-OUT.

The small size permits of a much smaller shell or canopy being used than heretofore; fixture manufacturers will appreciate this.

Mr. S. K. Reynolds, 136 Liberty street, New York, is the agent for its sale; his announcement will be found on the second cover page.

P. & B. PRESERVATIVE PAINTS AND INSULATING COMPOUNDS.

The Standard Paint Company, 81 and 83 John street, New York, are in receipt of a letter from an electric road which has used their armature and field coil varnish and insulating compound. The company state that they have found them in every way satisfactory. Many people are of the impression that the Standard Paint Company manufacture only the P. & B. insulating compounds and in some instances, although they are rare, they allow themselves to be persuaded that a mere preservative paint is as good as the P. & B. compound.

The company also manufacture and have for years excellent preservative paints. However, they do not possess all the insulating properties of their compound, but are claimed to be in every way superior to other so-called insulating or preservative paints, and are sold at prices far below them. They especially invite correspondence on the subject of preservatives from street railways.

We have before us a pamphlet on the subject of "Rustless Coatings for Iron and Steel," published by the American Society of Mechanical Engineers. We quote from the pamphlet as follows: "Mr. Wood, in his paper, under the group of 'lotions,' as he terms them, has apparently omitted to mention a paint which is sold in New York, and elsewhere, under the name of 'P. & B.' It is a solution of asphalt or bitumen, suspended apparently, from the unhappy odor which it emits, in bisulphide of carbon, and although the men dislike it at first, they get used to it, and once applied, I find it more permanent than any of the paints that I know of. I have used it out of doors and also for tank use. I remember an instance of a railing out of doors which has been painted for a number of succeeding years with coal-tar paint, and where the metal had been so neglected that it had rusted through in blotches and spots. Two applications of this paint were put on four years ago, and it is now as good as when first applied. It has been found equally good for tank use. It resists oxidation, and remains intact as well for brine as for water. It is so well known that I think many of the members here must be familiar with it, and I would like to know if their own experience has been equally favorable."

To demonstrate the superiority of their goods, the Standard Company are willing to send good-sized samples sufficient for practical tests of any of them free of charge. A recent circular also contains much useful information on the company's products.

MARYLAND BRASS MFG. CO.

The plant of the old Whiting Novelty Company, Aberdeen, Md., has been purchased by E. O. Bayles and others, and it will hereafter be run under the name of the Maryland Brass Manufacturing Company, which has started out with excellent prospects. The new company have added a quantity of new machinery, new boilers, etc., and have put their plant in first-class productive condition. They will manufacture metal goods of every description, from all kinds of metal, and will give special attention to a full line of electrical metal goods, for which they believe a large market awaits them.

The plant of the Maryland Company already covers some 10,000 square feet of floor space, exclusive of boiler and engine rooms, and includes machine and tool, press, plating, polishing, stamping, soldering, matting, power press, lacquer and general assembling departments, all of which are fully equipped. Mr. E. O. Bayles, the secretary and treasurer, who is well known industrially, and as a business man, will handle the financial part of the business, and the new concern under his leadership will be kept up to top notch. Mr. E. S. Whiting, whose name the company bears, remains as manager and superintendent, and with his well-known mechanical ability to which he can now give free play, the product will rank higher than ever. The new company swung into line on Jan. 1, and have already a large number of good orders to start with. They will be glad to put themselves in touch with any new lines of electrical metal work needing attention.

CRESCENT BLUE VITRIOL.—The American Electrical Works, Providence, R. I., are pushing their Crescent brand of sulphate of copper, or blue vitriol, whch, by its absolute freedom from iron, is specially suited for battery work, excelling in strength, purity and regularity of crystals. It is packed in barrels of 400 pounds, and in half barrels.

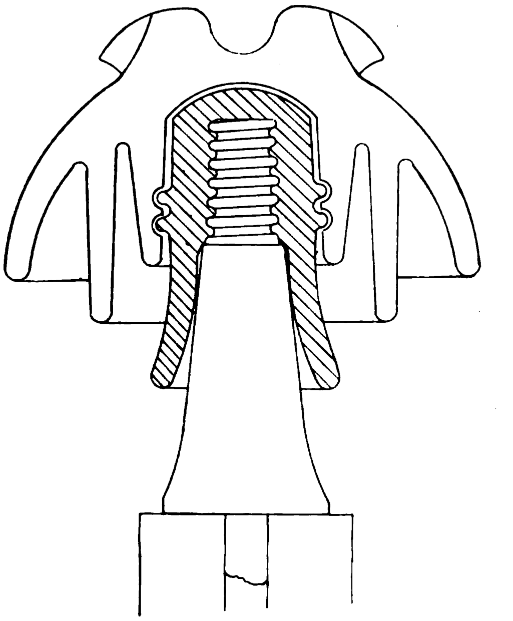
COMBINATION OF THE SIEMENS & HALSKE AND FORT WAYNE ELECTRIC CORPORATIONS.

As we go to press information reaches us of the combination effected between the Siemens & Halske Electric Company, of America, and the Fort Wayne Electric Corporation, with a capital stock of $6,500,000. It is stated that the existing plants of both corporations to the deal will be kept in operation as heretofore. It is understood that Mr. R. T. MacDonald is at the head of this formidable combination. To our Chicago representative, the Siemens-Halske Company have denied any knowledge of the matter.

NEW LOCKE INSULATORS FOR HIGH VOLTAGES.

We illustrate herewith a new insulator which has just been brought out by Fred. M. Locke, of Victor, N. Y. It is made of porcelain with a separate center insulating attachment, which may be made of either glass or porcelain. Its construction is mechanically and electrically strong, rendering it very suitable for carrying high potential currents. It has shown remarkably good results in transmitting large currents at a pressure of 15,000 volts over long lines. At a recent test with these insulators on Mr. Locke's steel pins, they carried 70,000 volts for four hours, without heating, arcing or breaking down.

These insulators present over twelve inches of surface between the wire contact and the supporting pin; about ten inches of this surface being on the under side of the insulators out of reach of direct rainfall. The faces of the bottom of the insulators are perpendicular and therefore do not afford any lodgement for foreign matter. Locke's patent steel insulating pin, the top of which is made of locust wood boiled in paraffine, is designed to be used with these insulators.



New Locke Insulator for High Voltages.

The adoption of this interesting combination of glass and porcelain will be closely watched. Mr. Locke states as the result of his study and tests that this union offers a wonderfully high resistance and results in a maximum of insulation with a minimum of puncture.

THE CUTTER CALENDAR.

We have received from The Cutter Electrical & Manufacturing Company, of Philadelphia, an extremely handsome and original calendar. The conventional calendar pad is mounted upon a heavy card 11 x 14 in. in size, upon which is printed a full detail section drawing of the well known I-T-E Circuit Breaker. The effigy of the circuit breaker is drawn to a three-quarter scale, and as a specimen of artistic printing it is quite remarkable. All the various metals used in the circuit breaker are printed in their equivalent colors or bronze, necessitating on each calendar eight separate impressions. The whole is then handsomely embossed and the effect produced is extremely novel and satisfactory. The arrangement of the design is such that any one having the least knowledge of the use to which circuit breakers are applied cannot fail to be impressed by the simplicity of its construction, all the parts being plainly represented and their functions clearly suggested.

The success which the Cutter Company have met with in the past year, in their development of this device, is extraordinary. Although they have devoted the best part of five years to the study of circuit breakers, it is only within the past two years that the device has been placed upon the market as an absolute success, electrically, mechanically, and, we may add, artistically. I-T-E circuit breakers have been specified in most, if not all, of the important buildings which have been erected in the course of the past year, and important shipments to various foreign countries are reported. The range of manufacture is large, more than ninety sizes and types of circuit breakers being manufactured.

We believe that this calendar will prove extremely valuable as a means of bringing the circuit breakers into still further prominence, and every one interested in this device should make sure of receiving a copy.

NEW DE VEAU TELEPHONE APPARATUS.

The engravings shown herewith illustrate the admirable new telephonic apparatus put upon the market by De Veau & Company, 32 and 34 Frankfort street, New York City, who have made a high reputation for their telephonic apparatus. Fig. 1 shows the De Veau desk set, and represents the latest type of this instrument. It can be used with either the buzzer and strap key or the magneto call. It has a wooden base, the standard and metal parts are all nickeled; and it is so swiveled that it can be swung through a full half circle. The hook switch is very simple and safe, open to inspection all around, and fitted with platinum contacts. The movement of the hook of course cuts the battery in and out. In the base of the set are the induction coil and the buzzer, and the calling key in the shape of a button. The set has green silk conductor cords. With only one cell of battery, the apparatus is very sensitive and loud. The set is very pretty and ornamental, and stands only about 9 inches high.

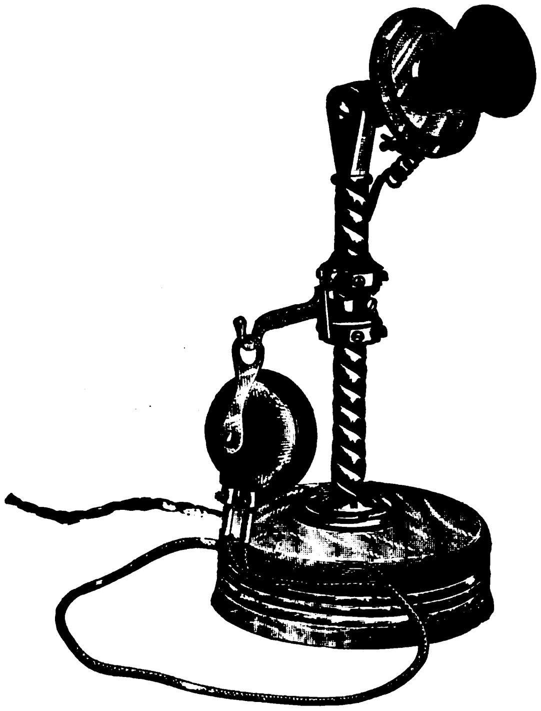


Fig. 1.

Fig. 2 shows the combination of the receiver and transmitter in one piece for the hand. It is only about 9 inches long and is thus very compact and convenient. The handle is of rubber and all the rest is metal nickel plated. There is a button switch to cut the battery in and out, in the side of the handle, and there is a screw for allowing the receiver to be raised or lowered in the handle tube to suit the convenience of the user. Otherwise both the receiver and transmitter are rigid and thus do not get out of adjustment. The induction coil is exterior to the apparatus and is placed anywhere adjacent that is handy.

Fig. 3 is literally a central telephone station in itself, and shows the De Veau metallic circuit intercommunicating telephone. Every one of the ten circuits shown is metallic, and as there is thus no common wire, there is a complete absence of inductive cross talk. The dial switch is composed of two parts, insulated one from the other so as to carry the two wires separated. The movement of the arms on the numbered and corresponding blank knobs makes the contacts for the talking circuits at each given point by pressing the knobs.

An important point is that the battery can be centralised if necessary, or desired, thus dispensing with the local battery at each station. In use, the dial pointer is turned to the number to be called; the button on the side of the box is pressed to ring up the other party, who, if disengaged, gets the signal. If the line is busy, the call is made again later. If free and ready, the receivers are taken from the hook and conversation begins at once without delay. A magneto can be used in place of the battery bell, if wanted. The transmitter swivels and is adjustably mounted on the box containing the induction coil and other detail devices required for conversation. This De Veau telephone apparatus is moderate in cost, well built, gives excellent service, and overcomes the great annoyance of induction which causes so much trouble and failure in telephone work. It is built in oak and walnut finish, and is an ornament wherever placed. The company will be glad to receive inquiries and orders.

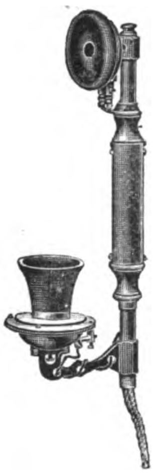

FIG. 2.

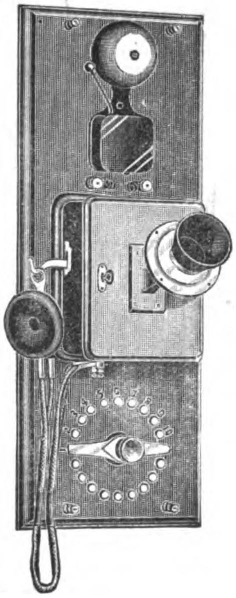

FIG. 3.

QUICK DELIVERY OF BRUSH ARC APPARATUS, AT NEWARK N. J.

Tuesday night, December 29, at 9:30 a telegram came to The Brush Electric Company, at Cleveland, announcing that the large station of The People's Light and Power Company, of Newark, N. J., was on fire and would be a total loss, and asked what they could do in the way of sending them new machines. After calling them up on the telephone, finding out exactly what they could use, the men were got together at the shop at two o'clock Wednesday morning and work was started on the large order. All of the old time Brush men were called to the shop and the way they took hold and got out the machines was simply marvelous. To put together, test, and box a dozen large dynamos within the space of 24 hours, will give work to a very large number of men and with the 50 or 60 men that were called upon to report at the shop at two o'clock in the morning it was a feat which no manufacturing company, we think, has ever been able to beat. Special arrangement was made with the Pennsylvania R. R. Company for a train with right of way from Cleveland to Newark. Passenger engines were taken to draw this train. At seven o'clock Wednesday morning seven cars were put into the siding of The Brush Electric Company's works and work was immediately commenced on the loading of the dynamos. At ten minutes after three the last dynamo was in and the train left the shop, going to the yards to get well oiled and carefully looked over before starting on the long journey. This train went by the Brush shop, going East, at 3:40. It arrived in Pittsburg at 8:40 and reached Newark Thursday morning about noon, being the first car load of machinery from any manufacturer to arrive at Newark. Thus, in the short space of time—37 hours after the receipt of the telegram announcing the fire—The Brush Electric Company had 18 big dynamos at Newark ready to be put into actual service and as a matter of fact some of these machines were put into service Thursday night.

Here is a record that any manufacturing company might well be proud of.

THE WALKER PLANT IN THE NEW WALDORF HOTEL.

The New Waldorf Hotel, which occupies the block between Thirty-third and Thirty-fourth streets on Fifth avenue, New York City, is to have one of the most extensive electric plants in this country and the Walker Company, of Cleveland, Ohio, have been awarded the contract for furnishing the electrical apparatus.

In many respects this plant is unique and interesting and possesses the distinguished feature of being the largest isolated plant in the world, having a capacity of 25,000 lights which are to be used only for lighting this building.

The engine room is to be one of the most elaborate and handsomely fitted rooms ever designed for the reception of any kind of machinery. It is to be somewhat on the plan of the marble engine room at Keith's Theater, Boston, but will be much more elaborate and extensive, the walls, wainscoating and ceiling being of onyx and tastefully decorated. The floor is to be of marble of a pleasing design.

Around the upper portion of the room is to be a balcony which completely surrounds the place and from which guests and visitors to the hotel may view the machinery below. In this way the engine room will be made one of the attractions of the hotel and will certainly prove as interesting an entertainment to a large class of its patrons as the court yard or the finest parlors.

The generators are to be of the Walker type manufactured in Cleveland, Ohio. There are to be six generators in all; four of them of 250 kilowatt capacity and two of 100 kilowatt capacity. The first named generators are of the extremely low speed of 90 r. p. m., and the other two run at 100 revolutions per minute.

If these machines were wound to deliver their output when run at a speed which would be considered the maximum safe working speed, they would be capable of suplying 50,000 lights, enough for a good sized city. This slow speed was desirable for two reasons. First, because the slow speed very much reduces the vibration of the machine and increases its life, and second, because this speed enables the direct connection of the dynamo to a Corliss engine. High speed engines are invariably used on all direct connection isolated plants, and the proposed Waldorf Hotel plant is probably the first of its kind in this respect. The engines are to be of the Allis-Corliss type, direct connected to the Walker generators.

The machines are to be multipolar, the field frame being of cast iron, while the pole pieces are of laminated wrought iron supplemented with a steel pole shoe, this being a special feature of the Walker machinery.

The armatures are to be of the regular Walker straight-toothed end coil type and are to be provided with the company's regular end flange which forms a substantial cast iron pocket to support and protect the ends of the coils. The windings are to be of the barrel type and by this means almost all of the wire comes under the influence of the pole pieces and is active. The machines are to be especially well finished. All brass parts are to be buffed, polished and laquered and the bodies of the machines are to be filled, smoothly enameled and elaborately decorated.

The Walker Company's machines have always been particularly noted for the practically negligible movement of the brushes from no load to an enormous overload.

Mr. John Jacob Astor, the owner, is famous for his knowledge and interest in electrical matters and has determined to have the finest plant of its kind installed in his hotel, and toward this end has secured the services of the eminent electrical expert and engineer, Mr. C. O. Mailloux, of New York City, to supervise this extensive operation.

Those principally interested in the Walker Company are ex-Governor Flower, J. W. Hinkley, Perry Belmont, Anthony N. Brady, of New York, Dallas Sanders, of Philadelphia, and several Boston capitalists, together with S. E. Williamson and Jacob B. Perkins, of Cleveland.

"PIONEER."—One of the severest tests known in the field of electric lighting was lately completed at the well known shoe house of Cammeyer & Company, Sixth avenue and Twentieth street. From a practical and scientific standpoint every point was carefully considered and the order to light the large building throughout awarded to the "Pioneer" enclosed arc lamp.

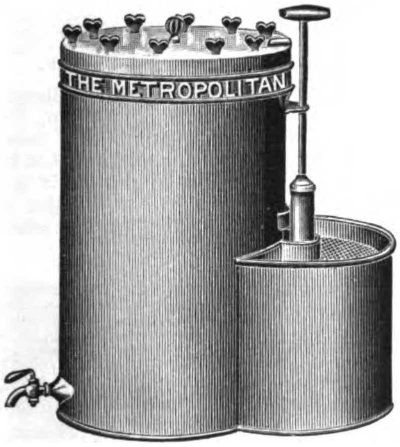
THE "HABIRSHAW WIRE" NEW YEAR RECEPTION.

With Dr. Habirshaw himself at their head, the staff of the India Rubber and Gutta Percha Insulating Company held their New Year reception on the last day of 1896, at the sales headquarters, 15 Cortlandt street. This celebration has come to be regarded as a fixture by the electrical fraternity, and the number now gathering to exchange greetings and good wishes runs into hundreds, "everybody" being there. Messrs. Godfrey, Harrington and Olsen make ideal hosts, and no attention was neglected that could make their guests feel at home. Liquors of every description, cigars of the choicest brands, a cold collation, scores of good fellows and an unending succession of good stories—all new—contributed to make the event once again delightful and memorable. When it comes to combining technique with popularity, the "Habirshaw crowd" is hard to beat, and the evidences of kindly feeling towards them all, and their company's products, were overwhelming on Thursday afternoon last.

THE METROPOLITAN OIL FILTER.

In oil that has been used for lubricating journal-bearings there are very small particles of metal worn from the bearings which are suspended in the oil. These particles of metal may be effectively removed from the oil by forcing the oil under pressure through a diaphragm or other body of porous material, the material being thus permeable to the oil when finely divided, but the pores being of insufficient size to permit the passage of the particles of metal. The removal of the particles of metal thus held in suspension makes the filtered oil practically as good for lubricating purposes as it was originally.

A filter specially designed to remove these fine particles is the Metropolitan oil filter, illustrated in the accompanying engraving and manufactured by the Metropolitan Electric Company, of Chicago. In this apparatus there is provided a receiving-tank into which the oil to be filtered is poured, a perforated cover being provided for the tank, which prevents the entrance of foreign matter, such as waste and the like. A pump forces the oil from the receiving-tank into a pressure-tank, the pressure-tank being air-tight, whereby a pressure may be produced in the tank by forcing into the tank a sufficient quantity of oil, or, if there be but a small quantity of oil in the receiving-tank, air may be pumped into the pressure-tank to provide the required degree of pressure. A pipe extends from the pressure-tank to a filtering-receptacle in which is placed the filtering diaphragm of blotting paper; the oil is thus forced through the diaphragm under pressure and passes to an oil-tank, from which it may be withdrawn for use as desired.



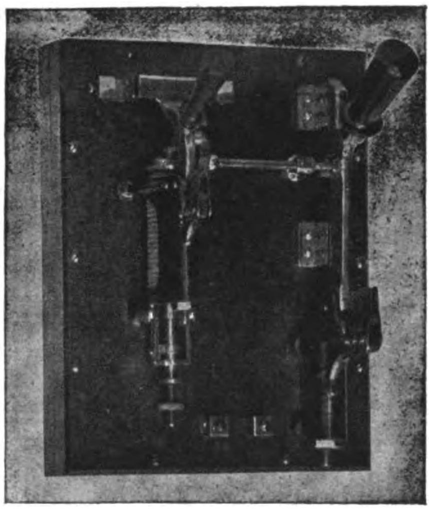
The Metropolitan Oil Filter.

LARGE TROLLEY CONTRACT IN NEW YORK CITY.

The Third Avenue Railroad Company has just concluded a contract with the General Electric Company for the electrical equipment of its new extension from 165th street and Amsterdam avenue, via the Kingsbridge Road to Spuyten Duyvil Creek, a distance of about two and a half miles. The power house will contain a battery of 15 Babcock and Wilcox boilers having a total capacity of 2,500 horse-power. The engines will be of the Allis-Corliss type from the shops of the E. P. Allis Company, and will be three in number of 1,100, 700 and 500 horse-power capacity respectively. Each engine will be directly connected to a G. E. multipolar railway generator, of 800 kilowatt, 500 kilowatt and 300 kilowatt capacity respectively. The switchboard will be of the standard G. E. panel type, and will be equipped with the most recently developed switchboard apparatus. The overhead wires will be suspended from brackets set on ornamental central poles and each alternate pole will carry a 1,200 candle-power arc lamp, current for which will be generated by two direct-connected 125 arc light Brush dynamos. The feeders will be laid underground. The cars will be of the handsomest construction obtainable and will be set on double trucks. Each car will be equipped with two regular motors of the capacity of the G. E. 1,000, one motor being set on each inside axle. The first motor contract contemplates 50 double motor equipments.

THE ELDEN ALTERNATING CURRENT CIRCUIT BREAKER.

The accompanying cut illustrates an alternating current circuit breaker recently patented, and now being brought to the attention of users of alternating apparatus, by L. L. Elden, 305 Congress street, Boston. The breaker is designed to be placed directly on the dynamos, in a position easy of access, and is quickly and easily connected in circuit. It is claimed that this device is a sure preventive for all the troubles that short-circuits, lightning discharges, etc., cause central station managers; and the record of the device, in stations where it has been in use, is reported to be an exceptional one. At a recent test of the breaker, at the station of the Boston Electric Light Company, it was shown that the application of a dead short circuit at the switchboard produced no visible effect on either engine, dynamo or belt, and, but for seeing the circuit breaker open, none present would have known that a short circuit had been applied. All the alternating machines of this company were equipped two years ago with these breakers, after putting them to severe tests, and since that time the manager states that they have saved the company many times their cost and have never failed to operate in any case.



Elden Alternate Current Circuit Breaker.

The adjustment of the breaker is accomplished by means of weights and fixed distances, with an entire absence of springs, making its operation absolutely reliable at all adjustments. This circuit breaker embodies a new device to prevent arcing at the switch jaws, which is certainly effective as there is no sign of arcing when the breaker opens, even under very heavy loads of two to three hundred amperes. It would seem that this breaker would prove to be of interest to all users of alternating apparatus.

A TEMPERED COPPER EDICT.

The Mitchell Tempered Copper Company, of Corry, Pa., have issued a very striking edict in the shape of a neatly finished bull. It is made of their metal, and very cleverly done, both artistically and as showing the excellence of the material. It stands three inches high, is four inches long, and makes a good paper weight. Our readers should write for one each. The Mitchell stock farm is of large capacity, and the proprietors believe that with this bull they are achieving what the Scotch would call a coup d'etat, in the way of surprising their friends.

DRUM ARMATURES IN BATTERY MOTORS.

FOR some time there has been little progress made in the design of battery motors, but lately the Kent Electric Manufacturing Company, of Worcester, Mass., have been improving their machines greatly by the substitution of a drum armature in the place of the common three-pole. If, in any place, high efficiency is required, it is with battery motors, where the current supply is limited to a very great extent.

Fig. 2 shows the three-pole armature between two field mag-

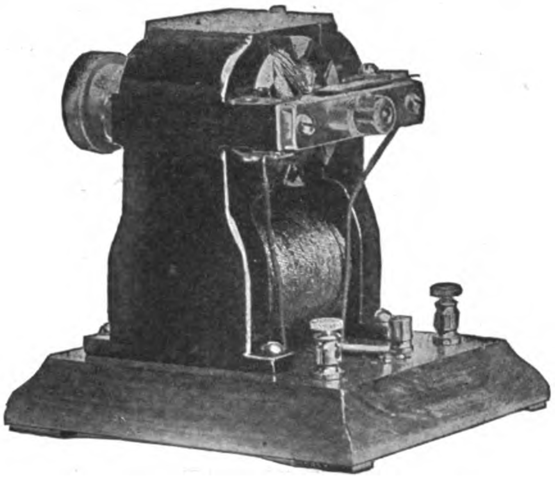


FIG. 1.—KENT DYNAMO MOTOR.

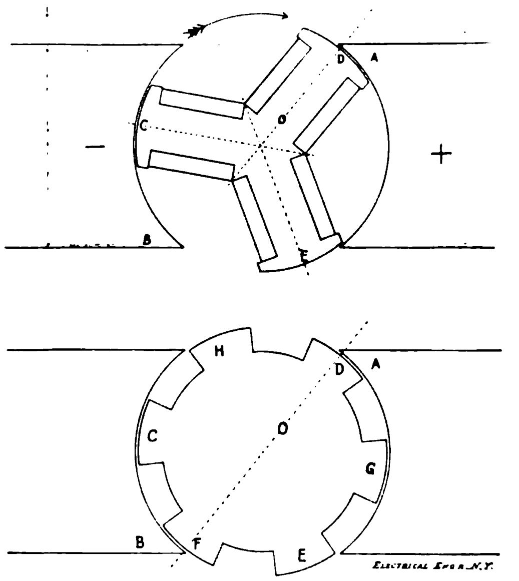
equipped with their drum armature. The armature of the machine is 2⅛ inches in diameter by 1¾ inches long, and has a magnetic cross section of three square inches. With the ordinary three-pole armature, the magnetic torque is unevenly distributed at the different positions in a revolution. This gives a rattling motion to the armature, especially with a load, and consequently a great wear on the bearing.

Fig. 2 shows the three-pole armature between two field mag-



FIGS. 2 AND 3.—KENT BATTERY MOTOR.

nets. At the position in which the armature is shown there is a pull between A and D which gives the armature a torque in the direction of the arrow; also in the direction of the radius O. As the pole E is magnetized positively, there is, of course, no torque between E and the positive pole, and as the distance between B and E is very great, there is very little torque between these. As there is practically no magnetism in the pole C, there is little torque between this and the negative pole of the field. Now, this leaves the radial pull between D and A with nothing to balance it on the other side of the armature, consequently the whole armature will be pulled in that direction.

Again, as the pole E approaches B there will, in the same way, be a radial pull between E and B with no support on the other side. since D has moved round, and has practically no magnetism. Then the whole armature is pulled in the direction B. This motion from side to side creates a great wear on the bearings, and in a short time the bearing will wear and come to have the oval shape.

Fig. 3 represents the new Kent armature, which practically has 6 poles. Now, as pole D approaches pole A, and the radial pull O D is exerted, there will be a corresponding radial pull diametrically opposite in the direction of O to B. In the same manner as H approaches A, E will approach B, and so on.

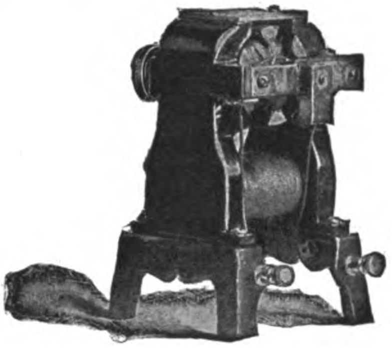


FIG. 4.—KENT MOTOR ON IRON BASE.

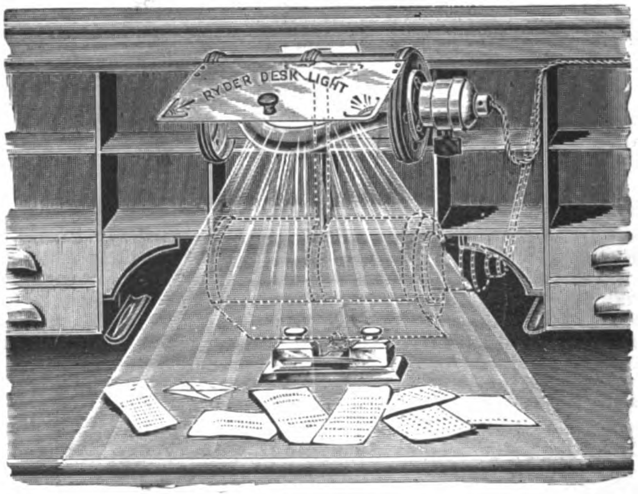
Thus, it will be plainly seen that this armature will not be pulled from side to side, thus giving a constant, steady torque.

One of the most gratifying results of these machines is that they will run as a dynamo, which also proves their efficiency as a motor. Another feature is the self-oiling bearings, which are shown in Fig. 4. The chamber just below the shaft contains a wick saturated with oil which lubricates the bearings. These machines have a capacity for work requiring about the same power as a sewing machine.

THE RYDER DESK LIGHT.

WE illustrate on this page a new desk light just brought out by the firm of A. H. Ryder & Co., 180 Broadway, New York City. It contains a number of new and special features, and is regarded by the makers as constituting a distinct advance in this field. The appliance is made to attach easily to the upper front or partition of the desk, and the lamp inside is thoroughly hooded, so that one gets all the light on the papers and none of the glare in the eye. The screening portion, however, travels smoothly on flanges at both ends and thus a considerable upward or downward range of angle can be given to it. The end adjustment permits fitting to any style of roll or upright desk, and there is also a very ingenious side adjustment, which allows the light to be specially directed at will to either side. A great feature is the manner in which by its travel upon itself, so to speak, as shown by the dotted lines in the engraving, the whole thing can be folded down inside the desk, out of the way. It thus avoids all the dust and dirt that inevitably accumulate on apparatus left exposed, for the woman who sweeps out one's office usu-



RYDER DESK LIGHT.

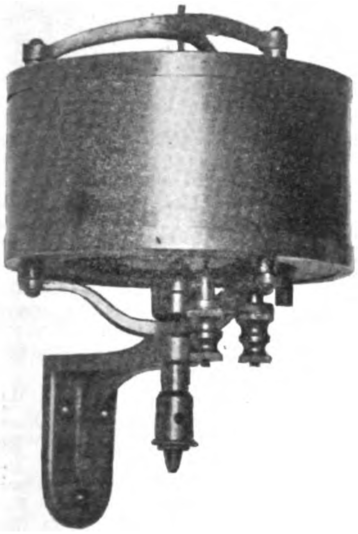
ally cleans the floor only to fill the air with dust that settles all through the night and that often becomes a nuisance and danger for electric and other apparatus, even to the extent of short circuiting a lamp or insulating a fan motor commutator bars. Mr. Ryder avoids all this by simply storing away the lamp in the desk.

The cylinder contains also an ingenious device for holding the lamp socket in place, and for adjusting to any make. The cylinder itself is corrugated with white enamel inside, casting a most brilliant reflection. In the cut, the eye shade is thrown up higher than it is used in practice, to show how the parts are placed together, etc. The shade of course is adjustable at will.

A. H. Ryder & Co. make also this general design in single and double portable lights suited to flat top desks and tables, and as an ornamental attachment for music racks. The workmanship of all styles is admirable, and the prices are such as to make it an inducement to buy. The firm will be glad to receive inquiries and make attractive quotations.

THE COX THERMO GENERATOR.

THE accompanying engraving illustrates the latest form of thermo-generator designed by Mr. H. B. Cox, who has established works for its manufacture on a large scale at St. Albans, Herts, England. These generators are operated by a Bunsen gas burner and once started require no attention for an indefinite period. They are designed to take the place of primary batteries for all purposes to which such a battery can be applied, and are adapted for telegraph, telephone, medical, X-ray, fan motors, and a great variety of other light work.



THE COX THERMO GENERATOR.

The Cox generator, which was fully described in The Electrical Engineer of Sept. 9, 1896, gives an output of 5 amperes at 2½ volts with a consumption of 2½ cubic feet of gas per hour, and can also be operated with an oil burner. The convenience of such an apparatus, doing away, as it does, with the annoyance of batteries, must be evident, and now that the generator is ready for the market, a heavy demand for it may be looked forward to.

EXTENSIVE SUBWAY SYSTEM FOR SYRACUSE, N. Y.

The city authorities of Syracuse have just granted a subway franchise to Eugene Hughes & Co. A large expenditure is involved. Mr. Hughes makes the following statement:

"I have only to say that I asked for the franchises in good faith, and that I intend in good faith to construct and operate under them. The bond furnishes adequate security and the subway franchise provides a most fair way for the city to acquire ownership. Last summer I made application to the city, and, up to date, no person or company has offered more favorable terms or considerations to the city. I expect that the subway will yield a fair revenue upon the investment until such time as the city succeeds to the ownership. A properly constructed subway in this city will cost much more than I have heard stated by others. I have done considerable contract work and know about what such work costs, and I now say that within the next year a subway system satisfactory in every particular and sufficient to meet the requirements of the communiy for the next 20 years, will be constructed throughout the business portion of the city. The opposition of the old companies does not surprise me, and the proposition of my fellow townsmen shows for itself that it is less favorable to the city than mine. We intend to give cheaper and better telephone and electric light and power service.

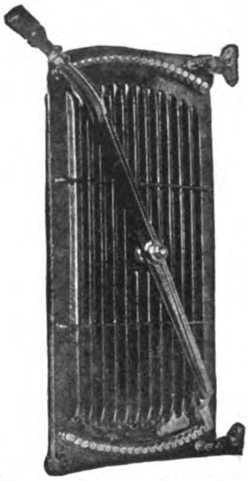
John F. Gaynor and myself are the principal parties interested in these franchises. For incorporation purposes more than two persons are necessary, but the other interests will be practically nominal.

We hope the people who are now opposing these enterprises will suspend their judgment until we can demonstrate what we can and will do on behalf of the city."

The subways are to be built during the year 1897, and it is said that a good deal of new lighting and other work will also be taken in hand.

NEW LEONARD THEATRE DIMMER.

THE accompanying illustration shows a new form of theatre dimmer just being introduced by the Ward-Leonard Electric Company. This theatre dimmer is of the well-known Carpenter enamel type and effects a most remarkable economy in price and space. Although the former rheostats of this company have been conspicuous because of their low price and small space the present type makes a reduction in both price and space of not less than 50 per cent. As will be noticed from the illustration this form of dimmer when arranged in banks entirely avoids the necessity of any connecting wires. These dimmers are made either interlocking or non-interlocking, as desired.



WARD-LEONARD RHEOSTAT.

NEW IRON ARMORED CONDUIT OF THE I. C. & I. CO.

As will be noted in our advertising columns, the Interior Conduit and Insulation Company, of New York, announce that they have placed upon the market a new and improved iron armored insulating conduit. This conduit is a development of their well-known iron armored conduit which has met with such success during the past few years. The results attained in iron armored conduit as manufactured by the above company while being far in advance of any old method of wiring, have nevertheless indicated certain lines wherein this product could be improved to more efficiently fulfill its functions. To attain this end the company have bent their best endeavors during the past few months, not only to obtain a better article, but at the same time secure one which could be produced at a lower price and thereby assist in cheapeening the cost of first-class electrical work. This conduit is far superior, possessing advantages in that it is extremely light, has a smaller outside diameter for a given internal diameter, and, moreover, has greatly increased insulating properties. The insulating lining being of a flexible nature, it is not affected by bending and the insulation under such conditions is not impaired. It will withstand a temperature of 175 degs. Fahr. without becoming in any way softened or "tacky." Any ten-foot section will show an insulation of 11 megohms after being filled with water for ten days.

This new product has met with instant recognition by the trade at large, and the Interior Conduit and Insulation Company have thus still further enhanced the value of their well-known system of electric wiring.

ADVERTISERS' HINTS

CHAS. BESELER, 218 Center street, New York, advertises stereopticons and magic lanterns.

THE BOSSERT ELECTRIC CONSTRUCTION COMPANY, Utica, N. Y., invite comparison of their goods with others. They are headquarters for distributing boxes.

A. A. McCREARY, 136 Liberty street, New York, is better prepared than ever to furnish metal half shades in aluminum and tin.

IDEAL ELECTRIC CORPORATION, New York City, state what they claim and what they do not claim for their new 100-hour arc lamp.

THE GOODYEAR VULCANITE COMPANY, 353 Broadway, New York, make a specialty of hard rubber goods for electrical purposes.

THE WARD-LEONARD ELECTRIC COMPANY, Hoboken, N. J., have greatly reduced the price of their theatre dimmers. There are over 1,000 in successful operation.

THE SPRAGUE ELECTRIC ELEVATOR COMPANY, New York, give a list of buildings varying in height from five to thirty-one stories in which they have installed from two to twenty-three machines.

M. H. WEIL & COMPANY, 725 Broadway, New York, are open for accounts in novelties and specialties.

EMIL GREINER, 146 William street, New York, is making an X-ray focus tube which he claims to be the best.

I. S. SPENCER'S SONS, Guilford, Conn., furnish fine gray iron castings and also high-grade brass and composition castings.

THE ADAMS-BAGNALL ELECTRIC CO., Cleveland, O., illustrate their "ad." with diagrams of connections of the arc lamps manufactured by them.

THE STILLWELL-BIERCE & SMITH-VAILE Co., Dayton, O., engineer and equip complete water power plants, guaranteeing the highest efficiency and closest regulation.

THE BRYAN-MARSH COMPANY, 136 Liberty street, New York, have made their "ads." very interesting with microscopic views of the different parts of an incandescent lamp, of which they manufacture and sell great quantities.

THE GENERAL ELECTRIC COMPANY call attention to the fact that they are the only electrical company who manufacture complete electric equipments for every class of work

THE LECLANCHE BATTERY COMPANY, New York City, remind the trade that for twenty years their batteries have maintained a high position in the field. Their record has been an enviable one.

WAGNER ELECTRIC MFG. COMPANY, St. Louis, Mo., are supplying high potential switches for street railways, central stations and isolated plants.

THE INDIA RUBBER AND GUTTA PERCHA INSULATING COMPANY, 15 Cortlandt street, New York, will, as in the past, maintain the undisputed quality of their wires and cables.

THE E. G. BERNARD COMPANY, Troy, N. Y., say their dynamos and motors are a perfect combination of science and mechanical skill.

THE CONSOLIDATED ELECTRIC SUPPLY COMPANY, Bennett Building, New York, are the agents for the "Teutonic" incandescent lamps and "Consolidated" insulated tubing.

PETEREIT-WEHRLE MFG. COMPANY, 206 Center street, New York, furnish novelties in brass turning, screws, cocks, gas and electric fittings.

HEBER WELLS, 155 William street, New York, makes pattern letters for iron and brass castings of any size and style.

W. S. HILL ELECTRIC COMPANY, New Bedford, Mass., claim their switches and switchboards lead the world.

THE C & C ELECTRIC COMPANY, New York, show a direct-connected 16 kilowatt generator for isolated lighting, which is equally adapted for marine service.

THE WESTERN ELECTRIC COMPANY, New York and Chicago, state they are headquarters for shades, reflectors, hoods, etc.

THE S. & B. ELECTRIC COMPANY, 74 Fulton street, New York, call attention to their "Famous" primary batteries, X-ray outfits, motors, medical batteries, and general supplies.

THE NEW YORK ACCUMULATOR & ELECTRIC COMPANY, 150 Nassau street, New York, furnish storage batteries for all purposes.

THE GARVIN MACHINE COMPANY, New York, equip complete plants for the manufacture of electrical goods and machinery and carry at all times a full line of metal working machinery.

THE CENTRAL ELECTRIC COMPANY, Chicago, offer hearty congratulations to The Electrical Engineer on the attainment of its sixteenth year and at the same time wishes all other electrical engineers a happy and prosperous New Year. The wish cannot be other than cordially reciprocated.

J. B. COLT & CO., 115 Nassau street, New York, carry in stock everything in the line of stereopticons and magic lanterns. Their patrons include many well-known institutions of learning, hospitals, theatrical companies, etc.

THE FARR TELEPHONE AND CONSTRUCTION SUPPLY COMPANY, 342 Dearborn street, Chicago, continue to manufacture and sell telephones for interior, local and long-distance work.

THE SHULTZ BELTING COMPANY, St. Louis, Mo., have not been saying much recently, but they find no trouble in selling their belts and they are popular as ever.

THE BERLIN IRON BRIDGE COMPANY, East Berlin, Conn., show in their "ad" this issue the model machine shop built by them for the Ball & Wood Company, at Elizabethport, N. J.

THE ELECTRICAL MERCANTILE AGENCY, 316 Broadway, New York, issue a credit reference book containing the names and ratings of all the electrical houses in the United States and Canada. They also maintain a collection department.

THEO. AUDEL & CO., 63 Fifth avenue, New York, have just published "Hawkins' New Catechism of Electricity." It is an excellent means to obtain a practical knowledge of the subject.

MR. ALFRED C. COURSEN is now associated with Mr. Edward P. Thompson and Prof. Wm. A. Anthony, at 5 Beekman street, New York, where he will assist them in their large business in American and foreign patents.

THE BEATTIE ZINC WORKS COMPANY, Reading, Mass., are kept busy in meeting the orders for their patent amalgamated, self-cleaning zincs and those who use them find them to be without scale and very efficient.

BILLINGS & SPENCER COMPANY, Hartford, Conn., carry in stock, commutator segments for all the standard makes of dynamos and furnish special sizes and shapes to order.

BRYANT ELECTRIC COMPANY, Bridgeport and Chicago, have just put on the market a new line of rosettes for which they claim special merits. Their new catalogue is now ready for distribution.

EDWARDS & CO., 144th street and Fourth avenue, New York, have lately introduced an ingenious new electro-mechanical gong. It is of much value for fire alarm use in factories, mines and railroads, as it is so constructed that it cannot fail to sound at the proper time.

THE CLIFTON MANUFACTURING COMPANY'S insulating conduit has been approved by the New York fire department and the National, New York and Boston Boards of Fire Underwriters.

H. L. CHINA COMPANY, Charleston, N. H., supply insulators, tubes, cleats, etc. They publish this week a letter from one of their old customers who pays a very high tribute to the quality and durability of their goods.

WM. H. WESTON & CO., 1307 Buttonwood street, Philadelphia, continue to manufacture switchboards, knifeblade switches, quick break switches and all fixings needed for their installation.

BIBBER, WHITE COMPANY, Federal street, Boston, Mass. have purchased stock and good will of Bibber, White & Co., and the New England Electric Supply Company, and are prepared to quote prices on supplies for the electrical and kindred trades.

SCHIFF, JORDAN & CO. say: "Do not write us unless you want absolutely the highest grade carbons."

FUEL ECONOMIZER COMPANY, Matteawan, N. Y., state that by their system a saving of 10 to 20 per cent. in fuel may be effected.

PECKHAM MOTOR TRUCK AND WHEEL COMPANY show a cut of their "extra long" truck with extension rods for long open cars.

HUGO REISINGER, 38 Beaver street, New York, supplies the "Electra" highest grade Nuernberg carbons for alternating and direct currents and also for enclosed arc lamps.

THE H. B. CAMP COMPANY, Aultman, Ohio, have sold over 5,000,000 feet of their vitrified clay conduit.

JAS. C. WORMLEY & CO., Marquette Building, Chicago, are allowing 10 per cent. discount on incandescent lamps for the next thirty days. They are also offering testing apparatus for 300 lamps for $1.50 cash with order.

THE CROCKER-WHEELER ELECTRIC COMPANY, 39 Cortlandt street, present a wonderful but by no means complete list of power plants they have installed aggregating over 8,825 horse-power. This company have made a careful study of electrically driven power tools and the plants they have thus equipped have been most satisfactory.

JAMES LEFFEL & CO., Springfield, O., build water wheels for heads of from 3 to 2,000 feet. Among their installations may be mentioned the plant of the Niagara Falls Hydraulic Power and Manufacturing Company, where 7,000 horse-power are developed at a head of 205 feet.

STANDARD PAINT COMPANY, New York City, it is needless to say, find the demand for their goods to be brisk.

THE H. P. BALL MANUFACTURING COMPANY, 101 Beekman street, New York, advertise switches and switchboards. This means everything in both lines.

THE BISHOP GUTTA PERCHA COMPANY, New York, say their motto is, "Nothing but gum," and good gum at that, making a specialty of meeting the most trying conditions.

THE METROPOLITAN ELECTRIC COMPANY, 186 Fifth avenue, Chicago, are selling an automatic pressure oil filter for $25, with discounts to the trade. Their catalogue containing 775 pages will be sent on receipt of 50 cents to cover expressage or will be included in a small order.

THE C. & C. ELECTRIC COMPANY, 143 Liberty street, New York, have brought out a motor (type 4P) for direct-connected elevator work and printing press driving. Some of its strong points are slow speed, efficient and rugged motive power and its adaptability whenever counter-shafting and belting are objectionable.

THE WARD-LEONARD ELECTRIC COMPANY. Hoboken, N. J., invite bids before purchasing theatre dimmers.

THE CONSOLIDATED INSULATED TUBE COMPANY John Hancock Building, Boston, Mass., invite prospective buyers to write for prices on their brass and iron armored conduit.

W. R. BRIXEY, 203 Broadway, New York, pronounces "Kerite" wires and cables the standard for all circuits.

WM. TAYLOR, 203 Broadway, New York, is ready to supply a full line of electrical goods, including lamps, incandescent and arc, switches, slate for switchboards, etc.

WILSON & WINKLER COMPANY, 779 Greenwich street, New York, do all sorts of repair work.

THE PERKINS ELECTRIC SWITCH AND MANUFACTURING COMPANY, Hartford, Conn., have brought out a new solid plate flush switch which is shown in exact size in their "ad" in this issue.

NEW YORK NOTES.

THE AMERICAN WAX AND PAPER MANUFACTURING COMPANY, 199 Franklin street, New York, are importers and dealers in pure ozokerite, carnauba and paraffine wax, etc., for insulating purposes. They guarantee their goods free from adulterations and will be pleased to mail samples and prices to any address on application.

JOHN SIMMONS CO., 106-110 Center street, New York, are headquarters for wrought and cast iron pipe, fittings, valves and supplies for steam, water and electrical engineering. Their establishment is one of the largest of its kind in this country. The John Simmons Co., are sole manufacturers of the Excelsior railway bracket, now one of the best and cheapest on the market for trolley use, etc.

THE BRISTOL RECORDING INSTRUMENTS.—We have received a circular from the Bristol Company, of Waterbury, Conn., giving the sizes of their well known and highly useful recording volt, ampere and wattmeters, giving detail information and dimensions which will assist in laying ont and designing switchboards where the Bristol instruments are to be used. The circular also gives excellent illustrations of the styles of terminals employed on instruments for heavy current. The demand for the Bristol recording instruments is so steadily on the increase as to make it necessary to send out this circular in anticipation of the needs of their customers. The company will be pleased to forward a copy of the circular with their catalogue to all applicants for the same.

NEW YORK STENCIL WORKS, 100 Nassau street, New York, solicit the electric trade for name plates. They are one of the oldest New York concerns in this line and do also model and experimental work, die sinking and general engraving.

THE ELECTRO-CHEMICAL STORAGE BATTERY CO., 34 Broad street, New York, report a steady and satisfactory growing business. Their storage batteries are giving perfect satisfaction. Prospects for business for 1897 are very promising indeed.

HAMERSCHLAG & CO., 26 Liberty street, New York, report business quite brisk. They are receiving orders along the entire line of their specialties, such as X-ray apparatus, small size motor transformers for charging batteries, dynamo brushes, etc.

ZIMDARS & HUNT, No. 127 Fifth avenue, New York, report selling a large number of their patent automatic switches for electric motors specially adapted for operating electric pumps. The price charged for this ingenious device is very inviting.

GOLDMARK & WALLACE, 29 Chambers street, New York, report business very satisfactory. They are offering a thoroughly reliable and well-made fan motor outfit and will take pleasure in mailing catalogue of same as well as of the "Eck" dynamos and motors for which they are the agents. Messrs. Goldmark & Wallace are also the United States agents for the well-known Koch woven wire brush, the popularity of which is growing very fast.

HAMMACHER, SCHLEMMER & CO., 209 Bowery, New York, carry a large and complete line of tools for electrical machinsts, also steel wire suitable for springs, switches, etc. Their patent steel wire is probably the best of its kind now on the market, well tempered and of extremely high tensile strength.

THE MENLO PARK MANUFACTURING COMPANY manufacture a superior medical battery in conjunction with their "Leader" dry cell, one of the most powerful and long-lived dry batteries known; the latter never burst or leak. These medical batteries, it is claimed, can be depended upon at all times and have been specifically prescribed by physicians of note. The Menlo Park Manufacturing Company manufacture also push buttons and binding posts. Their works are located at Menlo Park, N. J., with office at 631 Broad street, Newark, N. J., New York office 61 Fifth avenue. A catalogue will be mailed to any address on application.

THE STORAGE BATTERY SUPPLY COMPANY, T. D. Bunce, proprietor, 239 East Twenty-seventh street, New York, have recently fitted up several wagons of B. Altman & Co., Sixth avenue, New York, with their electric carriage lamps; they are giving first-class satisfaction.

THE FACTORY OF C. A. ECK, 157-161 Oraton street, Newark, N. J., is running busy on orders for his latest make of dynamos and motors. These are of Mr. Eck's own design and are of high efficiency. Catalogue mailed to any address on application.

THE GOODYEAR VULCANITE COMPANY, of 353 Broadway, New York, have long made a specialty of hard rubber goods for electrical and mechanical purposes. They have devoted particular attention to the manufacture of the long-handle and watch-case telephone receiver and their products also embrace phonograph tubes, hook insulators, magnet heads, battery cells, sounder and relay covers, cord adjusters, switch handles, and, in short, everything in electrical rubber. The company will be pleased to quote prices.

C. W. HUNT COMPANY, 45 Broadway, New York, issue an exhaustive catalogue on their coal conveying system suitable for electric light and electric railway stations. The "Hunt" conveyor system is widely known and is in use throughout the entire country. It is a thoroughly up-to-date mechanism. The C. W. Hunt Co.'s estimates and plans for their specialty embody the experience of 23 years of this work.

PATTERSON GOTTFRIED & HUNTER, LTD., 146 Center street, New York, have agents in all the principal cities of the United States for the sale of a general line of machinery, metals, tools, hardware and supplies which they carry. They are also agents for the Shaw patent compression flange coupling. Catalogues will cheerfully be mailed to any address on application.

E. H. KELLOGG & CO., 243-244 South street, New York, furnish oil and lubricants to a large number of electric plants in this and foreign countries. They are one of the oldest and largest oil house in existence, and have branches in London, Liverpool, Bremen, Hamburg, Bombay and Calcutta.

D. S. PLUMB, 24 Boudinot street, Newark, N. J., is busy on clock work mechanical movements and recording devices used in the electrical and other lines. He manufactures counters for water, gas and electric meters and will be pleased to make estimates from models or drawings.

UHLING, STEINBART & CO., LTD., 63 Mulberry street, Newark, N. J., report a good trade in their pneumatic pyrometers. These instruments record up to 3,000 degs., and are now being used in the largest plants in the country.

KEUFFEL & ESSER COMPANY, 127 Fulton street, New York, will be pleased to mail an exhaustive catalogue to any address on application. They are the largest house in this country importing, dealing in and manufacturing drawing materials and surveying instruments.

JOHN W. FERGUSON, builder and general contractor, 253 Broadway, New York, is open to undertake the erection of electric light and railway plants or any class of buildings. Mr. Ferguson is busy with large contracts at the present time. In the electrical industry he can refer to his work for the Edison Electric Illuminating Company, Paterson, N. J.; the Steinway Railway Company, Astoria, L. I.; the Bergen County Traction Company, Fort Lee, N. J., and many more, the result of his labors.

MR. ELMER P. MORRIS, whom everybody in the electric railway field knows and who knows everybody, has been appointed Eastern agent for the McGuire Manufacturing Company, of Chicago, Ill., whose trucks for electric cars—and any others, if such now exist,—he will be glad to furnish or to answer inquiries about.

MESSRS. WM. BROWNE & SON, Bank street, Newark, N. J., have contracts to wire the Camden (N. J.) armory, the Lang Company's tannery, the Newark City National Bank, Roe & Conover's warehouse, Senator Smith and Chas. H. Case's residence at Newark. The Consolidated Electric Supply Company have the contract for all the supplies used for the above work.

THE LATE HARVEY L. LUFKIN. The directors of the Crocker-Wheeler Electric Company have adopted a set of resolutions in regard to their late Manager of Sales, Mr. H. L. Lufkin, expressing deep regret at their loss and a high appreciation of him personally and in his business capacity.

WESTERN NOTES

ARMORITE.—The Armorite Interior Conduit Company, of Detroit, Mich., write us that they are very busy and have all they can do to keep up with orders. Among recent orders reported by Mr. J. F. Cummings, general manager, is a large one for the Hotel Henry, Pittsburg, a magnificent new building, which is to be tubed throughout with Armorite, and for which the material is now being shipped.

THE ELECTRIC APPLIANCE COMPANY look back on the Christmas season just passed, as a particularly satisfactory one, not only for the reason that it represents the beginning of their sixth business year, but also on account of the very satisfactory way in which the orders came in during the month of December, at which time they report that business seemed to take quite a jump.

AS AN INVESTMENT.—Under this title, the Garton-Daniels Electric Company, Keokuk, Ia., have issued a dainty little brochure which demonstrates the economy derivable from the use of their lightning arresters. It gives a list of several street railway and lighting companies that use this excellent appliance.

K. McLENNAN & CO., of Chicago, Ill., the sole manufacturers of the celebrated "Gale's Commutator Compound," stated to a representative of this paper that the sales of their compound during the past year have more than trebled those of any previous year; that wherever "Gale's" has been tried it becomes readily adopted. At this time more than three-fourths of the power plants and central stations have adopted its use; and it is now universally conceded to be a "dynamo necessity." To the isolated plants as well as the central stations and power plants, which have not already tried this compound, they will continue to send upon request a free sample stick. They state further that this compound has been equally well received in Canada and Mexico as well as in Europe, whither recent large shipments have been made, and that requests for samples have been received from nearly every section of the civilized world.

The Electrical Engineer.

Vol. XXIII. JANUARY 13, 1897. No. 454.

ELECTRIC LIGHTING

THE LAUNCESTON, TASMANIA, ELECTRICITY SUPPLY WORKS.—A WATER POWER PLANT.

It was nearly ten yeas ago that the project of supplying electricity to the town of Launceston, Tasmania, was first broached, but it was not until 1889 that the project took definite shape. It was then decided by the City Council, on the advice of their engineer, to utilize the power of the South Esk River, a stream which rushes in a series of cataracts for miles above the gorge, where it joins its waters with those of the North Esk, to form the River Tamar.

THE HYDRAULIC WORK.

Various schemes were proposed for bringing the water from the upper level to the wheels, and the engineers finally decided on boring a tunnel in lieu of iron pipes, as at first proposed.

The grade of the tunnel is 1 in 110, calculated to give a velocity of about 10 feet per second, and therefore a discharge of about 11,780 cubic feet per minute; but as by Parliamentary restrictions only two-thirds of the water flowing in the river is to be made use of, that quantity, equal to 10,000 cubic feet per minute, is all that can be depended on during dry summer weather. The resulting horse-power, taking 10,000 cubic feet per minute as a basis, is 1,562, at 75 per cent. efficiency of turbine, and costs therefore £8 10s. per horse-power, a rate which compares very favorably with work in any part of the world.

From the screening chamber the water, after straining, flows through a wrought-iron sluice gate opening, and by a pipe line is conveyed to the power station, as shown in plan and elevation in Fig. 1. The pipe is of wrought iron with flanged joints, is ¼ inch thick, and for the first 82 feet is 5 feet in diameter, the remaining 121 feet being 4 feet in diameter. The lower end is expanded into a bell mouth, 6 feet by 2 feet 6 inches. The latter conveys the water to a wrought-iron receiver 80 feet long, which extends along the back of the power house, and is supported in similar manner to the pipes. The central portion, 41 feet in length, is 6 feet in diameter, and is of wrought iron ⅜ inch thick; the two end portions being 3 feet in diameter and ¼ inch thick, all being held back by 1½-inch anchor bars. The receiver is fitted with four 4-inch dead weight safety valves.

From the 6-feet section the water is led into the building by means of four 2 feet 4-inch pipes, and from the 3-feet sections by six 12-inch pipes, though only three of the former and five of the latter are at present in use, one of each being left for future extensions. The water from these pipes is taken directly to the turbines, draft tubes being made use of to ensure at least 110 feet of working head.

THE POWER HOUSE.

The power house, shown in Fig. 2, is situated above highest known flood mark on the river bank. It is built of the local basalt on concrete foundations, and with galvanized iron roof; is 105 feet by 24 feet in the clear, with a central bay of 40 feet, which is 6 feet wider. The height of the wings is 15 feet, and of the center, 22 feet; to the wall plate in each case. The tail race extends nearly the entire length of the building, is 9 feet wide and 12 feet deep, and was excavated in the solid basalt. It is arched over with concrete, on which are bedded the girders to which the turbines and other machinery are bolted.

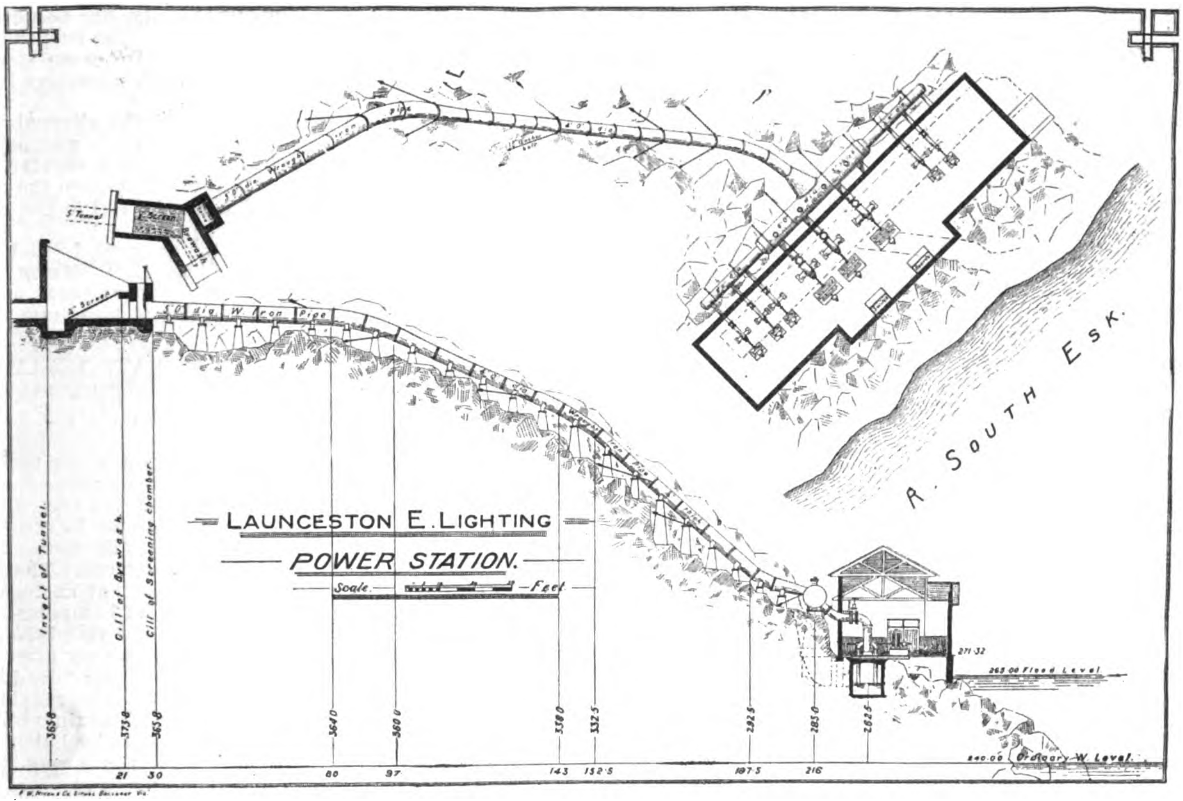

Fig. 1.—The Launceston, Tasmania, Electric Light Station.

TURBINES AND DYNAMOS.

There are eight turbines fixed and at work, all of the Thomson vortex type, fitted with the Murray hydraulic governor. They are adapted for a fall of 110 feet, and arranged for coupling direct to the dynamos. The outer case of these turbines is of cast iron, and the revolving blades are of brass. The fixed guide blades are of Delta metal, and are movable for adapting the entrance orifices to any quantity of water below the full supply. The wheels work vertically, and the draft pipes are fixed so that part of the fall acts by suction. They were made by Messrs Gilbert Gilkes & Co., of Kendal, England. Five of the turbines drive arc light dynamos at 800 revolutions a minute, at which speed they each give 21 horse-power. The other three drive alternators at 460 revolutions a minute, and each gives 158 horse-power.

The arc light dynamos are of Siemens Bros.' manufacture (their H. H. D. type), and give a constant current of seven amperes, and an e. m. f. of 1,750 volts when running at 800 revolutions a minute. They are driven direct by the turbines.

The alternators used are of the Siemens' W type, having revolving disc armatures, each of which has 24 coils, and revolves at a speed of 460 revolutions per minute, when the output from the alternator is 100 kilowatts at 2,000 volts. The alternators are connected directly to the turbines by means of a flexible coupling.

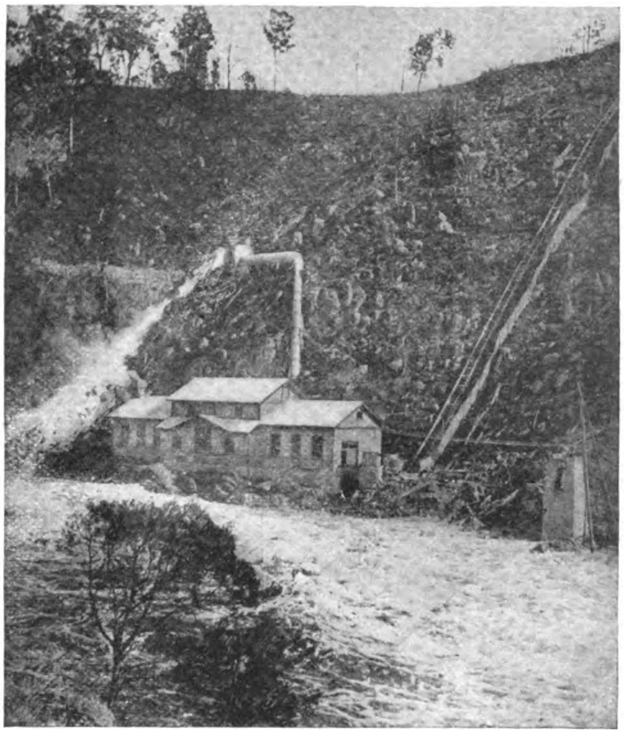

Fig. 2.—View of Launceston Electric Light Station.

DISTRIBUTION.

The engineer's plan was to distribute the electricity from a station conveniently situated for the purpose in the city, bringing the energy from the generating station by means of insulated cables suspended to poles, in as direct a line as possible. This line was the first work undertaken by the contractors. Substantial towers were constructed at both sides of the river, between them the leads were carried across the river, and on to the distributing station, a distance of about two miles; there they were connected through lightning arresters, and other apparatus, to the switchboards. From these switchboards the distributing mains pass out and along the streets in all directions over the city, the leads carrying the continuous current to the arc lamps which illuminate the streets, and those carrying the alternating current to transformers, where the current is reduced to the low voltage necessary for use in the incandescent street lamps, as well as those which light up public and private buildings.

Another peculiarity appears in the arrangement of the mains carrying the alternating high tension current. As this current was to be used for two purposes—street lighting in the outlying parts, and private lighting and power work, each of which might be used at times the other was not required—the leads from one pole of the alternator, instead of being one wire, are of two separate wires insulated from each other; the two being equal in conductivity to the one wire which forms the return to the alternator. Then the transformers for the street lamps are fitted between the return wire and one of the two leads, the transformers for private lamps being between the return and the other of the two leads. By this means, only the energy required for the street lamps, when they alone are wanted, and for private lighting when the street lights are not required, will flow from the alternators. By this means too, the very important desideratum, the being able from one point in the city to light up and turn out all the street lamps, is secured. Switches for accomplishing this are provided at the distributing station.

The transformers used about the city are of capacities varying from one to eight kilowatts. They are of the Siemens' double magnetic circuit type, consisting of Siemens' special stamped core plates slipped into a bobbin, on which the two coils are wound. They are arranged to transform from 1,900 to 112 volts at a frequency of 92, and at full load have an efficiency of over 98 per cent. They are enclosed in iron watertight cases.

The arc lamps, of which there are 120 fitted about the streets, are of the Siemens' "band" type, take seven amperes of current, and burn for sixteen hours without being re-carboned. They are placed inside lanterns fixed on top of poles which stand in the middle of the streets. The lanterns were made by the contractors to the superintending engineer's design, and are glazed with special dioptrical glass, which, while diffusing the light without any considerable loss, makes the lamps pleasant to look at, being free from that glare so frequently present with arc lamps. The incandescent street lamps, which are nearly all of 50 candle-power, are suspended under iron enamelled reflectors fixed to iron brackets screwed to the poles.

The distributing station stands on a block of ground at the intersection of Bourke and Canning streets. It is a neat brick building with central wooden tower, to which the wires are brought, and from which they pass down to the switching apparatus below. The building is divided into a switching and testing room, a workshop and a store-room. There is also provision for a set of arc-lamp regulating stands, fitted with ruby-glass doors.

The heavy leads from the generating station, as well as those carrying alternate current about the city, are suspended from steel wire tied to porcelain insulators. The suspending clips, which attach the cables to the steel wire, were specially designed for this work, and made by the contractors in Launceston.

Within five months of the starting of the alternators, nearly 5,000 incandescent lamps had been installed, and applications for the light were being received with such regularity that it seems clear that no long time will elapse before the additional alternator and turbine, for which room is left in the generating station, will be required.

The entire electrical equipment was carried out by Messrs. Siemens Bros. & Co., of London. Mr. K. L. Murray acted as superintending engineeer for the electrical plant and Mr. C. St. John David for the tunnel, pipes and buildings.

THE EVOLUTION OF THE ISOLATED ELECTRICAL PLANT DURING THE LAST FIFTEEN YEARS.—II.

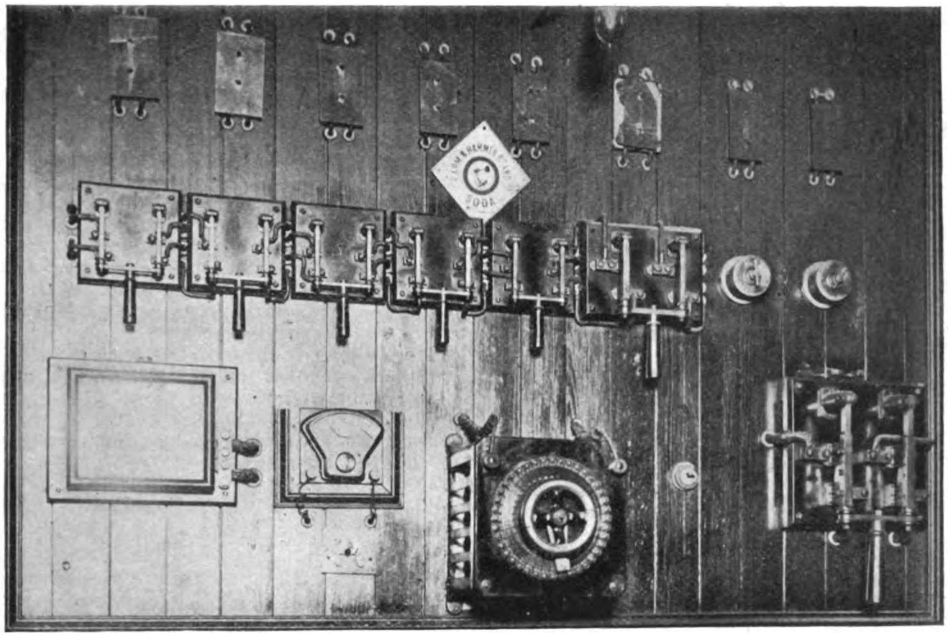
BY CHARLES HENRY DAVIS, C. E.

SWITCHBOARDS.

These were practically unknown when the rheostat was placed on the machine itself and later was hung on the wall, while the voltmeter rested on a wooden shelf and the ammeter was placed where the main circuit left the dynamo room; these latter instruments were little more than indicative of a rise or fall in pressure or current. The writer remembers testing some old ammeters somewhat as follows: Current was started from zero, increased to 25 amperes and multiples thereof, according to the laboratory standards; at each point of rest (which was reached at times only after considerable delay, the instruments not being of the "dead beat" variety), a pencil mark was made; when the maximum was reached the operation was reversed and again pencil marks made, these often varying from the others by half an inch on a total scale of eight or ten inches; the mean was struck and the scale scratched ready for shipment.

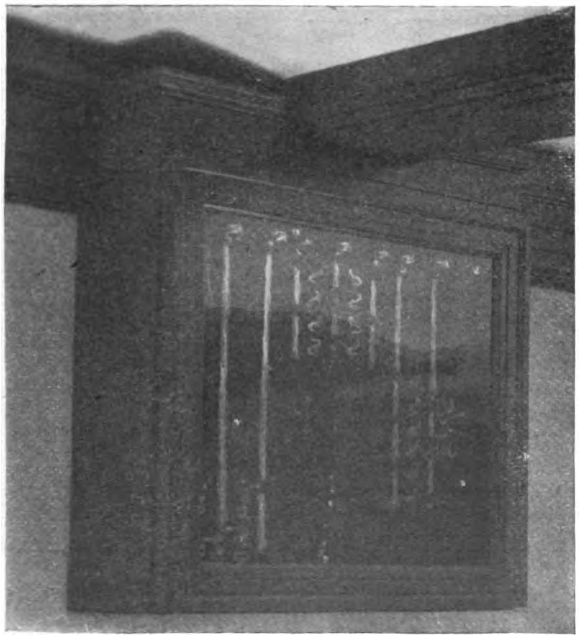
The switchboard of to-day was due to the development in methods of wiring; at first only one or two circuits ran from the dynamo room while now the entire system is controlled from this point by the use of elaborate switchboards of slate or marble set in wood or iron frames. The first step was to use wooden boards upon which were mounted, on their own wooden bases, switches, voltmeters, ammeters, rheostats, etc. These boards were often made skeleton and their liability to catch fire was great; from this risk grew the method of mounting rheostats in iron boxes and switches on slate bases, the next step being the placing of these directly upon the slate switchboard specially drilled for the purpose. The old boards were small affairs while those of to-day are often 20 feet long with great skill shown in their arrangement, design and workmanship; these boards are often arranged to take current from the street on a three-wire system and from the dynamo on a two-wire system.

The old rheostats were very large, clumsy arrangements mounted on wood and made of iron wire, later of German silver, while those of to-day are small compact iron boxes or plates of porcelain and are fireproof. Old time switchboard connections were made of insulated wire run in a promiscuous manner; later copper rods were used and to-day a combination of these with brass or copper bars mounted on hard rubber.



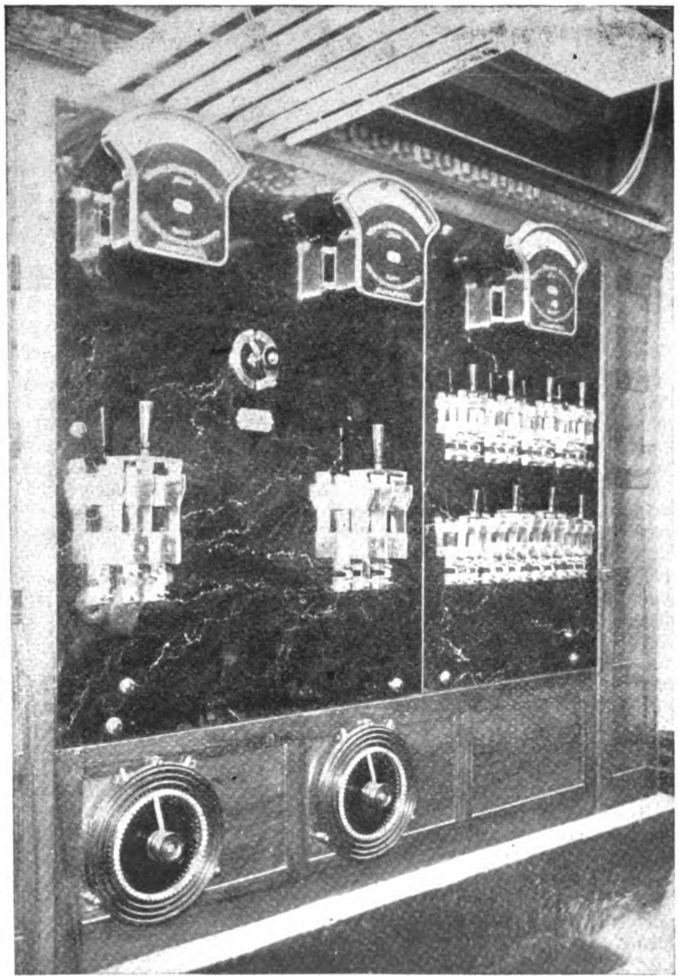
Old Style Switchboard.

In switches and their uses we see the change from vertical and single pole side throw and plug switches to the double and three pole knife blade switches such as those for dynamos and their equalizing connections or to break their fields; double throw switches to change dynamos, or circuits, or from two to three wire systems; from front to back connected switches and all the other endless varieties.



Old Style Panel Board.

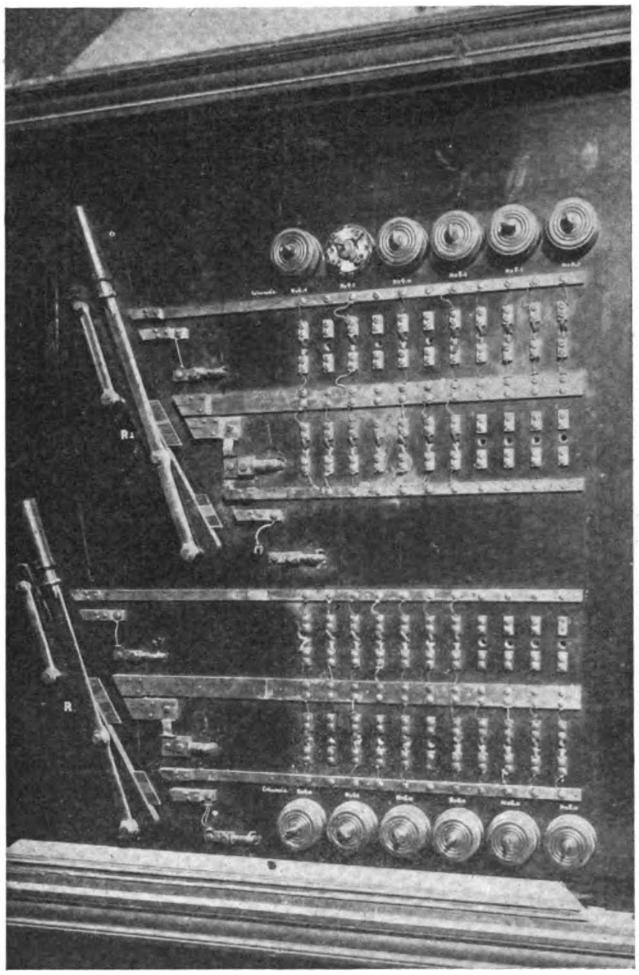
In indicating and recording devices we have passed through the various stages of instruments with angles marked on the scales to be figured, by a table, into volts and amperes; instruments that took a minute or more to come to rest, to those that are "dead beat;" instruments wherein the heating effect prevented their constant connection to the circuit, to those that are in shunt and have illuminated dials and artistic design; while the recording wattmeter keeps a constant record of the power developed which was formerly only obtained by frequent readings of inaccurate volt and ammeters. The engravings give some views of old and new boards.



Modern Switchboard.

WIRING.

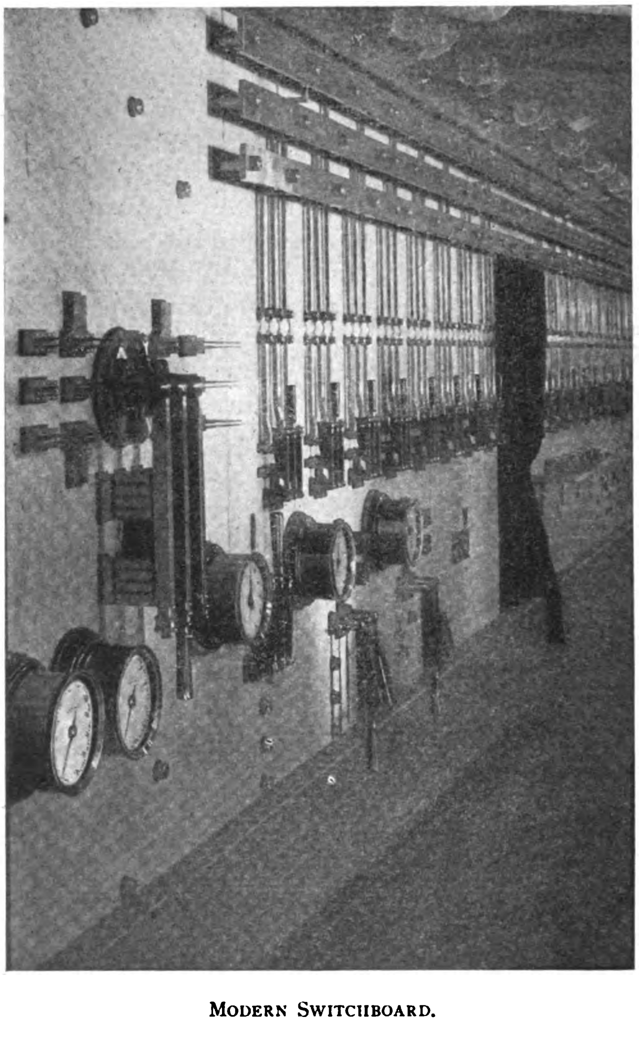
The changes and developments in our wiring systems have mostly come from increase in the size of the plants installed and the greater care required in reducing the fire risks. Wires were first run exposed and supported on wooden cleats, iron hooks, etc.; then in mouldings and on glass or porcelain. These wires were the famous and later "deadly" "underwriters," which are discarded but now on the high road to being again required by our insurance boards. When wires were to be concealed they were lead incased and run in plaster under tile floors, etc., with the result of perpetual grounds and recurring burn-outs. Later wires were covered with rubber or compounds of gutta-percha, some taped, some braided and these were imbedded in plaster walls with but little better results. When "underwriters" wire was condemned for concealed work and mouldings the manufacturers placed upon the market the so-called "weather-proof" and "weather and fireproof" which only differed in the compound being a hydro-carbon product and more easily burned in the first case, and in the second, the inside was weather-proof and the outside fireproof, substantially another name for "Underwriters." The next step was paper, canvass or composition tubes through which the wires were drawn for all concealed work, while the final step has been the use of gas piping lined with paper or composition as an insulating material with some talk of using plain iron piping. The use of tubes has brought with it the placing of positive and negative wires together; in the case of paper tubes, for branch circuits carrying a small current, while with iron armored tubing both polarities are run together up to 100 amperes.



Model Panel Board.

In the distribution of current the old time method was to run a main wire from the dynamo, reducing it in size at various points; then a feeder to the center of distribution with mains the same size their entire length. As control from the dynamo room was developed, partly due to increase in the size of plants, separate mains were run to each floor, or group of floors, the same size over their entire length. To-day combinations of all are used according as they produce the most uniform potential at the lamps. In the distribution wooden cut-outs were employed entirely until earthenware and procelain forced their way into use owing to superior protection against fire; these were placed along the feeders, mains or branches, as circumstances required, and were at first uncovered and exposed; later they had mica or porcelain covers and were grouped together. This grouping or "pocket system" led to the use of slate distribution boards which are now universally used in the best construction and are similar to small switchboards, with or without switches; these are often enclosed in slate-lined boxes. The writer believes that these slate distribution boards or "panel boards" were first used as a system in the Pennsylvania Mutual Life Insurance Building, Philadelphia. One of the engravings shows these crude panels as they were then made, while some of the latest are shown in the other engravings; the writer also believes that the slate-lined box was first suggested and called for in specifications prepared for the Hon. Whitelaw Reid's house in Westchester County in the winter of 1889-90; this plan, however, was never carried out.

The change from switches with wooden bases, poor contact and lack of quick make and break, single pole and light mechanical construction, to those which are fireproof, substantially and electrically first-class, is well known. Porcelain cleats, the running of wires between insulators without tie wires, the avoiding of all soldered joints in runs, the use of junction boxes and tubes are some of many improvements in our wiring systems. A marked change has taken place in the manufacture and use of fuses, the tendency now being to avoid their use whenever possible, to have them with metal terminals and standardized and in many cases displaced by circuit breakers.



Modern Switchboard.

ELECTRIC TOWING IN GERMANY.—It is stated that electric tow-boats are about to be placed on the River Spree, near Berlin, where for a distance of eight miles the ordinary barges cannot use sails, owing to a large number of low bridges. The trolley system will be used.

POWER TRANSMISSION

A CROCKER-WHEELER ELECTRIC DERRICK IN BROOKLYN, N. Y.

An illustration, Fig. 1, is shown herewith of a very interesting and effective derrick and hoist installed by the Crocker-Wheeler Electric Company, at Ampere, N. J., in the yards of Post & McCord, building contractors, etc., Newtown Creek, Brooklyn, N. Y., who have a large plant of their own for electric light and power. From that plant the derrick is supplied with current by means of a long run of underground lead covered cable, which leads into the derrick or crane. There is an ingenious contacting arrangement by means of which the derrick as it swings around gets its current without interruption. This device is placed under the power house shown in the cut. This house contains a 10 horse-power Crocker-Wheeler motor, with their automatic electric strap brake of the pivoted field type familiar to our readers. The arrangement is shown in Fig. 2. The little house above the larger one contains a 3 horse-power motor also fitted with automatic electric brake. The lower motor does the hoisting; the upper motor runs the rack, or trolley travel. A motor of from 3 to 5 horse-power is now to be installed to turn the crane around, that having been done hitherto by hand. In the lower house there are two controllers of mill or street car type, one for each motor. One man manipulates the entire combination, standing between the two controllers, one being held in his left hand and the other by his right.

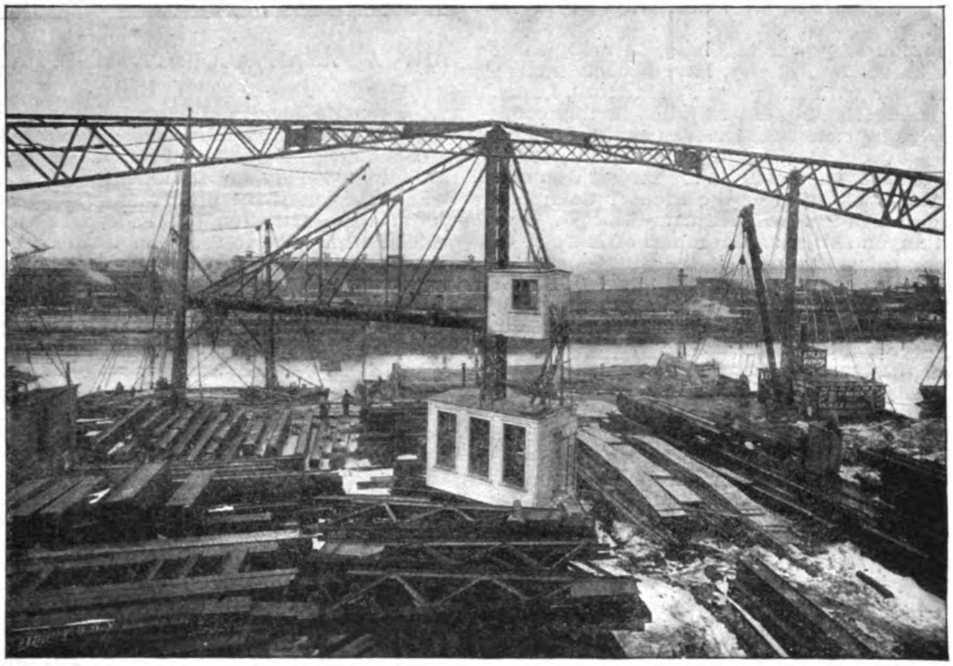


FIG. 1.—10-TON DERRICK CRANE AT IRON WORKS OF MESSRS. POST & McCORD, BROOKLYN, N. Y.

One Size 10 C.-W. Single-Reduction Motor on Hoist and One Size 3 C.-W. Motor on Trolley Travel.

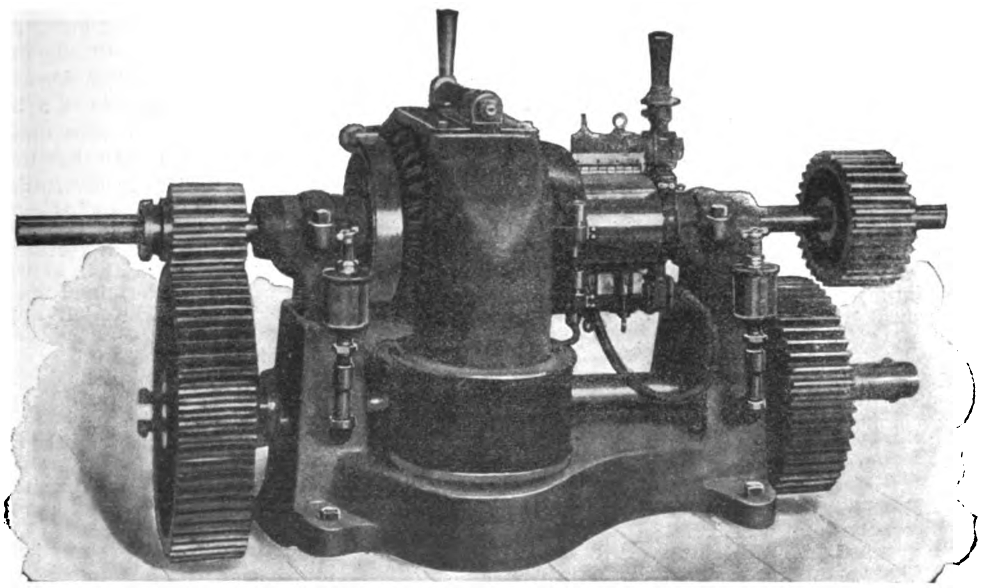

FIG. 2.—SIZE 10 C.-W. AUTOMATIC BRAKE MOTOR.

With Countershaft Through Base of Pedestals with Changeable Gears to Give Two Speeds.

This appliance has been in constant and successful use at Newtown Creek for two years loading lighters on the creek with building material. There is also a similar outfit at the entrance of the works, this being used for loading trucks.

The voltage of the system is 230. The generating plant is of Crocker-Wheeler make, consisting of one 80 kilowatt and one 60 kilowatt generator, for light and power purposes.

RECENT ADVANCES IN POWER TRANSMISSION.

By JOHN McGHIE.

THE long-distance transmission of power was seriously handicapped by the unavailability of the direct current as far as generation was concerned, and equally by that of the alternating current at the motor end. And not until the development of the alternating current multiphase system and the creation of the induction motor had become an actual fact did long distance power-transmission really rise above the horizon of the practicable. From the moment we became familiar with the multiphase system, the work of introduction became child's play in comparison with that with which we had struggled before.

Since 1892, transmission of power involving in many cases outlays of very large amounts of money, have become numerous. Starting in that year with the plant at Hartford, Conn., the first multiphase transmission plant installed in this country, in which the power is transmitted eleven miles, I find a succession, steadily growing in number and capacity each year, until we reach, in 1896, what will be the largest commercial transmission in the world, that of the Pioneer Company, at Ogden, Utah, which when finished will carry the power of the water of Ogden Canyon as far as the mines of Mercur, 60 miles distant. The great developments of the past four years in the electrical field, both from the commercial as well as the technical standpoint, have nearly all been made with a view to meet the demand which an earnest campaign of education has raised in the power transmission field. We have seen brought into existence the increasing and reducing transformer of very large capacity, cooled by air currents; the rotary converter, which converts alternating current into direct and which has given to our present street railway systems a means of economically feeding current to their most distant sections; the lightning arrester for high-tension work; the multiphase generator of which examples exist which deliver current direct to the wires at high voltages only a few years back deemed impossible; and lastly the induction motor, that beautiful creation which does its work with all the precision of the direct current motor, while having no commutator, no brushes, no moving contacts, nothing, indeed, but three wires attached to the binding screws.

But the transmission of power by no means implies the necessity of long distance. In mill and mine practice, while the direct current system is by no means discarded, the multiphase system is finding a large place. The equipment of a transmission plant for mine or mill, distance being slight, differs in no way from the long distance plant, excepting in the absence of the raising and reducing transformers, and in the modified subsidiary apparatus. The same advantages are present.

At Columbia, S. C., the entire machinery for a huge cotton mill is driven by multiphase apparatus; similarly at Taftville, Conn., and instances are multiplying fast all through the country. In mine work, the multiphase system has only recently been introduced, yet it is receiving a gratifying reception, thanks to the propaganda, which, let me not omit to say, has been very largely carried on by the electro-technical papers, The Electrical Engineer by no means the least prominent.

The benefits which the employment of electricity as a motive power confers upon mine and mill operation, have been too frequently set forth in your columns, to warrant digression now. Suffice it to say that it may be epitomized in increased and improved output; reduction in cost of operation and maintenance expense; better physique and morale of operatives, and a general pervasive satisfaction.

Some idea may be gathered of the growth of the power branch of the great electrical industry by an examination of the following figures, given in horse-power instead of in dollars, to avoid erroneous comparison. They are taken from the published figures of only one of our largest companies. Up to 1892 the total horse-power of the apparatus for purely power purposes sold by this company, amounted only to 13,719 horse-power. In 1893, the total sold exceeded that of all years previous by 5,000 horse-power, the total reaching 18,762; in 1894, the total for that year reached 42,379 horse-power, while in 1895, not less than 46,727 horse-power had been called for. The year 1896 has been universally conceded the nadir of business depression, yet I feel warranted in saying that if the outside observer had been limited to conclusions drawn from the amount of power apparatus sold he would have classed it as a fat year among fat years. Between Jan. 1 and Dec. 31, quoting from the same source, the apparatus sold for power transmission and power utilization purposes, amounted to the very respectable total of 75,000 horse-power.

Nothing further than the foregoing need be said to show the important place now occupied by electric power in the industry. If to the above figures could be added the results of the work of the other concerns manufacturing electric power apparatus, the total would probably assume proportions likely to tax the credibility of your readers. Meanwhile, all the signs point to a still larger extension in this branch of the business, and they are of the character that augurs realization.

MISCELLANEOUS

HOW A FATAL ACCIDENT HAPPENED IN PHILADELPHIA.

A coroner's jury in Philadelphia has rendered a verdict of accidental death in the case of Joseph Muchenrider, the 15-year-old lad who was killed by touching an electric wire in the fire box at Second and Callowhill streets. Andrew Gallagher, the companion of the unfortunate lad, stated that he and the victim were attracted by the sparks coming from the box, which had set fire to the pole. Some one in the crowd of bystanders suggested that one of the boys turn in an alarm. Joseph stepped up to the box and touched the handle and instantly fell lifeless to the sidewalk.

Lineman McDugal, of the Electrical Bureau, said that the trouble was caused by two electric light wires coming in contact with a guy wire, which was fastened to the pole on which the fire box was placed, and to another pole on the opposite side of the street. The insulation on the electric light wires was worn off and the current was conducted to the guy wire and through that reached the metal tubing in which the alarm box wires are incased. In this manner the box became charged.

Several expert witnesses testified that the only way in which electric wires could be placed to insure safety is to have them placed underground. The jury recommended that the city councils pass an ordinance compelling all electric lights and telegraph companies to place their wires underground.

ELECTRICITY IN NAVAL LIFE.—XIII.

BY LIEUT. B. A. FISKE, U. S. N.

HORZIONTAL BASE POSITION FINDER.

IF the ground in the vicinity of the water is not high enough to offer a sufficiently long vertical base line for a depression finder, it becomes necessary to use a horizontal base. The solution of the problem of so employing a horizontal base has been attempted during many years, but, so far as the writer has been able to ascertain, the only system that has done it successfully is the one here described, in which telescopes located at the opposite ends of a base line carry contacts which sweep over arcs of wire that are connected together in the same way as in the range finder just described. The position finder referred to in the Italian report, of which an extract has just been given, is of this character. Another form is shown diagrammatically in Fig. 40, in which—

A B represents the parapet of a fortification. The distant object is supposed to be located at C, and it is the position of this object which is to be determined upon a suitable chart, D, on which the fortification line A' B' appears on a reduced scale.

E is an arc of conducting material.

F is a telescope or alidade arm pivoted at one end at F', with its free extremity moving over and making contact with the arc E.

G is an arc similar in all respects to the arc E and located in suitable proximity to the chart D.

H is an arm pivoted at H' and having its free end sweeping over and making contact with the arc G and carrying a pointer I.

a b c d are members of a Wheatstone bridge connecting the arcs E and G.

e is a loop including the battery, and f the loop including the galvanometer g.

It will be obvious that when the arm H is set upon its arc G at the same angle to the line H' F' as the arm F upon the arc E, then the bridge will balance, and the galvanometer will indicate zero, and hence, inasmuch as the telescope F points to

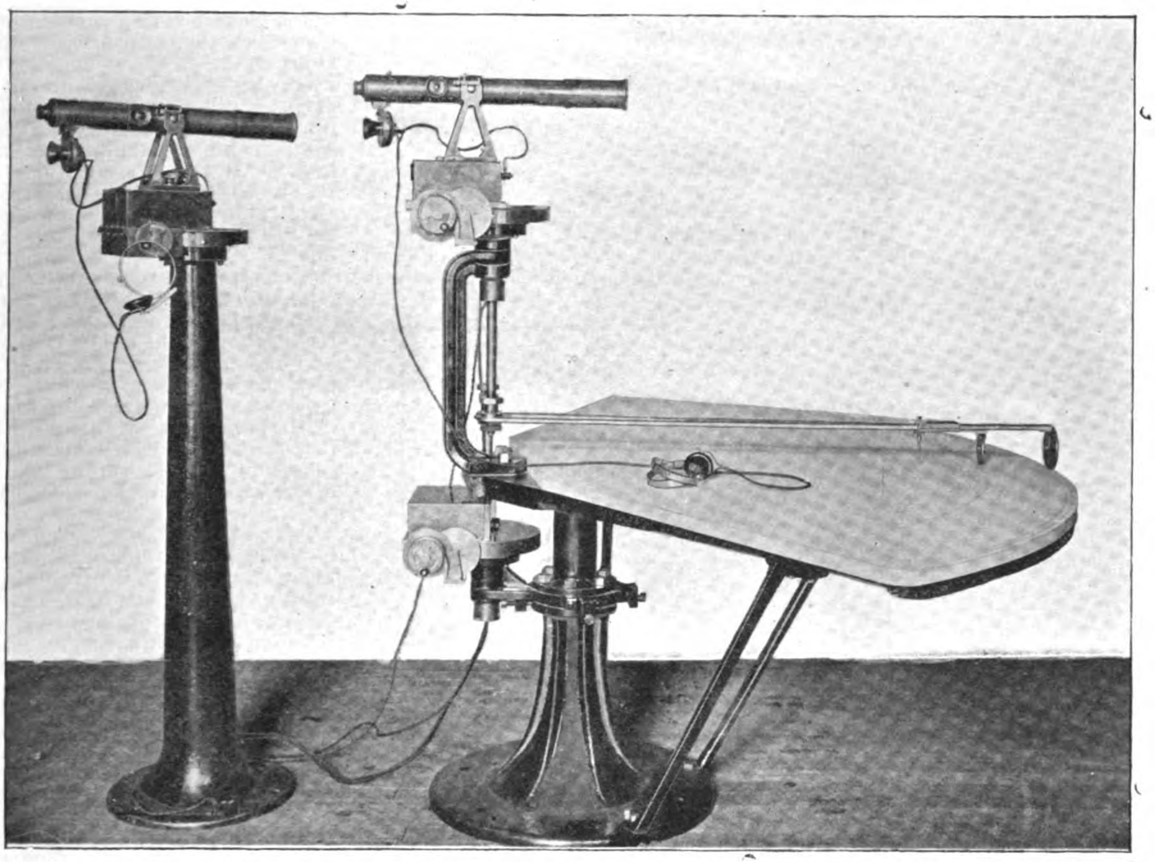

FIG. 41.—POSITION FINDER.

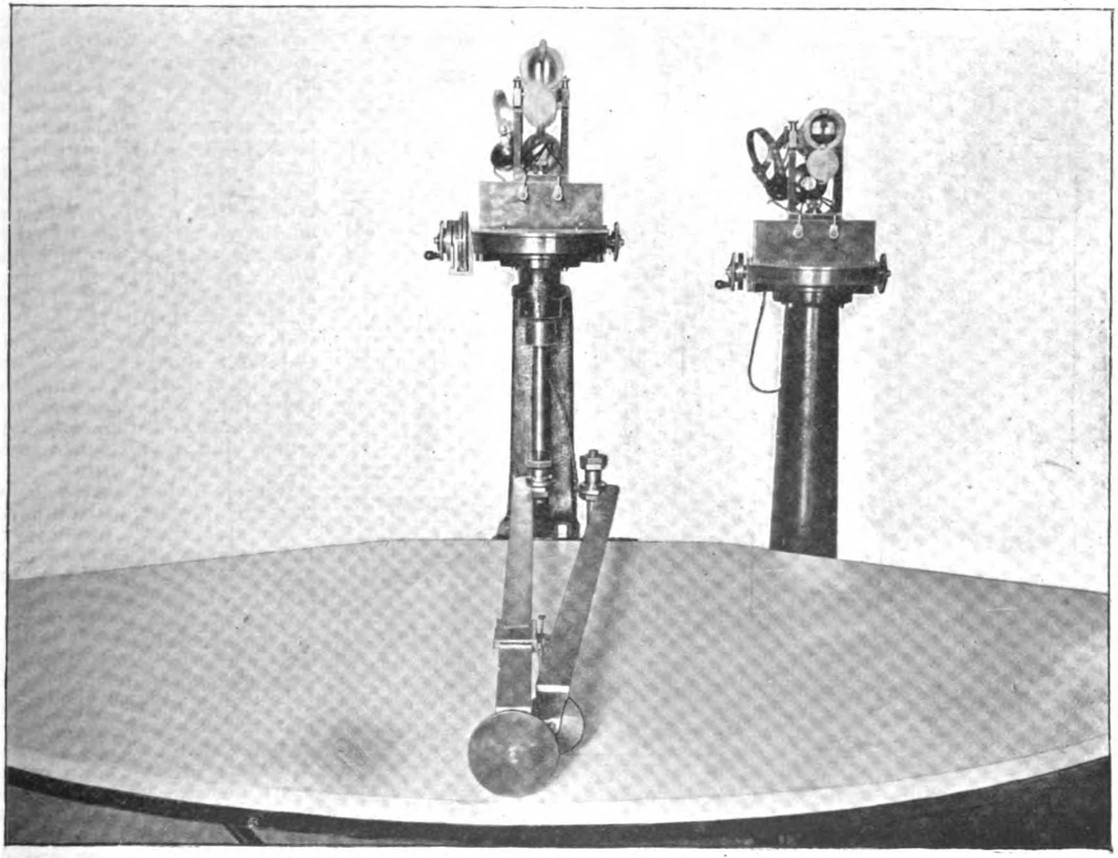

FIG. 42.--POSITION FINDER.

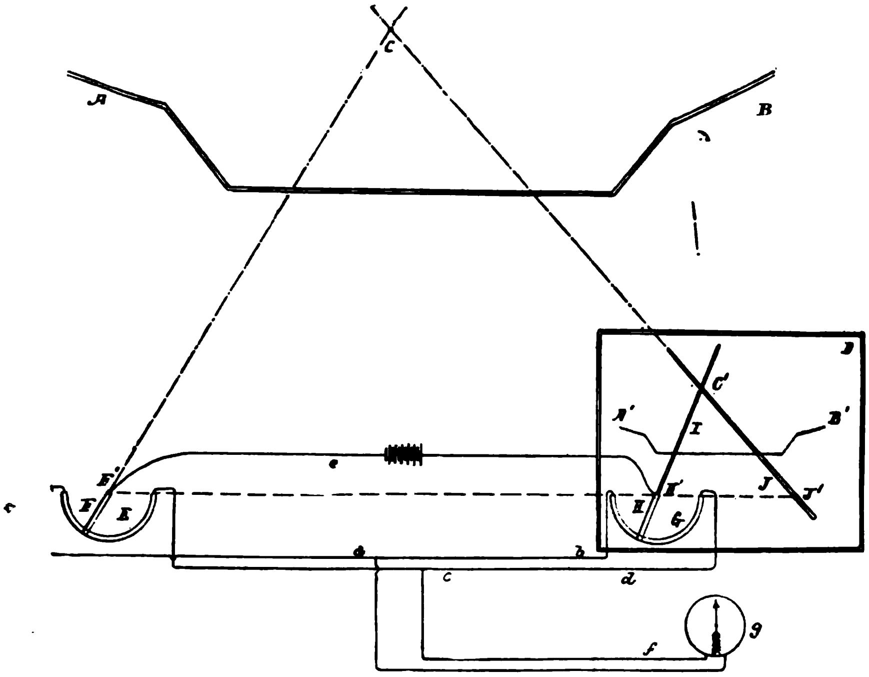

FIG. 40.—POSITION FINDER.

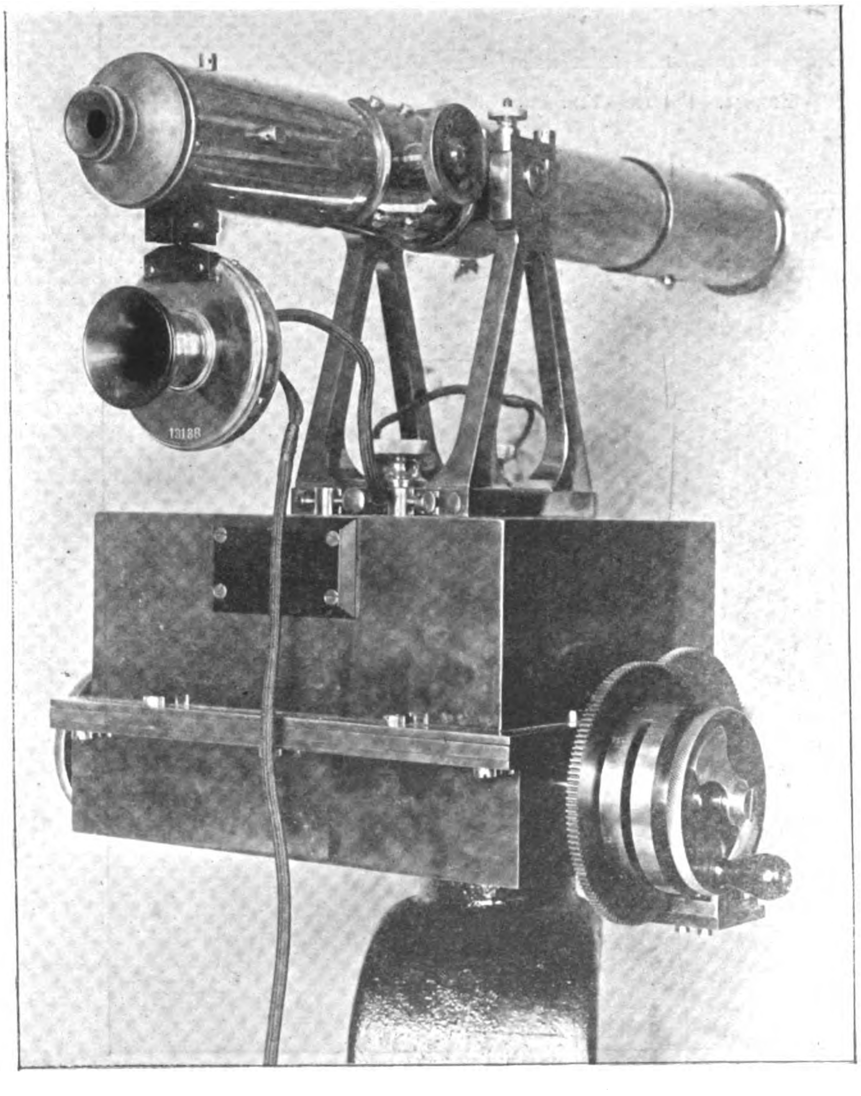

FIG. 43.—POSITION FINDER.

the actual object C, the arm H will point to the corresponding position of the object C or C' on the chart D. Pivoted upon the chart D at J' is an arm J, which arm may be provided with a telescope or alidade so that it may be directed upon the object C. The arm J is long enough to make intersection with the arm I. If then the arm J is trained directly on the object, inasmuch as the line H' J' joining the pivots of the arms I, J on the chart D corresponds to the base line F' J', extending between the distant stations, and as the angle C' H' J' equals the angle C F' J', it follows that the intersection of the arms I and J at C' indicates the position of the object C upon the chart D. The chart being drawn to scale, it is easy to recognize at a glance both the direction and the distance of the object C.

The latest form of this position finder is that installed at Fort Hamilton, and represented in Figs. 41, 42 and 43. The larger of the instruments is fitted with a plotting table as well as a telescope.

The resistance wire for each instrument is wrapped in a spiral around an insulating cylinder instead of being laid in the form of an arc, and differs from the new form of range finder principally in the addition of the plotting table. The operation of using it is much the same as the operation of using the earlier form of position finder just described. The observers point their telescopes so that the cross wires rest on the mast or funnel of the enemy's ship above the smoke. The reader at the plotting table, usually an officer, keeps moving the electrical contact of his instrument so as to keep the galvanometer needle always at zero, thus maintaining the corresponding pointer always in parallelism with the telescope at the distant station. The reader and the observers have telephone receivers on their heads and long distance transmitters on the telescopes; so that they are in constant communication. As soon as each observation is made the officer orders "rest," and both observers cease observing for awhile. At the end of twenty seconds the officer orders "mark." The observers again sight their telescopes on the target and keep the cross hairs exactly on the mast until the officer, at the end of ten seconds, again orders "rest." The officer now notes the intersection of the pointers and marks it on the chart by a spring pencil, connects it to the position just preceding by a short line, and prolongs this line to an equal distance beyond the last point. The end of this line is clearly the position which the ship will probably occupy at the end of the next thirty seconds, and it is this "predicted position" which is signaled to the guns. But the frequency of the observations and the length of time over which the prediction extends, may be made to vary at will.

With a little practice the work of plotting and predicting positions occupies but a few seconds. To facilitate the operation, the apparatus has been given the form shown in Figs. 41, 42 and 43. The pointers are heavy steel bars graduated every ten yards up to 10,000 yards and supported at their outer ends on light brass rollers. The spring pencil fits in a slider that moves along one of the pointers. When the slider is pushed along its pointer until its edge rests against the other pointer, the middle of the spring pencil is exactly at the point of intersection of two lines drawn from the centers of the pivots of the pointers; so that to mark the position on the chart of the enemy upon whom the telescopes are directed it is merely necessary to push down the spring pencil with the finger. The distance of the position from this instrument can be read at once from the graduated pointer through an opening in the slider, and the direction can be read at once from the graduated disks shown on the right of Fig. 43.

As installed at Fort Hamilton, the base line is 985 yards. In "tracking" moving vessels and in plotting the positions of known objects situated in different parts of the lower bay, some as distant as 9,000 yards, no error as great as 1 per cent. was discovered on the official or the preliminary trials.

THE BALTIMORE ELECTRIC SUBWAY SYSTEM.

THE increasing number of overhead electric pole lines in the city of Baltimore, Md., carrying not only telegraph and telephone, but electric light wires at high tensions, made it long ago apparent that some system of burying the wires in the streets was desirable. It was not, however, until June, 1895, that any decisive action was taken, when the city council passed an ordinance creating an electrical commission to inquire into the question and to submit a plan for the construction of a system of conduits for the accommodation of all the overhead lines within the city, except the trolley lines.

This commission has just handed in its voluminous and exhaustive report which consists substantially of the report of its engineer, Mr. Nicholas S. Hill, Jr., whose plans the commission recommends for adoption by the city council.

Mr. Hill in his report first points out the necessity for the creation of a department or bureau which shall have full charge of all electrical construction in Baltimore, with power to formulate rules for installing wires, to inspect all wiring work, etc.

As regards municipal control, Mr. Hill is unreservedly in favor of the municipality building and controlling the subways absolutely, the people at the last election having authorized the expenditure of $1,000,000 for an electrical subway system.

The map, Fig. 1, indicates the area within which the wires are recommended for placing underground; beyond these limits pole lines are to be used, erected and maintained under certain specifications and rules.

The method of subway construction recommended is that of the "drawing in" system, consisting of ducts or tubes for trunk lines. Mr. Hill describes and discusses four types of conduit for this purpose, namely: 1. Cement lined pipe of the National Conduit Manufacturing Company. 2. Wrought iron pipe. 3. Camp terra cotta conduit. 4. McRoy terra cotta conduit.

As regards the cost of the trunk line construction, the curves, Fig. 2, show the cost per foot per duct of the four types of conduits mentioned above, when laid under Belgian blocks; the report also gives similar curves for cobble and asphalt pavements. In Mr. Hill's opinion the cost of wrought iron pipe construction would be prohibitive, and while stating that each of the remaining types will give good results recommends the adoption of either the Camp or the McRoy terra cotta conduits for trunk lines.

FIG. 3.—METHOD OF TRUNK LINE, LATERAL AND BRANCH CONSTRUCTION AND HOUSE CONNECTION, BALTIMORE ELECTRIC SUBWAY.

It having been proposed to run the telegraph and telephone wires in ducts separate from those carrying high tension currents, a plan has been elaborated with that end in view, although Mr. Hill's personal observation leads him to the belief that there is no real reason why all classes of service should not be placed in the same conduits. In substantiation of his position he refers to the report of the Electrical Commission of Washington, D. C., and letters received from various sources by that commission. For the combined system of conduits there is recommended a combination of two and three-inch ducts. If the separate system of ducts is decided upon, all 3-inch ducts are recommended for telegraph, telephone and other low potential circuits, and the combination of two and three-inch ducts for the electric light and other high potential circuits.

Plan showing Distribution, over
Trunk Line - Wrot Iron Pipe.
approved. Nicholas Hill, Jr. ...... Engineer

FIG. 4.—PLAN OF DISTRIBUTION OVER TRUNK LINES, BALTIMORE ELECTRIC SUBWAY.

The house service distribution recommended for the two classes of wires is illustrated in Fig. 3. For telegraph and telephone distribution, it is as follows: Through wrought iron, cement lined tubes, or terra cotta pipe, to pole terminals situate in each block, and from thence overhead to each subscriber. For electric light and other high potential distribution, through wrought iron pipe and house service boxes to consumer, as shown in Figs. 3 and 4.

After discussing various methods of ventilating conduits, Mr. Hill recommends the delivery of fresh air to the manholes by compressed air or blowers operated from a central station, notwithstanding the initial cost which such an installation and its maintenance entails.

The rentals for ducts in the Baltimore conduits are calculated to vary for a separate system, from 15 cents per foot for wrought iron tube construction, to 9¼ cents for the McRoy tile construction, both being 3-inch ducts; the cement lined tube figures at 12¼ cents. For two-inch ducts the rental is calculated at 7 cents for the McCoy and 6¾ cents for the Camp tile.

The rentals to be charged are intended to pay the interest on the amount of stock issued, to refund the sinking fund, so as to redeem the stock at maturity, and to cover the cost of depreciation, superintendence and maintenance. It is proposed to build the subways at least 50 per cent. larger in capacity than the present service requires.

The report contains a number of valuable tables and other statistics relating to underground and overhead wire construction, and altogether is one of the best documents of its kind which has come under our notice.

COMMERCIAL CABLE COMPANY MORTGAGE.

A mortgage has been filed with Register Sohmer for $20,000,000, given to the Farmers' Loan and Trust Company by the Commercial Cable Company, pledging all its telegraph properties, rights, privileges, and franchises, including those of the Postal Telegraph Company. The mortgage is given to secure an issue of 500 4 per cent. gold bonds and debenture stocks, which aggregates the sum of the mortgage.

HARTFORD, CONN.—A joint special committee of the Hartford City Council has reported against the necessity of a municipal plant. The cost would be $400,000, and there would be no saving over the rates of the Hartford Electric Light Co., which for a ten year contract would make even better terms with the city.

VOL. XXIII. NEW YORK, JANUARY 13, 1897. No. 454.

MAKING OR BUYING ELECTRIC CURRENT.

OUR columns have recently contained various articles on the relative economy of current generated in so-called block stations, and that distributed from central stations. Thus far it may be fairly considered that the central station has come off best, and that its predicted "doom" need not scare electric light stockholders into sale of their holdings. It seems that our friends across the sea have had a somewhat similar question put before them, but rather more in the form of a comparison between the cost of isolated plant and central station lighting. Our contemporary, the London "Electrical Review," in a recent number publishes a number of letters from engineers in reply to the query: At what point does it become cheaper to make one's own supply of the current than to buy it? As might have been expected, the majority of opinions amount to saying that it all depends, and that to answer the question intelligently one would have to go into details of every case. One writer appears to take 400 16-candle-power lamps as the point where an isolated plant can be profitably operated, while another puts it at 400 8-candle-power lamps. Neither of these estimates can, of course, be taken as a criterion for the United States, owing to the disparity in the cost of gas for driving the gas engines, or lighting direct. One correspondent of our contemporary touches upon a question which has already on numerous occasions cropped up in experience on this side and that is, the connecting of the isolated plant circuits to the central station mains when the load becomes so light that it no longer pays to run the isolated generating plant. The English engineer doubts whether a central station has the power to refuse the demand for occasional current; from which it would appear that the question has not been brought to an issue there, as it has with us. We believe that enough judicial decisions have established the obligation of the central station to supply current to all who apply for it along the line of the conductors. Even if such were not the case, we believe it is good policy to give connection to all isolated plants. As a rule, current would only be called for during hours of light load at the station and would therefore help to maintain the load curve. But on the other hand the fact of a street connection being available always acts as an incentive to make use of it. Of course, the rates to be charged for current would have to be graded in proportion to the quantity called for, and when this is done we can see no hardship in the arrangement. Besides, an isolated plant with a street connection may make the owner more open to argument as to the greater economy of the central station current than a plant not so connected. This whole question of the central station versus the isolated or block plant is slowly but surely working itself out towards a natural solution. As a matter of fact, humiliating as the confession may be, we have but just begun to generate and distribute current on anything like an economical basis, and there is still plenty of margin for improvement in sight. From what we know and what can reasonably be hoped for, we do not hesitate to say that in large units the electric incandescent light will be furnished cheaper than gas light at no very distant day, under all ordinary conditions of service.

THE LATEST "YOUNG GIANT" IN THE ARTS.

ELECTRICAL engineers have so long and so patiently endured the reference to the "infancy of electricity" by popular writers and speakers, that they have become thoroughly reconciled to their misery. But we are glad to believe that the title to infancy is now to be transferred to another type of motive power, to which it will be applicable with even less propriety than it was to electricity. An indication of this transfer of juvenile honors is observable in an article by Mr. C. W. Shields in the "Engineering Magazine," entitled "The Rise of the Young Giant, Compressed Air." Considering that compressed air was practically applied as a motive power, years and years before electric motive power was thought of, the infant seems to have remained somewhat stunted. However, a glance at Mr. Shield's interesting article shows that compressed air is being employed in a variety of ways, among which may be mentioned the driving of rock drills, the cleaning of car cushions, for pneumatic track sanders, for operating sand paper machines, pneumatic ditching and grading machines and for compressed air locomotives, together with a variety of other works, such as caisson-sinking. One cannot deny that the record here presented is a most interesting and encouraging one, and that a good future lies ahead for compressed air, but we fail to see that this expansion can lie in any other direction than in special applications, while as a motive power, pure and simple, its sphere is sharply circumscribed by the new comer, electricity. Take the case of the compressed air street car. From what one reads and hears on the subject nowadays, one might be led to believe that here was an entirely new departure, something that had never been thought of, let alone tried, before. Yet nothing could be farther from the truth. As a matter of fact compressed air cars have been in actual operation for years past in Europe and we take it that this very fact, made so much of by the advocates of compressed air, constitutes the best argument against them. Surely these European roads have been running long enough to make their cost of operation a known factor, yet in spite of this the extension of electric railroading in Europe bids fair to match our own activity in this field. What does this indicate? Simply that neither in cost of operation nor in ease of handling, can the compressed air car be ranked with the electric. We need not here refer to the danger of transporting vessels on each car carrying 2,000 pounds pressure to the square inch, though an unpleasant experience due to this fact made itself manifest on one of the cars now in operation in New York quite recently. Nor can we assume that it was fashion or a fad that dictated the adoption of electricity with such spontaneity. After weighing all the evidence one is forced to the conclusion that the merits of electricity, pure and simple, have made it in many respects the motive power par excellence, not only for railway but for all other work where power is applied, either directly or transmitted. If our compressed air friends are open to argument we would advise them to concentrate their energies on special applications of which some have already been developed and the field for which is practically a virgin one as yet.

WIRE *vs.* SHAFT.

THE pithy and epigrammatic article with which Dr. S. S. Wheeler favored us last week on the passing of the pulley went right to the heart of a great matter. One does not realize how great are the advances being made in power transmission until one studies Dr. Wheeler's own work and views, or connotes, such data as that furnished us this week in Mr. John McGhie's striking communication. It is evident that whereas a mill or mine owner once looked upon electric power as a kind of last resort to be tried only if the work was abnormally difficult, electricity has now to be taken into consideration first and foremost. The report that coal operators in the Hocking Valley are proposing a wholesale adoption of electric power because strikes have been crippling their productive capacity, and because they can get light, power, traction and ventilation all from one source, is simply another indication of the way the industrial wind is blowing.

Returning to Dr. Wheeler's points in favor of direct driven apparatus, where the power is put directly in the tool or machine, we may say that his terse arguments find remarkable proof in the figures of the recent tests submitted to the American Society of Mechanical Engineers by Prof. C. H. Benjamin, of the Case School of Applied Science, Cleveland, O. He made these tests of shafting in 16 different establishments, comprising rolling mills and stamping mills, bridge works, general machine works and screw shops. In each establishment indicator cards were taken every hour during the day, and their average was taken as showing the total amount of power needed to run the mill or shop. During the noon hour or at night cards were taken from the same engine while it was driving the shafting only, and the average of these cards was taken to represent the power necessary to overcome the friction of the shafting. The percentage of power necessary to run the shafting was the smallest in the case of a shop making steel wood screws, where it was 14.5 per cent. There were 14 men employed here and 117 horse-power was required to run the works. The greatest ratio, 80.7 per cent., was in a bridge shop employing 80 men, and where there was an unusually large amount of shafting for the number of machines used, only 59.2 horse-power, all told, being employed. In a heavy machine shop employing 225 men and requiring 168 horse-power, 54.2 per cent. was used on the shafting, and in another plant about the same size and character, 57 per cent. was needed. Prof. Benjamin's investigations may be summarized by stating that in the sixteen establishments visited there were 15,897 feet of shafting, 1,808 horse-power was employed in running the entire series of works, and 979 horse-power, or 51 per cent. of the whole, was spent in driving the shafts, main belts and counter shafts. These figures are startling and show how wasteful some of the methods must be even in places where ordinary care and average mechanical knowledge are certainly not lacking. Admitting that in the electric system, there are offsetting losses in the conversions of the power, the line resistance, the rheostats, etc., it is obvious that the new method has advantages. Indeed it is hard to believe that today any new mill or factory will equip without having investigated the use of electricity, or that, with rare exceptions, it will not be found best to put in a combination lighting and power plant, with the alternative or adjunct of connection to the lighting mains of the locality.

BETTER ELECTRICAL PROSPECTS.

THERE can be no question as to the fact that there is a general improvement in electrical trade. Wherever one looks throughout the country, new work is in hand, or about to begin, on lighting plants, electric roads, telegraph offices, telephone exchanges, power equipments, and the various other branches of the industry. In the bulk and aggregate, this work far exceeds that of any recent year, and has already stimulated production. At the same time, while prices remain low, and will probably never attain old levels again, better rates are being secured, and a closer agreement among the manufacturers tends to keep them up. There is not a great deal of débris now lying around to tempt the consumer because it is cheap, and to harass and check the efforts of those introducing new and improved apparatus.

The stock market is still limp and apathetic, not knowing exactly what is the matter with itself, "letting, I dare not wait upon I would." In electrical securities, not a great deal was done last week. G. E. was sold to the tune of 18,581 shares at from 34⅝ down to 32¾, closing at 33½. Of W. U., 6,958 shares were sold, down to 82¾ and closing at 84⅛. Erie Telephone and Telegraph sold at 64½, American Cable at 90¼, Edison New York Electric Illuminating Company at 103¾. The bond market was slow and dull, and sales so small as not to be worth mentioning—little lots of 10 and 20. On the Boston market, American Bell Telephone reached 210. In Philadelphia, Electric Storage Company reached 28⅜.

ELECTRIC TRACTION IN EUROPE.

MR. E. H. JOHNSON has recently returned from Europe, and having spent some six months in wide travel, his shrewd observations are, as usual, full of interest and importance. It is well understood also that he has done some good work for the introduction of new American electrical apparatus, thus supplementing the pioneer work of earlier years with other important innovations and novelties. His comments on the electric railway situation are very interesting, and tend to confirm the current idea that England is going into an electric railway regime, largely on American lines. But with some noteworthy differences. Mr. Johnson expects to see the trolley limited to the outer circles of large cities. In the denser areas, he looks for a large adoption of the conduit system, not of the open type, but particularly of the closed conduit sectional type, in which field his efforts are well known to have been concentrated for some time past. In England, for example, conduits must be shallow, pipes must not be diverted or disturbed as here, and the public knows that the day of the cable conduit has gone by. Therefore, in turning to electricity, it would prefer a closed conduit as being the shallowest of all in its disturbance of the street, and as not being an open sewer. As to automobile cars of the air and gas types, Mr. Johnson finds them "exploded" in more senses than one. Both the open electric conduit and the storage battery cars are also, to his way of thinking, falling rapidly out of favor in Europe. This summing up of the situation at a moment of new departure by a close and highly competent observer is unusually worthy of note.

PATENT PROTECTION.

SOME of our American patent companies carry their patents on the property account for a good many million dollars. The Allgemeine Electricitaets Gesellschaft, of Germany, which probably stands second to none in respect of variety of work, holds its patents to be worth one mark. When one figures how much these patents cost to defend, making them a source of outgo rather than of income, the lower valuation seems reasonable. The Tesla phase patents have just been revoked in Germany, as we announced last week, on some technical ground. They are of great, undoubted value, but thus figure as a cost and loss. Speaking of rotary engines, the "American Machinist" says that 1,370 patents on them have been taken out in this country, and that most engineers would value the lot at about 10 cents. Granting, as we all must, the desirability of patent protection, it would seem that the protection lies less in the patent than in the intrinsic merit of the apparatus made under it.

OUR NEW YEAR NUMBER.

IT is literally impossible to reply individually to all the congratulations upon our New Year Number—its size, style, contents and other features. We are glad to have done so well. We feel we could have done much better, and that if we did not, the fault is all our own. A few contributions were belated. Up to the present time, advertisements have not ceased to come in, and but for our determination to have the paper out in its regular week of issue, it might perhaps have been 264 pages instead of 132. Our regular day of publication is Wednesday, and this issue was distributed Friday. A snowball once it gets rolling has the property of rapid growth, and our New Year snowball got rolling at such a pace, it soon flattened out all our ordinary facilities, and threatened to become a devastating avalanche. However, we survive for further effort, and it looks as though we still had our friends with us. It is not an easy task to print over 15,000 copies of a paper of 132 pages, but we trust all our obligations to readers and advertisers have been discharged by this time and that we are in line for duties and favors to come.

THE South has been a storm center of "independent telephone" fighting and some of the newcomers have stirred things up considerably. But the old occupants of the territory are in nowise dismayed. In fact, they report large accretions of business, and have gone in for new exchanges. The latest is that going up in Savannah and illustrated in this issue of the Engineer. It will embody all that is latest, costliest and best in modern telephonic work.

THE shutting down of central stations by accident or fire becomes rarer and rarer, and the recent destruction of the plant of the Newark, N. J., Electric Light and Power Company is therefore a mysterious affair, as there seems to be nothing but incendiarism to explain it. We are glad to note that large rewards have been offered, but what pleases us most is the celerity which President P. N. Jackson displayed in renewing the plant. We made note last week of the rushing through of some apparatus from Cleveland, and like dispatch was shown in regard to machinery from Pittsfield, Mass. Moreover, all available plants in the vicinity were looped in or switched on, and for some days past the station has been running as though the disaster had never happened. If such interruptions must come, it is encouraging to see them met with so much promptness and energy.

DR. D'ASONVAL writes to the New York "World" that he is a "great admirer of the bold work of the American electricians," and that he wants them to attack as their next problem for solution the cure of tuberculosis. He believes it to be well within possibility, and says truly that it is far more worthy of the effort of great philanthropists than electrocution. All will agree with him. Electrocution is a base method of employing a noble agent. To cure tuberculosis might well occupy the lifetime of the greatest electrical discoverer. There have been hints of a near approach to the goal named.

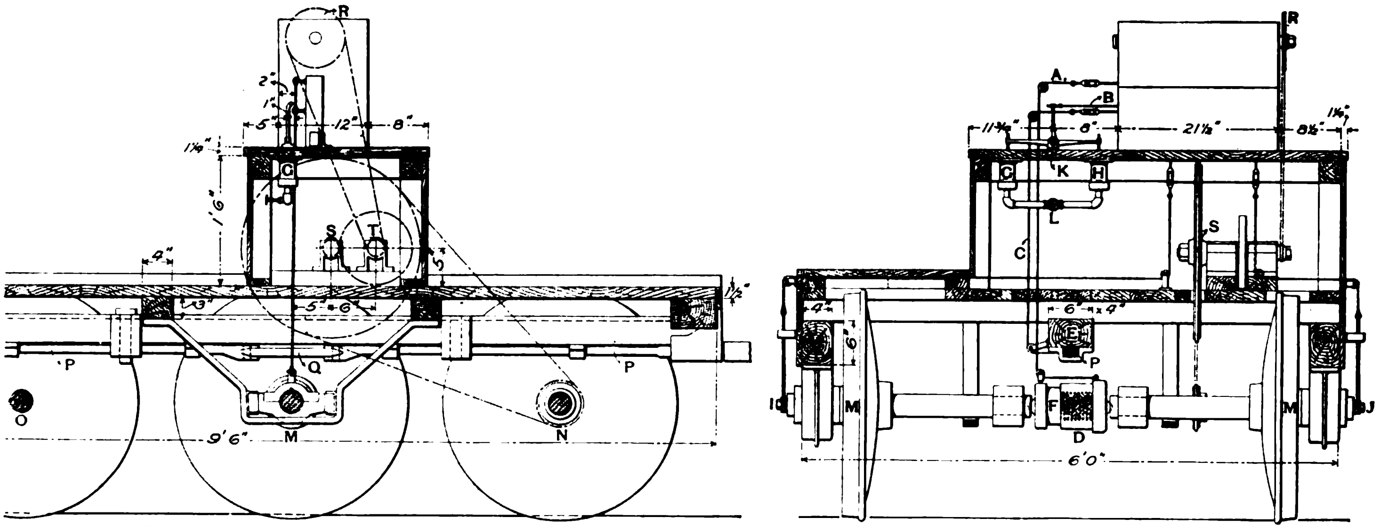
A well informed mechanical engineer of high standing, remarked in conversation the other day, that the sharp competition in the late hard times had in many instances lowered the quality of the raw material so that analysis had been more than ever necessary, and if not resorted to rigorously had led to many subsequent failures of apparatus. Perhaps this is true to some extent in some electrical lines. Mere cheapness does not promote high quality, and it is to be hoped that all lines may now move back quickly to the point at which a decent profit can be made without the straining of recent years.

ELECTRIC TRANSPORTATION

THE BOWEN DYNAGRAPH CAR.

IN his paper on "Track and Track Joints"[1], read at the meeting of the American Street Railway Association last October Mr. M. K. Bowen, superintendent of the Chicago City Railroad, described a dynagraph car whose indications show graphically the condition of the track and which gives an accurate index of the amount of money which can profitably be spent upon it.

The car weighs 3,865 lbs., and when the records are being made it is fastened to any ordinary car which is drawn over the track at a uniform speed. It has a platform 8 ft.x 10 ft., mounted on a single truck. The dynagraph automatically records the conditions of the track, and Mr. Bowen's original idea was to make the records show the excess of power which is required to draw the car, because of the faults, in dollars and cents per ton of load when capitalized. This result multiplied by the ton miles on any road tested would show accurately the amount which should be expended on track reconstruction and put a stop to expensive guessing. In regard to the above plan, Mr. Bowen writes, as follows:



FIGS. 1 AND 2.—THE BOWEN DYNAGRAPH FOR STREET RAILROADS.—LONGITUDINAL AND TRANSVERSE SECTIONS.

"It was our original idea to rule off paper which would express in dollars and cents this dynamometer pull for a ton mile, but experience has demonstrated that it is unnecessary, as any intelligent man using the instrument for a short time is able to make a deduction from the dynamometer pull, express it in dollars and cents per ton mile, which multiplied by the ton miles on that particular road for one year will give you, capitalized, the amount that you could, with judgment, spend upon the repairs to tracks."

"Anyone using the car for a short time, making a few calculations from the profiles, reducing the excess horse-power for poor joints, etc., from the dynamometer pull to the cost in dollars and cents for this excess pull, will be enabled in a short time to tell by simply looking at the dynamometer pull the cost per ton-mile of excess horse-power expressed in dollars and cents.

The records show high and low rails, low joints, gauge, drawbar pull and variations of track level. The records are plotted on a paper 18 inches wide, which unwinds from the drum R, Figs. 1 and 2, at the uniform speed of 1 foot for every 1,000 feet of track.

The dynamometer consists of two drawbars, P, Fig. 1, one at each end of the car and extending beneath the platform to a distance of about 1 foot, from each other. Between the two adjacent ends a spring is placed, and a movement of this spring changes the relative length of the wire C and moves the recording arm, which makes a trace on the drum R. The apparatus for showing the difference in level of the rails is mounted on the platform and consists of two cups of mercury, G and H, Fig. 2, into which dip two plungers connected to a recording arm by means of the wire B.

The records showing the high and low joints, or other variations in surface, and the changes in gauge are accomplished by means of the midway wheels M, which rise and fall as the surface of the track varies, and also move apart and approach each other as the alignment changes. The journals allow a free vertical and longitudinal movement of the midway axles. The car rests directly on the other axle bearings, N and O, Fig. 1, so that the vertical movements of the midway wheels give an accurate measure of the low places. As the forward wheel passes over a low joint it drops down into it, and this causes a relative rise in the midway wheels, which is recorded on the paper in one direction from the normal line; and then the rear wheel drops into the low joint, which is recorded in the same manner as when the front wheel passed the low joint. The passing of the three wheels over a low joint causes the glass pen to make two short deflections in one direction and a much longer deflection between the other two and in the opposite direction. Only the middle deflection is used in determining how low the joint is.

The manner in which the differences of the gauge is recorded by means of the longitudinal movement of the wheel on the midway axle will be seen by referring to Fig. 2. In the middle of the axle is a cylinder D, containing a spring which is compressed or extended as the gage increases or diminishes. Any change in the relative position of F and D will move the wire A which is attached to the recording arm, which marks the gauge.—The "Railroad Gazette."

THE NEW FORM OF ELECTRIC RAILWAY CONDUITS FOR NEW YORK.

AS already announced by us, the Metropolitan Railway Co. has decided to adopt electricity as its motive power on the Fourth, Sixth, Eighth and Madison avenue lines, and has already ordered 300 car equipments.

The details of the underground system have been practically all worked out and we present in the accompanying engraving a sectional view of the conduit which will be installed. As will be noted, the entire depth of the yoke is only 2 feet 6¾ inches so that but a very shallow excavation will be required in marked contrast to the depth demanded by the cable conduit. The yokes will be spaced 5 feet on centers, and the hand holes where the insulators are attached, at 15 feet.

The conducting rails have been the subject of much thought and as a result a special section has been adopted, as shown, being a modified T-section with the edges lapped over, as it were, so as to give additional stiffness, to resist the pressure of the plow contacts. The conducting rails are held in position by fork brackets, which are held firmly by the insulators of porcelain.

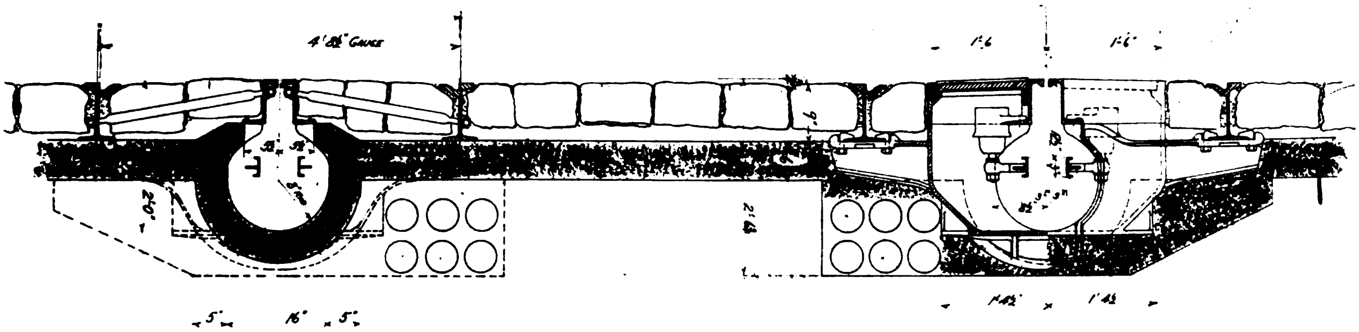
In place of the 7-inch rail heretofore employed on the New York cable roads, rails 9 inches high will be used, weighing 106 lbs. to the yard. These are held in position by tie-bars as usual. The 7-inch slot rail is retained. A bed of paving concrete 6 inches thick forms the sides of the conduits and connects the two.

---

[1] The Electrical Engineer, Oct. 28, 1896.

Our engraving shows a view of the double conduit, the left hand section being taken midway between the hand holes and the right hand at the hand hole.

Work on the underground construction will be begun as soon as the frost is out of the ground. Two electric power plants will be installed, one in the present cable power house at Twenty-fifth street and Lexington avenue, which will contain four 800-kilowatt generators. This station will supply current below Fifty-ninth street. The other station will be built close to the present electric power house now supplying current to the Lenox avenue electric road, at Lenox avenue and One Hundred and Forty-sixth street. This section will supply the lines above Fifty-ninth street. To provide for the feeders, ducts will be laid on the inner side of the conduit, as shown, and in these conductors ranging from 300,000 to 1,000,000 circular mils will be drawn.



Section of Conduit Adopted for the New Electric Roads of the Metropolitan Railway Co., New York.

THE LOVE CONDUIT RAILWAY SYSTEM.

BY M. D. LAW.

It is a well-known fact that electricians in general deny that underground trolleys can be successful, but after nearly four years of practical success with the Love conduit system, I can unhesitatingly say, that it has been an unqualified success, and that all the claims of the Love company can be fulfilled, namely:

First—That it can be kept in operation 365 days in the year.

Second—It is absolutely impossible for any one to be injured by the electric current.

Third—It requires no skilled labor to operate.

Fourth—Cost of maintenance as low as any known power.

Fifth—Does not increase the cost of insurance along the line of the road.

To fulfill the first of these claims, requires a first-class roadbed, and that the electrical equipment be of the very best, thoroughly protected from mechanical injury and easy to repair .

It has been kept constantly before me, that all roads are subject to breakdowns, so the idea has been to reduce these accidents to a minimum, and when they do occur, to be able to repair them without delay to the cars; this has been carried in the Love system to a state of perfection that is surprising.

The shape of the yoke is such that it protects the insulator from all moisture and allows of quick access, to admit of inspection or repairs. The slot rail is of such shape that it thoroughly protects the conductor from all sleet, mud or any conducting material reaching it from the slot. It also protects the conductor from any damage by the trolley from a derailment of the car, so that the line is at all times in a condition for operation. All insulators are so placed that they can be easily reached from the surface, quickly removed and a new one substituted.

The conductor is of copper, made up of short sections, each section having a peculiar expansion joint; this joint has a greater conductivity than the rest of the conductor, and the conditions are such that it is at all times bright, and free from corrosion. Should it become necessary to change any one of these sections, it can be done in four minutes.

The conductor is so arranged that should a ground occur, it can be traced to its exact location and removed in a few minutes, and from the fact that a metallic circuit is used, a ground on one side of the line will cause no trouble in the operation of the cars.

The conductor being supported within a few inches of the surface, with an underbearing trolley, gives successful running, even though the conduit may be full of snow. The trolley has been perfected to such a point that it is extremely simple, and will run 20,000 miles without repair, other than wheels and bushings, and I find that the regular trolley wheels will make more than double the miles of run that they will on the overhead wire.

The second claim is covered by the fact that the conductor is so placed under the protecting slot rail that it is impossible for it to be reached from the surface.

For the third claim, its construction and operation is so simple, that any ordinary trackman can be very soon instructed, how to locate and remove all trouble.

As regards the fourth claim, it is a well-known fact that a street railroad can be operated cheaper by electric than any other known power, and the Love system is nothing more than the overhead trolley, placed beneath the surface, with a metallic circuit. There is no appreciable loss of current in insulation, bad bonding, or loss between wheel and rail, from sand, mud or snow on the rail. There being no current in the rail there is no electrolysis on the surrounding gas or water pipes.

The cost of line maintenance is reduced to a minimum, and has been proved to be much lower than overhead construction.

It does not increase the insurance along the line of the road from the fact that there are no grounded circuits and that there are no wires above the surface of the street.

REPORT OF NEW YORK STATE RAILWAY COMMISSION.

Among other things, the New York State Railway Commission speak in their last report of the dangerous overcrowding of street cars, especially on Sundays and on holiday occasions. Such overcrowding, the report says, can only be prevented by a rigid legislative enactment providing a severe penalty for permitting a greater number of passengers to ride than can be conveniently seated and stand in the aisles. The Commissioners say of the evil of jumping on and off moving trolley or cable cars: "The evil which this recommendation seeks to correct is particularly noticeable in New York City, where dexterous efforts on the part of passengers—the result, no doubt, of constant training in the athletic but dangerous exercise of getting on and off moving cars—alone prevent a large increase in the number of accidents. There is no reason why as courteous treatment should not be accorded the public by street surface railroad employés as is exacted upon the steam surface lines, or why careless and dangerous methods of operation, which would be regarded with horror if practiced upon the latter, should be tolerated upon the former."

The recommendation that a law be passed requiring all street surface cars to be heated is renewed. There is no longer any excuse for electric cars not being heated.

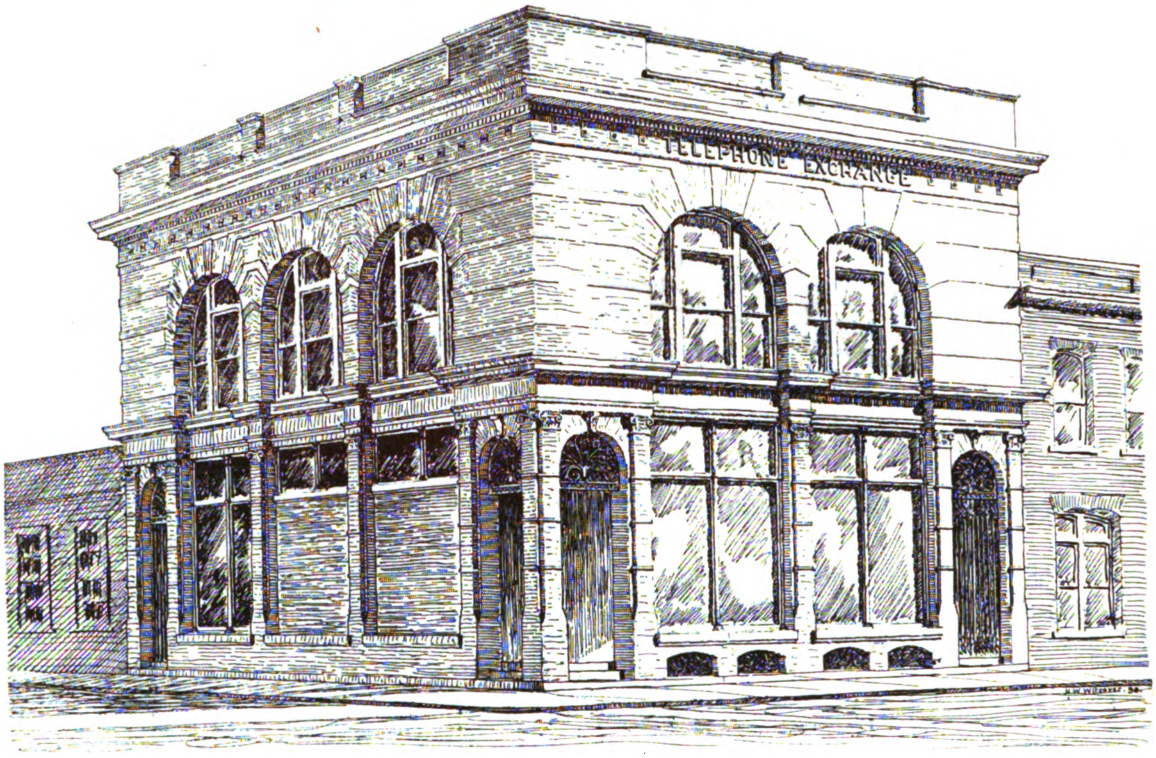
FOUR-CENT FARES IN MILWAUKEE.

A Milwaukee special says: "William Nelson Cromwell, who has been here this week on account of the 4-cent fare litigation, caused a good deal of surprise by his statement that Milwaukee Electric had not been earning running expenses during the past eleven months. Mr. Cromwell assured the court that the New York investors had provided Milwaukee with the finest trolley system in America, and that they had never received a cent in dividends. He added that to enforce the four-cent fare ordinance would mean bankruptcy. The company lost a good deal of money by reason of the strike of last summer, but the general impression has been that it was earning expenses, an impression which was strengthened when Milwaukee Electric recently bought out the power and lighting business of Pabst, the brewer. It is believed that the connection formed with the new interurban line, which is ultimately to extend to Chicago, will be a good thing for Milwaukee Electric, especially in summer. The line is now in regular operation between Milwaukee and Racine."

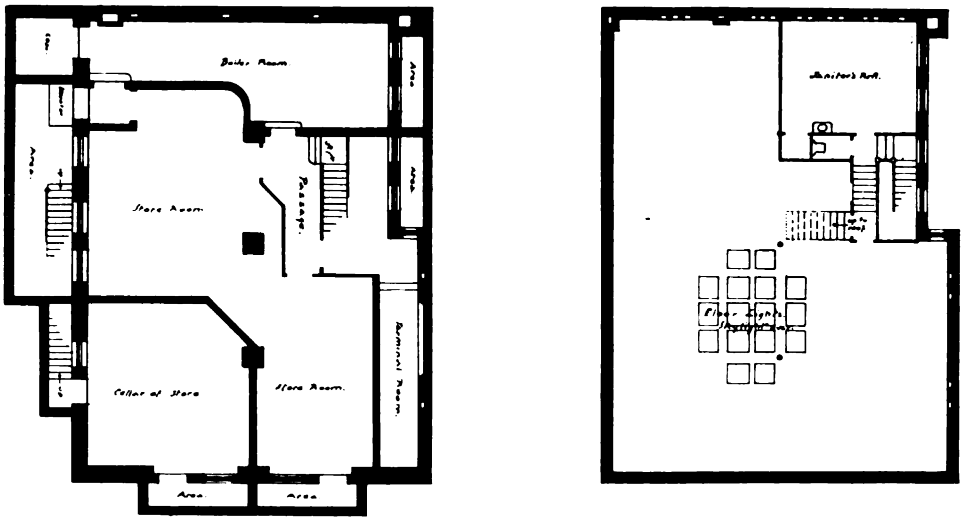
TELEPHONY AND TELEGRAPHY

NEW SOUTHERN BELL TELEPHONE EXCHANGE AT SAVANNAH, GA.

THE South has for some time past been the scene of considerable activity in the telephone field. The work there implies many conditions of difficulty and involves many problems not dealt with elsewhere; offset by the general advantage that the mildness of the climate favors the steady maintenance of regular service. The distances are very great, the centers of population are not large, the easy-going nature of many of the people does not encourage swift communication, and the public is not inclined to pay the high rates which make luxurious refinements in the system possible. Under these conditions, however, the Southern Bell Telephone Company has been persistently developing its exchanges on a modern basis of technical perfection while the growth of the long distance lines in the great Southern States has been remarkable. In those cities where commerce and trade are active, the company has not been slow to enlarge its facilities, and it has now several new and extensive exchanges on its list, comparing favorably with those anywhere else in the country. One of the latest to be designed is that for the bustling, progressive city of Savannah, Ga., which with a population of over 60,000 does a business worthy an even larger community. The building design was made by Mr. A. S. Eichberg, a well-known Southern architect, and consists, as will be noted, of two main floors, with a basement floor and an attic floor. The building is constructed of the handsome, bright tinted "telephone



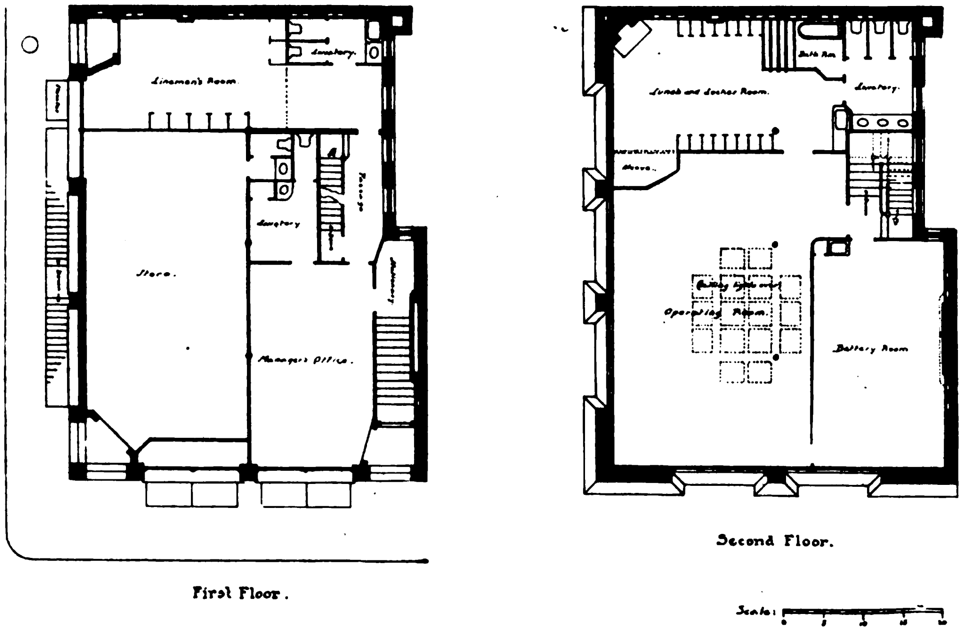
THE NEW SAVANNAH, GA., TELEPHONE EXCHANGE OF THE SOUTHERN BELL TELEPHONE AND TELEGRAPH COMPANY.
(*A. S. Eichberg, Architect.*)



Basement. Attic.

THE NEW SAVANNAH TELEPHONE EXCHANGE BUILDING.

brick," made by the Perth Amboy Terra Cotta Company, a material that has given quite a distinctive and characteristic aspect to several of the finest telephone exchanges in the country and whose beauty no amount of general use and no lapse of time appears to mar in any way. The outside dimensions of the building are 45 feet by 60 feet. On the ground floor a large store has been laid out, which in the long run the company will doubtless need for its own operations. Under it is the basement which extends also under part of the sidewalk. Above it is the main telephone floor devoted to the general uses of the exchange. The operating and battery department, with the area for the cross connection board, occupies a roomy space 40 feet square; and on the same floor are the lunch and dressing rooms, 16 feet by 40.

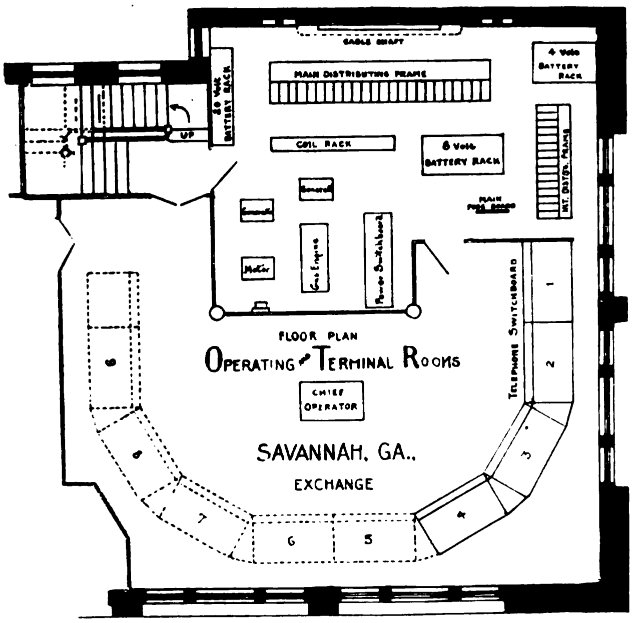


First Floor.

Second Floor.

The New Savannah Telephone Exchange Building.

The plans shown herewith indicate the location of the various rooms. The manager's office is 16 feet by 40 and the linemen's room 14 feet by 40, so that there is not the least cramping in any respect. The cable duct will be noted at the side of the building, a space 8 feet long and 1 foot wide. It connects in the basement with the underground system laid for the company by the National Conduit Manufacturing Company using their cement lined pipes.



Operating and Terminal Rooms, Savannah Telephone Exchange.

The switchboard now being built by the Western Electric Company, will provide for no fewer than 2,000 subscribers, thus taking care of the natural expansion of the company's patronage for some time to come. It will be on the metallic system plan, and will be operated on the now familiar method of visual indication by means of incandescent lamps. It includes all the latest devices of the Western Electric Co. for facilitating the dispatch of business so necessary in a city like Savannah and at periods like the busy cotton shipping season. The arrangements for the operators also comprise everything that could be thought of to increase their comfort; and the whole building, far South as it is, is heated by steam.

The exchange will be self contained as to its generative capacity, current being furnished by means of the equipment shown in the plan of the operating room, a gas engine furnishing power, with electric motor as an adjunct or auxiliary, no chance of breakdown being taken.

Mr. R. H. Polk, the manager of the exchange is an active and successful young telephone man, who began his career very early, and who since his work in Richmond nearly 20 years ago has invented and devised many telephone improvements. He not only has the interests of the exchange to look after, but finds much to occupy his attention in the rapidly extending long distance service which now gives Savannah direct connection with Atlanta and with the whole North.

THE TELEPHONE IN OUR HOMES.

BY W. H. ECKERT.

The editorial entitled "The Telephone in Our Homes," which appears in The Electrical Engineer of Dec. 30, recalls to mind that that which is now cited as a novelty, namely, the transmission of music over the wires to subscribers, was accomplished years ago by the Bell Telephone Companies.

The City & Suburban Telegraph Association (Bell Telephone Exchange), of Cincinnati, O., of which the writer was general manager, placed Blake transmitters in all the principal theatres and concert halls of that city in 1879. Subscribers had music "on tap" at all matinee performances and every evening, and frequently as many as four hundred subscribers were connected on to the music lines. Many of the subscribers, desiring to entertain their friends, applied to the company for additional receivers and often twenty-five or thirty receivers were furnished so that the subscriber and his friends could enjoy the performances.

I call to mind the stand taken by the manager of the Grand Opera House. A subscriber to the telephone system told the manager that he did not intend to go to the theatre because he could sit at his home, hear the orchestra, the songs and even the steps taken by the performers when dancing. A few cases of this kind and the manager ordered the transmitters removed from the theatre. The same may be said to have applied to the concert halls. Then, besides, the American people use the telephone as a business device and the giving of music interfered with the service considerably. It also lost its novelty, and, except in isolated cases, it has been abandoned.

In June, 1880, at the convention of the National Democratic Party, held at Cincinnati, the writer arranged with the chairman for two Blake transmitters to be placed on either side of his desk. Before the convention, score cards, showing the vote of each State, etc., were sent to every subscriber. Each subscriber was given connection, if desired, with the instruments at the convention hall, and during the three days of the session, more than one-half of the subscribers to the system were connected with those wires. People in all parts of the city heard the speeches of the chairman, roll-call and other matters relating to the business of the convention. It may be said that the affair was highly successful, and this, it will be seen, occurred over sixteen years ago.

The transmission of music, speeches, sermons, etc., has been accomplished by the licensees of the American Bell Telephone Company many times since, both for short and long distances.

At Cincinnati, the fire department and police headquarters were operated in connection with the general telephone system, each department having an exchange of its own. The operators kept records of all news items relating to each department for the benefit of the newspapers of the city. Then, besides, each subscriber to the general system could apply to either of the departments for any information relating to fires, arrests, disturbances, etc., at any time during the day or night. Fire alarms were sent in by telephone; officers were sent for in like manner.

The above, in a small way, accomplished nearly the same results as those secured at Buda Pest—it was simply a reversal of the plan followed at that place; instead of having the news sent to the subscriber, the subscriber applied for it. While the telephone may not be exploited to its greatest extent, I do not think that anything has been done in Europe that has not been done here.

THE TELEPHONE BUSINESS IN SYRACUSE, N. Y.

There has been a large increase in the use of the telephone in Syracuse during the last year, the average number of calls having increased from 15,022 to 16,022 a day. At the Syracuse exchange of the Central New York Telephone and Telegraph Company there are employed at the present time fifty-seven persons. Thirty-two of these are day operators, one is a night operator and one is the bookkeeper. The other employés are linemen and messengers. The company has, including wire in cables, 1,741 miles of exchange wire, of which 1,580 miles is strung on 50 miles of poles and 161 miles on buildings. There are 38 aerial cables 28,015 feet in length and made up of 2,045,740 feet of single wire. There are in use 1,621 telephones, of which 1,189 are in business places. During the year the number of telephones in use has been increased by 109. Following is a summary of the business of the year:

Local calls	5,848,000
Daily average of local calls	16.022
Toll messages sent	22,600
Toll messages received	32,000

ENGLAND'S NEW PACIFIC CABLE.

A dispatch from London of Jan. 5, says: It is stated here today that the Pacific Cable Conference has about completed its labors, nothing now remaining to be done except to sign its report, which will be done at a meeting of the conference that will be held a fortnight hence.

It is stated on good authority that the report will show practical unanimity among the delegates in recommending the construction of a cable, the testimony adduced having shown that the scheme is entirely feasible, and that, commercially and politically considered, it is necessary to Great Britain, Australasia and Canada. Some difference of opinion existed as to the relative share of the expense of construction to be borne by the mother country and the colonies, but the matter was adjusted by the delegates agreeing to recommend that, instead of carrying out the original proposition regarding the expense, Great Britain should pay a less sum than was first allotted as her share, the colonies making up the difference.

Drafts of the report, signed by the Canadian and Australian delegates, will soon be sent to their respective governments for their approval.

NEW YORK AND NEW JERSEY TELEPHONE COMPANY has declared its regular dividend of 1½ per cent. and 1 per cent. extra payable Jan. 15.

SOCIETY & CLUB NOTES

ELECTRICAL SOUND MONEY CLUB.

At a special meeting of the officers and committee of the Electrical Sound Money Club, held at the offices of the treasurer, Capt. W. L. Candee, 253 Broadway, New York City, on Friday, Jan. 8, it was voted that in view of the fact that the objects for which the club was formed had been successfully accomplished, the club be dissolved. It was also voted that the treasurer be appointed a committee of one to dispose of to some charitable object the small balance of cash on hand. Those present at the meeting were: Dr. S. S. Wheeler, of the Crocker-Wheeler Electric Company, chairman; Capt. W. L. Candee, of the Okonite Company, treasurer; vice-presidents, J. E. Ham, of W. R. Brixey, and Charles Blizard, of the Electric Storage Battery Company; General C. H. Barney, of the New York Telephone Company, chief marshal; A. C. Shaw, of The Electrical Engineer, and Stephen L. Coles, of the "Electrical Review," secretary.

Resolutions of thanks were passed for favors extended by various corporations and a special vote of thanks was tendered to General Barney for the excellent work he did in organizing and commanding the 1,832 men turned out in the business men's parade by the Electrical Sound Money Club.

NEW YORK ELECTRICAL SOCIETY.

The next meeting of the society will be held at Columbia College, on Thursday, Jan. 4, at 8 P. M. Mr. E. Leavenworth Elliott will give a paper on "Light, Its Distribution and Diffusion as Related to Quality and Efficiency." Mr. Elliott's paper is directed to the discussion of the means for making the light-giving element most effective. It will be illustrated with diagrams and apparatus bearing directly on the question.

LETTERS TO THE EDITOR

ENGLISH CAPTIOUS CRITICISM.

The following admirable letter from Prof. John Trowbridge appears in the London "Electrician" for December 25:

Sir: There is a tendency among critics to condemn a book for not comprising what it was not intended to contain. Such critics have a preconceived notion of what a writer should have included in his treatise; they glance through the pages in a superficial manner for what they think should be there, and not finding such topics expressed to their mind immediately condemn the treatise.

This pernicious habit of critics is well illustrated by recent criticisms[1] of Prof. Bedell's book[2] on the theory of the transformer. A writer in "Nature" sees nothing good in the treatise because it does not enter fully upon the practical details of transformers with iron cores. To do this Prof. Bedell would have been compelled to greatly increase the size and scope of his book. It was plainly his object to outline, so to speak, the scaffolding of the edifice, and to give in a clear manner the fundamental equations upon which the discussions of transformers rest, and to illustrate the use of graphical methods in such discussions.

Before the appearance of Prof. Bedell's treatise the student was compelled to rely upon books which were illogical collections of articles originally published in electrical journals and hastily thrown together in a book form. A just critic should recognize the endeavor of Prof. Bedell to bring order out of chaos in presenting the fundamental equations used in discussions of alternating currents in such a clear and instructive manner.

JOHN TROWBRIDGE.

Harvard University, Cambridge, Mass.

(We regret to note the increasing tendency of captious criticisms of American books by English reviewers, and the magnification of small faults to undue proportions. We will not undertake to seek a cause for this manifestation, but merely ask for American authors, whether of books or of articles, fair play with strict justice.—Eds. E. E.)

---

[2] "The Principles of the Transformer," by Frederick Bedell, 1896.

THE CHICAGO SCHOOL OF ELECTRICITY.

WE notice in your issue of December 30, a letter from Professor Frederick A. C. Perrine, in which he claims that we are using his name in our advertisements, and that such use is not authorized by him. He states, "I have no connection with the Chicago School of Electricity." Will you kindly state in your valuable journal that we have not used and are not using his name in our advertisements, and that we do not purpose to advertise, as Dr. Perrine has no connection with the Chicago School of Electricity whatsoever.

The Lesson Leaves, which were prepared for the National School of Electricity, have come into our control by purchase, and we have published them in book form, giving in the descriptive circular the names of the authors, and stating "published by the Chicago School of Electricity." Dr. Perrine admits in his letter to you that he did assist in preparing the lessons—the only thing we have stated in our advertisements.

No one who was financially interested in the "National School of Electricity" is in any way connected with the Chicago School of Electricity.

There can be no question of bad faith upon the part of the officials of the National School of Electricity, as we, knowing how the lessons were prepared, did not consult them before issuing the Bound Lesson circular. We sent a copy of this circular to Dr. Perrine, but have not heard from him in reply.

We enclose a copy of every circular issued by the Chicago School of Electricity.

Our course consists entirely of laboratory practice. Our instructors are thoroughly competent men. We have plenty of apparatus, of every description necessary, for the purpose of giving our students a competent electrical education, and as they are being promoted in their regular occupations it is sufficient proof that we are giving entire satisfaction to every one of them.

We can refer to every electrical enterprise in this city. We stand entirely upon our own reputation for doing good work, and do not advertise anything that is not strictly correct.

CHICAGO SCHOOL OF ELECTRICITY.
R. A. Bagnell, Manager.

Chicago, January 6, 1897.

MARRIED

MR. HOMER A. WADDELL, general superintendent of the Frick Coal and Coke Company's extensive telephone and telegraph service, at Scottdale, Pa., and Miss May Gertrude Thompson, daughter of J. Wilse Thompson, of Indiana, Pa., were married New Year's eve at the home of the bride.

MR. CLARENCE GAMER, general superintendent of the St. Charles Telephone Company, of St. Charles, Mo., was married to Miss Virginia Miller on Dec. 30, at the home of her parents, Jonesburg, Mo.

OBITUARY

A. LE ROY PAGE.

The death occurred on Jan. 2 at New Haven, Conn., from heart failure, of Mr. A. LeR. Page, manager for the Postal Telegraph Company in that city. Mr. Page was born in New Haven on the 16th of January, 44 years ago. With the exception of a stay of two years in New Rochelle, where he was manager for the telegraph company, he had never spent any considerable time away from his native city. He had been manager of the Postal Telegraph Company ever since it started a branch in New Haven. Previous to that he was operator for the Western Union Company, at the depot, and was at one time manager of the old Rapid Telegraph Company.

He was an active, energetic man, genial, and with qualities that made him many friends. There were few men in the profession in New England who were better known or more popular.

DEATH OF C. E. BALL.—The death was announced in New York City, on Jan. 3, of Charles E. Ball, of appendicitis, after a brief illness, at the age of fifty-one. He was a man with a wide reputation as an electrical inventor. At the outset of his electrical career he had much to contend with, especially in the introduction of his Ball "unipolar" arc lighting system, but he persevered, and after surmounting many obstacles he succeeded in establishing for himself an enviable position in the electrical fraternity.

PERSONAL

MR. C. B. WHITE, formerly with the Central Electric Co., Chicago, is now associated with the Walker Manufacturing Co., and is located at their Chicago office, in the Marquette building, in that city.

MR. FRANK BILLINGS, who is prominent in Cleveland manufacturing circles, as president of the Walker Company and as vice-president and treasurer of Billings, Taylor & Co., has also taken charge of the iron ore and pig iron business of Tod, Stambaugh & Co. Mr. Billings represents the interests of the estate of John Tod, late head of the firm.

A. M. ROBERTSON, general manager of the Minneapolis General Electric Company, was remembered New Year's day by the employés of the company, who presented him with a hunting case gold watch. S. P. Wright, chief engineer, made the presentation speech, and Mr. Robertson responded briefly.

MR. FRANK A. MAGEE, late with the E. S. Greeley & Co., has joined the forces of the Revere Rubber Co. Mr. Magee will no doubt find his large acquaintance and popularity among electric and railway men of great advantage to him in his new labors.

EDUCATIONAL

TWENTY-FIFTH ANNIVERSARY OF THE STEVENS INSTITUTE OF TECHNOLOGY.

A NOTEWORTHY event in the annals of technical education in the United States will be the forthcoming celebration of the 25th anniversary of the Stevens Institute of Technology, on the 18th and 19th of February next.

The festivities will consist of a banquet, at the Hotel Waldorf, New York, to which representative engineers and technical educators throughout the country will be invited. On the following day the Institute will be open for inspection, and the methods of instruction, together with the apparatus in the various laboratories, will be explained.

Not the least interesting feature of the exhibition will be the collection illustrating the work of the Alumni, and consisting of machinery, apparatus, drawings, etc., representing the product of their activity during the 25 years.

The festivities also include a reception, tendered to the faculty, graduates and undergraduates, by Mrs. E. A. Stevens, widow of the founder of the Institute, at Castle Point, Hoboken. A promenade concert and dance in the evening will conclude the celebration.

The Stevens Institute of Technology was founded by the late Edwin A. Stevens, of Hoboken, N. J., and in 1870 the erection of a building was commenced by the trustees, Mrs. E. A. Stevens, Mr. S. Bayard Dod and Mr. W. W. Shippen. Dr. Henry Morton, at that time Secretary of the Franklin Institute of Philadelphia, was tendered the presidency of the institute, and gathered a faculty of eight members about him. To this number others have from time to time been added, as the work of the Institute increased, until at the present time the faculty includes twenty-two professors and instructors. The total number of student graduates is 675, and the number in attendance during recent years has been about 260 each year.

The Stevens Institute has always taken high rank among the institutions devoted to technical education in the United States, and its 25 years of successful effort is amply exemplified in the work accomplished by its graduates in all departments of mechanical and electrical engineering.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

Alternating Currents :

ON THE DISTORTION OF ALTERNATING CURRENTS THROUGH UNSYMMETRICAL SELF-INDUCTION.—By Herman Eisler and Dr. Max Reithoffer. Three characteristic current curves are discussed: (1) When the magnetic core is air. (2) When the permeability varies. (3) Variations due to permeability and previous history of the iron. The article is to be continued. First section appeared in "Elek. Zeits.," Dec. 10, '96.

Central Stations :

ANNUAL REPORT OF THE ELECTRICITY WORKS AT DUSSELDORF. Current furnished during the past year has increased 19.1 per cent. At the end of the year there were connected 17;074 incandescent, 832 arc lamps, 25 motors. Income per kilowatt hour furnished the consumer was 59.48 Pfennig. For details, see "Elek. Zeits.," Dec. 10, '96.

Dynamos and Motors:

ARMATURE WINDING OF UNIPOLAR ALTERNATING CURRENT MACHINES.—By Koloman v. Kando. By unipolar winding author means stationary armature windings. The advantages claimed for these machines, concerning drop, are considered exaggerated. There are, however, decided advantages to these dynamos. A numerical example and actual calculation is given.—"Elek. Zeits.," Dec. 10, '96.

Electro-Physics :

DETERMINATION OF SPECIFIC HEAT BY MEANS OF THE ELECTRICAL CURRENT.—By A. Schlamp. This method consists in sending an electric current through two known resistances, which are immersed in two liquids in series.From the current strength and the heat developed in the two liquids, the specific heat of one can be found in terms of a function of the specific heat of the other.—"Zeitschr. f. Instr. Kunde.," Nov., '96.

Electro-Chemistry:

ELECTROLYTIC PROCESS FOR THE PRODUCTION OF COPPER, SILVER AND OTHER METALS.—By the Hoepfner process, which consists in leaching the powdered ores with a warm solution of perchloride of copper, containing also chloride of sodium or of calcium, pure electrolytic copper can be obtained directly from the ores containing any amount of impurities. 100 lbs. of copper can be produced with a consumption of 100 lbs. of coal.—"Eng. & Min. Journ.," Dec. 19, '96.

Measurement :

A DIRECT READING WHEATSTONE BRIDGE.—By A. P. Trotter. An improvement on the methods proposed by Swinburne.—"Zeits. f. Instr.," Nov., '96.

Mining :

ANACONDA COPPER MINING COMPANY, MONTANA.—The annual report almost in full in "Eng. & Min. Journ.," Dec. 26, '96.

Miscellaneous:

SAFETY RULES FOR HIGH TENSION INSTALLATIONS.—The various German electrical associations and societies in conjunction with some fire insurance companies have decided on a set of rules for wiring which have now been in use just one year. Editorially it is pointed out that all expectations for successful operations under the new system have been realized.—"Elek. Zeits.," Dec. 10, '96.

Power Transmission:

MAKING OR BUYING ELECTRICAL ENERGY ON A SMALL SCALE.—In reply to a question put to the editor of the paper at what point of consumption it is preferable to generate electric current on the premises, a number of engineers, whose names, however, are withheld, give their views. They all lean toward centralization for small plants, but agree that each case must be considered separately.—Lond. "Elec. Rev.," Dec. 25, '96.

Telephony, Telegraphy, etc:

COMMUNICATIONS BETWEEN COAST AND LIGHTSHIPS. An editorial comment on the failures of communications between coast and lighthouses without wires. The conductivity of the water according to Mr. Preece, was too great and interrupted the electric waves, thus performing the same function as an iron plate. An abstract of Prof. Blake's report published by the U. S. Lighthouse Board for 1895 is given in Lond. "Elec. Rev.," Dec. 25, '96.

INVENTORS' RECORD

CLASSIFIED DIGEST OF U. S. ELECTICAL PATENTS ISSUED DECEMBER 29, 1896.

Alarms and Signals:—

FIRE ALARM. J. A. McGahy, New York, 573,903. Filed April 30, 1896.

FIRE ALARM SYSTEM. A. C. Rogers, Plainfield, N. J., 573,924. Filed Jan. 25, 1896.

Means whereby the different fire stations and central office will be immediately notified of the number of the fire alarm box from which the alarm was turned in without having to wait until the gong in the station tolls off the number of the box.

ELECTROPNEUMATIC BLOCK-SIGNAL SYSTEM. A. H. Thorp. Toledo, O., 573,932. Filed April 10, 1896.

Details of construction.

FIRE ALARM. A. H. West, Lynchburg, Va., 573,944. Filed March 30, 1896.

Automatic system adapted for residences.

CIRCUIT CLOSER FOR ELECTRICAL ALARM CIRCUITS. J. C. Wollin, Williamsport, Pa., 573,948. Filed Sept. 11, 1896.

Especially adapted for use as a supplementary high and low water alarm for steam boilers.

PUSH BUTTON. G. Jepson, Meriden, Conn., 574,247. Filed Oct. 5, 1896.

Consists of a casing, a lever mounted in the casing and formed with oppositely inclined cam faces, two inwardly bowed fingers mounted in the case, one above and one below the cams, and overlapping each other in the path of their movement.

ELECTRICAL ANNUNCIATOR. R. L. Hunter and H. B. Higgins, Minneapolis, Minn, 574,327. Filed Nov. 19, 1895.

Adapted to be used with either an open or closed circuit battery.

Conductors, Conduits and Insulators; –

INSULATOR HANGER. R. Duncan, San Francisco, Cal., 573,966. Filed Dec. 31, 1895.

Consists of a flat piece of metal bent to fit over the flange of a metal beam, the hanger being retained on the beam by the horizontal tension of the wire.

INSULATOR. C. B. Martin, Schenectady, N. Y., 574,101. Filed Sept. 28, 1896.

Rail insulator for "third rail" systems.

TERMINAL FOR ELECTRIC CABLES. E. S. Reed, New York, 574,343. Filed March 29, 1892.

Dynamos and Motors:—

ELECTROMOTOR MAGNET. C. Partington, Newport, Ky., 574,215. Filed March 6, 1896.

An electromotor magnet with an armature at each end of the coil, each connected to a device which is moved by the two armatures simultaneously and conjunctively.

MOTOR GENERATOR. C. E. Scribner, Chicago, Ill., 574,278. Filed June 1, 1889.

Comprises a motor having a single closed coil armature and provided with two sets of brushes in combination with a main circuit through the machine, and a derived or local circuit connected with one set of brushes and a regulator connected with the local circuit to maintain a constant voltage in the local or working circuit.

Electro-Metallurgy :—

ELECTROPLATING APPARATUS. R. J. Marks, Hartford, Conn, 574,038. Filed Oct. 12, 1896.

A work holder comprising two adjacent relatively insulated conductive sections and two conducting hangers, one of which is connected to one section and the other of which is connected to the adjacent section at opposite ends.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. L. H Page, Chicago, Ill., 573,911. Filed March 12, 1896.

INCANDSCENT LAMP FITTING. A. Swan, New York, 573,929. Filed March 28, 1896.

The neck of an incandescent lamp provided with a bead of glass near the end of a metallic collar placed behind the bead, forming one of the lamp terminals.

SEARCH LIGHT. A. E. Colgate, New York, 573,962. Filed Dec. 24, 1895.

Feed mechanism.

ELECTRIC ARC LAMP. C. E. Scribner, Chicago, Ill., 374,045. Filed May 9, 1893.

Employs two pairs of carbons and an oscillating magnet placed in a permanent magnetic field whereby on the reversal of the current the arc will be shifted to the opposite pair of carbons.

ELECTRIC ARC LAMP. H. A. Seymour, Washington, D. C., 574,117. Filed June 30, 1896.

Enclosed arc lamp for alternating currents.

ELECTRIC ARC LAMP. H. A. Seymour, Washington, D. C., 574,118. Filed July 11, 1896.

Similar to patent below.

ELECTRIC ARC LAMP. H. A. Seymour, Washington, D. C., 574,119. Filed July 18, 1896.

An arc inclosing globe provided with a cover which is mounted upon and supported by the carbon holder.

ELECTRIC ARC LAMP. E. Thomson, Swampscott, Mass., 574,123. Filed Aug. 21, 1896.

Feed mechanism

ELECTRIC LAMP BASE. W. C. Bryant, Bridgeport, Conn., 574,301. Filed Oct. 31, 1896.

For use on lamp bases of the Thomson-Houston type.

Miscellaneous :

DENTAL PLUGGER OR MALLET. H. A. Edgecomb, Mechanic Falls, Me., 574,025. Filed Sept. 25, 1895.

Details of construction.

BULB FOR X-RAYS. J. Von Der Kammer, Chicago, Ill., 574,065. Filed March 17, 1896.

A bulb provided with cavities containing, respectively, the anode and cathode electrodes, being so arranged that they are presented in substantially the same direction.

ELECTRIC BRANDING STAMP. J. M. Kirker, M. Miller and J. A. Williams, Louisville, Ky., 574,203. Filed March 6, 1896.

Details of construction.

RACE STARTING MACHINE. W. Maxwell, St. Louis, Mo., 574,205. Filed June 29, 1896.

A suitable barrier movably suspended across the track and electrically operated mechanism for holding and releasing barrier.

APPARATUS FOR GENERATING OZONE. Marshall Pridham, Philadelphia, Pa., 574,341. Filed Oct. 15, 1896.

A combination of separated casings, one being dielectric, both provided with a coating of powdered conducting material. A brush discharge passes which traverses oxygen fed through the casings.

Railways and Appliances:—

DRUM FOR ELECTRIC CONTROLLERS. S. Harris, Johnstown, Pa., 573,874. Filed Oct. 6, 1896.

Embodies the use of pins extending upwardly and downwardly from the contact rings of the drum, and recesses on the top and bottom of the insulating disks of the recesses being adapted to receive the pins.

ELECTRIC LOCOMOTIVE. J. F. McLaughlin, Philadelphia, Pa., 573,905. Filed March 21, 1890.

Combines an electric motor with worms of different pitch, and gearing for the same, interposed between the motor and drive wheel axles, and means for coupling the motor and axles together through either worm gear.

ELECTRIC CAR BRAKE. E. A. Sperry, Cleveland, O., 574,120. Filed June 26, 1896.

Combined brake magnets, storage battery, circuit connections for supplying the magnets and the battery with current from the motor, a shunt round the battery, a high resistance solenoid in the shunt, and devices controlled by the solenoid for breaking the battery charging circuit.

ELECTRIC RAILWAY. J. A. Roche, Chicago, Ill., 574,171. Filed April 13, 1895.

Sectional conduit system.

MECHANISM FOR LOCATING AND DETERMINING DEFECTS IN RAIL BONDING. P. O. Keilholtz, Baltimore, Md., 574,333. Filed Feb. 29, 1896.

Comprising a series of contacts connected in pairs through potential indicating or recording instruments and electrical conductors, each pair of contacts being arranged to make sliding contacts at simultaneously corresponding points of a separate conductor.

TROLLEY. N. D. Stanley and J. S. Reynolds, Essex, Vermont, 574,345. Filed April 16, 1896.

Employs auxilliary trolley wheel controlled by the trolley rope.

CURRENT CONTROLLER OR RHEOSTAT. E. E. Werner, Dallas, Tex. 574,231. Filed June 22, 1896.

A cylinder having upon its periphery a substance composed of black lead and an alcoholic solution of shellac, with a brush adapted to travel laterally along the cylinder.

Regulation:—

APPARATUS FOR VARYING SPEED OF ELECTROMOTORS. L. Imhoff, Berlin, Germany, 573,979. Filed July 3, 1896.

Certain connections of switches and resistances which alter the number of active windings on the armature of the motor.

METHOD OF AND MEANS FOR REGULATING ALTERNATING CURRENT GENERATORS. B. G. Lamme, Pittsburg, Pa., 574,035. Filed March 11, 1896.

Consists in varying the slip of a non-synchronous motor driven by current derived from the generator and driving an exciting generator by such non-synchronous motor.

ELECTRIC WATER WHEEL GOVERNOR. A. Giesler, Dayton, O., 574,320. Filed April 20, 1896.

Employs a mechanical governor to control an electric current which operates the reversing mechanism to turn the gate in either direction.

VOLTAGE REGULATOR FOR DYNAMOS. T. M. Pusey, Kennet, Pa., 574,217. Filed May 22, 1896.

A brake regulated by the current is applied to the armature.

Secondary Batteries:—

ELECTRODE FOR SECONDARY VOLTAIC BATTERIES. G. A. Grindle, Prestwich, England, 574,322. Filed Oct. 13, 1896.

Consists of a rolled up strip of lead, having on its one side transverse ridges and furrows, all the ridges being connected by a central longitudinal ridge.

Telegraphs:—

KEYBOARD APPARATUS. F. R. McBerty, Downer's Grove Ill., 573,992. Filed Oct. 29, 1895.

Details of construction.

Telephones:—

AUTOMATIC TELEPHONE EXCHANGE SYSTEM. R. Callender, Brantford, Canada., 563,859. Filed March 19, 1896.

Comprises subscribers' lines and individual switches at which they terminate normally under the subscribers' control, and means for giving independent progressive motion to a switch on the reception of a preliminary impulse from the subscriber normally controlling it.

AUTOMATIC TELEPHONE EXCHANGE. A. E. Keith, Chicago, Ill., 573,884. Filed Sept. 16, 1893.

Means whereby the release mechanism of an exchange may be operated by a current of electricity controlled by the weight of the telephone receiver after it is hung up.

TELEPHONE CIRCUIT. C. E. Scribner, Chicago, Ill., 574,005. Filed April 20, 1895.

Circuit for telephones in which the transmitters are supplied with current over the line circuit.

TEST SYSTEM FOR MULTIPLE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 574,006. Filed July 5, 1895.

Embraces a visible and audible test signal to indicate to the operator making connection whether the line be free or not.

TOLL BOX FOR TELEPHONES. C. E. Scribner, Chicago, Ill., 574,046. Filed May 14, 1896.

A locking device for coin receptacles of telephone toll boxes designed to be controlled from the central station.

TELEPHONE EXCHANGE SYSTEM. C. E. Scribner, Chicago, Ill., 574,221. Filed June 6, 1894.

Automatic call and disconnection signals.

SELECTIVE SIGNAL SYSTEM. C. E. Scribner, Chicago, Ill., 574,222. Filed Jan. 8, 1895.

For use on party telephone lines.

SELECTIVE SIGNAL. C. E. Scribner, Chicago, Ill., 574,223. Filed Aug. 23, 1895.

Combines a ratchet wheel and pawl, means for imparting to the pawl successively a longitudinal movement radially to the wheel and then a transverse movement, a detent, and a link connecting the detent to be disengaged from the ratchet wheel during the transverse movement of the pawl.

SPRING JACK FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 574,224. Filed July 5, 1894.

Details of construction.

SIGNALING APPARATUS FOR TELEPHONE LINES. C. E. Scribner, Chicago, Ill., and F. R. McBerty, Downer's Grove, Ill., 574,225. Filed Aug. 17, 1895

Adapted for use on telephone lines carrying current for charging local storage batteries at the sub-station.

TELEPHONE SWITCH BOX. W. A. Houts, Parker, S. D., and L. G. Nilson, Sioux City, Ia., 574,245. Filed Aug. 25, 1896.

A mechanism whereby upon hanging up the receiver the parts will be automatically returned to a normal position.

TELEPHONE EXCHANGE APPARATUS. F. R. McBerty, Downer's Grove, Ill., 574,255. Filed May 25, 1896.

Means to permit the operator to send a call to both subscribers automatically in the process of making the connection.

SIGNALING CIRCUIT FOR TELEPHONE TRUNK LINES. C. E. Scribner, Chicago, Ill., 574,279. Filed May 14. 1896.

A device for preventing interference with the operation of the signals by currents arising from sources foreign to the signaling circuit.

AUTOMATIC SIGNALING DEVICE FOR TELEPHONE EXCHANGES. C. E. Scribner, Chicago Ill., and F. R. McBerty, Downer's Grove, Ill., 574,280. Filed Nov. 27, 1894.

A source of continuous current permanently connected with the plug circuit.

PLUG FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., and F. R. McBerty, Downer's Grove, Ill., 574,281. Filed May 31, 1894.

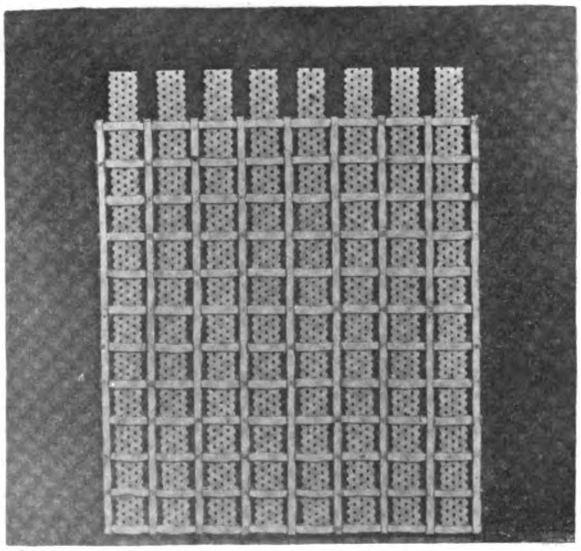
TRADE NOTES & NOVELTIES

THE ROONEY STORAGE BATTERY.

MANY devices have been contrived to lessen the weight of storage batteries by employing a grid made of insulating material to which the active material is applied, instead of employing a lead grid as is the usual practice. An ingenious arrangement of this nature is exhibited in the storage battery plate recently patented by Mr. John J. Rooney, of New York.

In the Rooney plate the grid is constructed by laying strips of wool felt in parallel rows lying in two directions at right angles to each other, so that the two sets or rows of strips form rectangular pockets or holes for the active material.

An odd number of strips is laid in one direction and an even similar in the other, the strips being of such a thickness that when pressure is applied in order to finish the grid, it will be of a uniform thickness. The strips are fastened quickly and inexpensively by a cementing composition, which is hard when cold, but softens under the influence of heat. This cement is painted over one side of the felt sheet, after which it is cut into strips.



ROONEY STORAGE BATTERY PLATE.

In building up the grid, metallic conductors are disposed between the even layers of felt, so as to lie along the middle of the holes or pockets formed in the grid. These conductors are never exposed to the electrolyte, except through the pellets of active material. Therefore in charging there is no shunting of the current at any point, but the entire flow must traverse the pellets of active material.

In order to secure the pellets in place, a perforated hard rubber or a metal sheet is folded over the pasted grid. When the latter is used, it is so put on that there is no metallic connection between it and the conductors inside the grid, for the reason previously explained.

These sheets are not fastened to the grids, but when the plates are assembled, the separators hold them rigidly against the pellets, the entire section, or element, being securely bolted. The expansion of the active material is therefore confined in the plane of each plate, tending to compress the felt and make secure contact with the conductors.

Owing to the porous nature of the grid, a large amount of electrolyte is absorbed, thus quickening the circulation throughout the mass of the pellets. Also the gases liberated around those faces, bordering on the felt, escape easily and in minute bubbles, so that high rates of charge and discharge may be used without detriment to the pellets. The felt grid, as it were, allows the cell to breathe and liberates the gases formed.

In building up the cell, the strips of felt and metallic conductors are guided and kept in place by a form, consisting of a base-plate having rows of vertical wire-pins, and provided with a false bottom or tray, which slides up and down on the pins. A large number of grids are built up on one form, and a top plate, of the same plan as the grid, is placed in position. The form is then placed in an oven, and when the cementing composition has sufficiently melted, pressure is applied and sustained until the cement has hardened. The tray is then lifted off with the empasted grids.

Grids constructed in this manner are very light, and the proportion of active material to conducting metal large, giving a high capacity per pound.

Owing to the non-conducting support, each plate may be transformed into a battery by reversing the polarity of the alternate rows of pellets. The plates may then be placed very close to each other without danger of short-circuiting.

Our engraving shows one of the Rooney plates constructed in the manner described.

THE BAILLARD X-RAY APPARATUS.

A NEW X-ray outfit has recently been put on the market by Mr. E. V. Baillard, of 106-108 Liberty street, New York, The distinguishing feature of the coils is their superior insulation. This feature is so marked that the coils average two inches of spark per pound of wire, a result far beyond the ordinary. This makes the internal resistance so low that the sparks are remarkably thick and fat and therefore very suitable for X-ray work. Additional length is given the spark by means of an ingenious modification of the vibrator whereby the current is allowed to attain its full value before breaking circuit and the time of breaking is much shortened. Two outfits are offered for sale, as follows: First, an exhibition outfit employing a fluorescent screen, and hood covering the observer; and second, a medical outfit using a fluoroscope. The latter is more convenient for general use, and the former for exhibition purposes where an admission fee is charged. Either of these coils will be furnished with a rotary circuit breaker and a variable condenser if so desired.

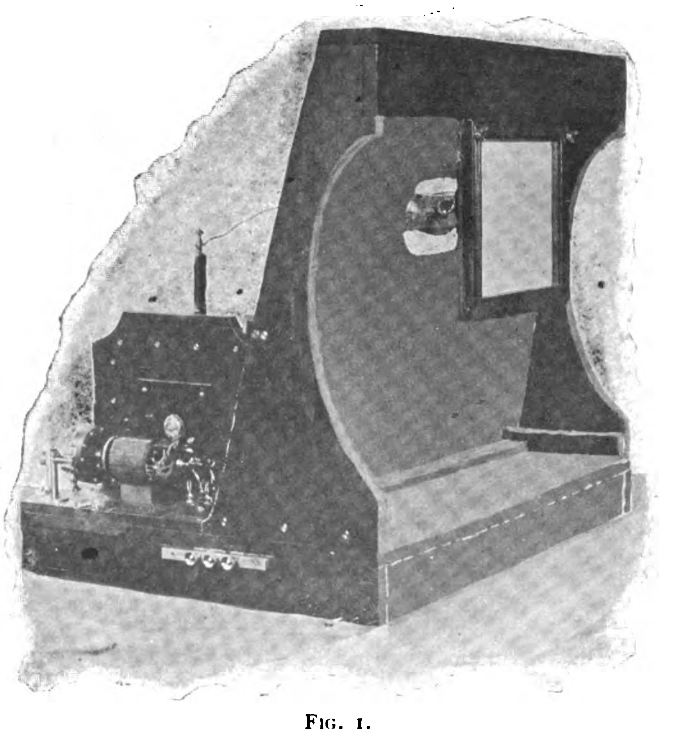


Fig. 1.

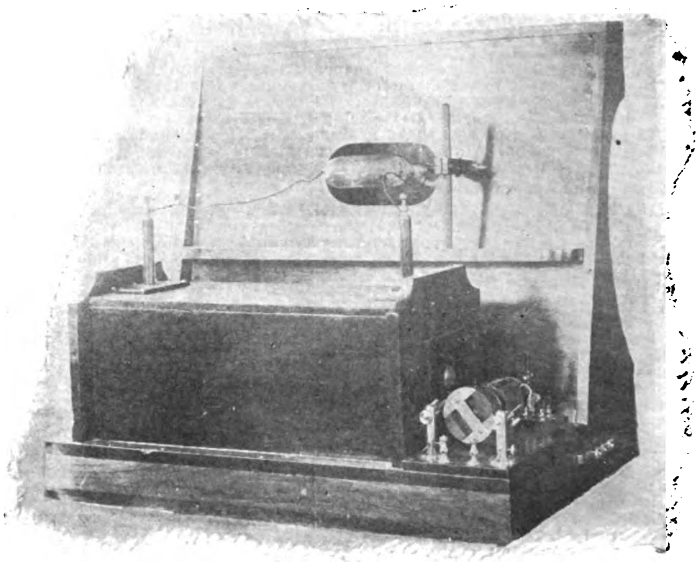

Fig. 2.

The tube used in these outfits is highly penetrating and examinations of the human trunk can be conducted with ease by its aid. The exhibition outfit is shown in two views in Figs. 1 and 2, and Fig. 3 depicts the medical outfit which is used for general experiment.

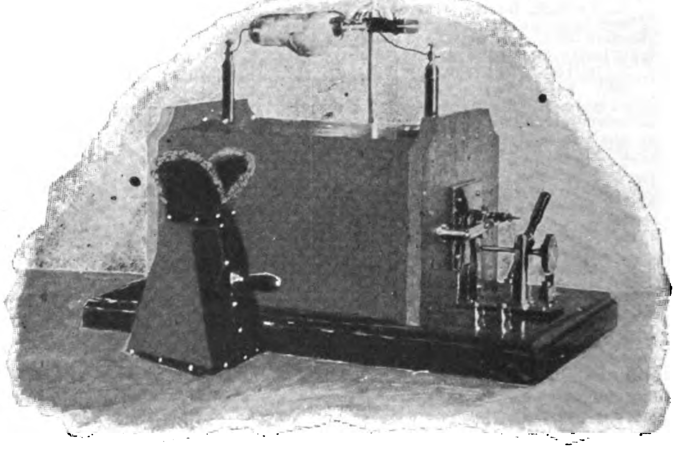

Fig. 3.

A $300,000 GENERAL ELECTRIC CONTRACT FOR POWER APPARATUS.

The General Electric Company has secured the contract for the machinery for the new power house of the Pillsbury-Washburn Flour Mills Company at the dam, Minneapolis, Minn. This award is a big plum for the company as the amount of the contract is in the neighborhood of $300,000. Seven sets of generative machinery will be installed at this time and three more will doubtless be added within a year or so. It is calculated that the seven will generate 7,000 horsepower, which will be more than sufficient to operate the street railway systems of the two cities of Minneapolis and St. Paul under ordinary circumstances.

G. E. NATURAL DRAFT HIGH POTENTIAL TRANSFORMERS.

ONE of the forms which the transformer for use with high voltage currents has taken is shown in the accompanying illustrations of the special "type H" natural draft type, developed by the General Electric Company, in its long distance transmission work. In transformers of this type the primary coils well taped and bound are insulated from each other by thick layers of felt; in that shown the primary coils are eight in number. Between the coils of the primary and the secondary winding an air space of one-half an inch intervenes. The whole is mounted upon a solid iron foundation and securely braced, and is then covered with a corrugated iron cylinder provided with a ventilating roof.

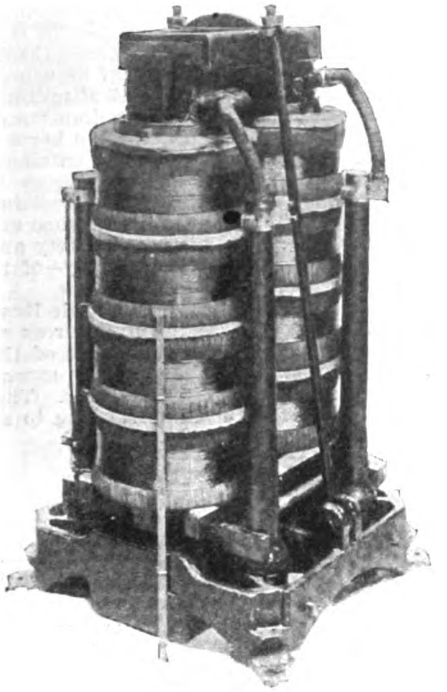

FIG. 1.—GENERAL ELECTRIC HIGH POTENTIAL TRANSFORMER.

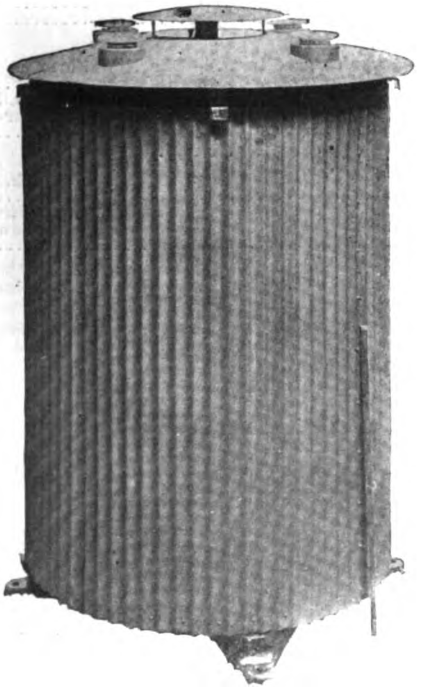

FIG. 2.—GENERAL ELECTRIC HIGH POTENTIAL TRANSFORMER.

One of the first transformers of this type has been for the past five months in service where it is necessary to reduce directly from 10,000 volts to 125 volts without intermediate transformers. It is used on the transmission lines of the Redlands Light and Power Company, at Redlands, Cal., to furnish low voltage current at a point some ten miles away from the substation secondary lines.

In the engravings, Fig. 1, shows the transformer open and Fig. 2 with the enclosing case.

WESTERN UNION NOT IN TELEPHONY.

Circumstantial statements having been printed in the Chicago newspapers as to the purchase by the Western Union Telegraph Company of the Western Telephone Construction Company, Mr. J. E. Keelyn, president of the latter, telegraphs us as follows: "Western Union Company has not purchased our company." This is certainly emphatic and final.

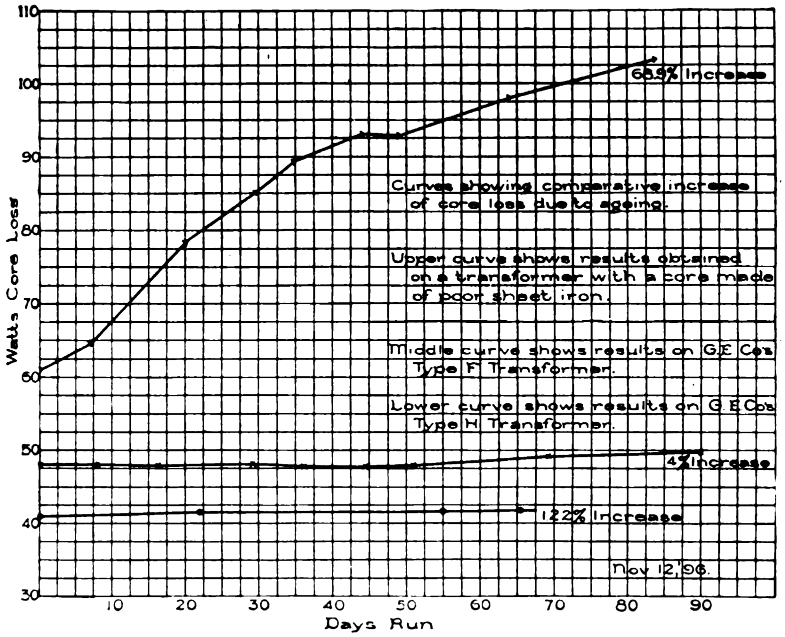
PACKARD LAMPS.

Notwithstanding the advance in the selling price of the standard makes of lamps, made necessary largely by the fact that the manufacturers have been operating under an actual loss for the past two years, the Electric Appliance Company report that the sales on Packard lamps have increased since the time of the advance, showing that their customers appreciate a good thing, and are willing to pay a fair price for a first-class article. The Packard lamp business has always been a very satisfactory part of the Electric Appliance Company's trade.

MAGNETIC FATIGUE OR AGEING OF TRANSFORMER CORES.

IT is now a well recognized fact that the loss in a given body of sheet iron subjected to a definite number of magnetic reversals per second and at a definite density of magnetization does not of necessity always remain the same. It is only by the greatest care that iron is brought into the condition in which it gives minimum loss when subjected to alternating magnetization, and the manner in which this result is obtained and the conditions to which it is subjected in actual use have both to be considered to insure keeping it in this condition.

Failure to properly consider these facts will produce a transformer which may give a fairly low core loss when first produced, but which after being in use for a short time will give a core loss 25, 50, or even 100 per cent. greater than at the start.



AGEING CURVES OF TRANSFORMER CORES.

This phenomenon is known as "ageing." The accompanying diagram shows a curve of actual results recently obtained on a 2,500 watt transformer of well-known make, tested by the General Electric Company, as a practical illustration of this fact. At the time of the last test the increase in core-loss, it will be seen, was 68.9 per cent. after a run of 90 days under normal conditions of commercial operation.

To reduce this loss in its transformers has formed the subject of exhaustive study by the engineers of the General Electric Company at Schenectady. The result of continued experiment allows this company to guarantee its transformers as free from the serious defect of "ageing"; in most cases absolutely negligible and in extreme cases not more than 4 or 5 per cent. On the same curve are given the actual results obtained on one of the General Electric standard type H 60-cycle transformers, and from this it will be seen that the loss comes within the above limit.

ADVERTISERS' HINTS

THE BOLGIANO MANUFACTURING COMPANY, 102 W. Pratt street, Baltimore, Md., will furnish one of their water motors at $5, which may be used for running revolving fixtures in show windows, sewing machines, small dynamos for electric power and light and a great many other purposes.

THE INTERIOR CONDUIT AND INSULATION COMPANY, 527 West Thirty-fourth street, New York, will send a sample of their new standard iron armored insulating conduit to those who request it.

THE WESTERN UNION TELEGRAPH COMPANY'S system includes over 800,000 miles of wire with 21,000 offices.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, publish a letter from a central station man in which he says of the Boudreaux dynamo brushes: "They are just the thing I have been looking for."

NEW YORK NOTES.

THE PURITAN ELECTRIC COMPANY, of New York, are having a very brisk demand for their alternating current arc lamp, which burns one hundred hours and is noiseless. They have already sold a large number of these lamps, their short length and grace of design commending them to all purchasers.

MR. SETH C. ADAMS, of the Bossert Electric Construction Company, of Utica, has been in the East for the past few days for the purpose of arranging agencies for the sale of their well-known specialties in wall outlet and junction boxes which they are now making of drawn steel. Mr. Adams has already arranged with the Bibber-White Company, of Boston, to represent them in New England.

THE AMERICAN ENGINE COMPANY, of Bound Brook, N. J., is about to ship one of its new American Ball engines to the Chinese government to be used in driving machinery for the coinage of silver.

WESTERN NOTES

MR. O. M. HUBBARD, manager, Electrical Department the Bradford Belting Company, Cincinnati, paid a visit to Chicago a few days ago, and reports that their New Year's business began under very encouraging conditions. They started out on January 2 by shipping some good orders, amongst them being an immense belt for the Peoples' Light and Power Company, Newark, N. J., which they claim is about as large a belt as has ever been made, being 80 inches wide, 3 ply and about 165 feet long. Mr. Hubbard is also very hopeful of a nice trade in their electrical supply business during the year 1897.

THE NATIONAL CARBON COMPANY, Cleveland, O., have sent out their calendar for 1897, it having, like its predecessors, a chromolithographic view of the huge works where they turn out so many varieties of carbon product.

EUGENE MUNSELL & CO., miners and importers of mica, Chicago, announce that they have moved into their new quarters at 117-119 Lake street. The increased facilities for handling their Western business will enable them to carry a larger stock of mica and drop forge copper segments, and thus place them in a position to fill all orders promptly. The Mica Insulator Company, of New York, Chicago, and London, announce that they also have removed their Western headquarters to 117-119 Lake street, Chicago, and are in a position to fill all orders for their "Micanite" specialties promptly. During the past year the company have enjoyed an increased trade in the West among the electrical manufacturers, electric railways and lighting companies.

MR. F. S. TERRY, of the Sunbeam Lamp Company, Chicago, has been a welcome visitor to New England and New York City.

THE CINCINNATI MILLING MACHINE COMPANY, of that city, have just issued and have sent us a copy of their catalogue devoted to an entirely new line of milling machines which they describe as possessing many important improvements incident to modern milling practice not heretofore introduced. They will be glad to send this catalogue to any address on application.

BRUNT & THOMPSON, the electrical porcelain manufacturers of East Liverpool, O., have sent us a huge chromolithographic calendar for 1897. The picture is pretty and shows a girl in big straw hat fondling a young puppy—of the dog order. The calendar is nearly two feet long.

BOILER SCALE.—The Pittsburg Boiler Scale Resolvent Co., of Pittsburg, Pa., will send free to any address on application a copy of their pamphlet on the subject of their admirable specific. The book discusses the subject, gives directions for use, and quotes a number of testimonials. The company will be glad also to answer questions relating to such steam engineering matters.

ELECTRIC LIGHTING

THE EVOLUTION OF THE ISOLATED ELECTRICAL PLANT DURING THE LAST FIFTEEN YEARS.—III.

(Concluded.)

CHARLES H. DAVIS.

FIXTURES.

AT first the electric lamps were placed irrespective of the location of the gas outlets and were hung on cotton cords, afterwards insulated with rubber and sometimes covered with silk. Adjustment was made by wooden hooked balls or wooden sticks, still in use. The desire to have the gas and electric lights on the same fixture led to "fixture attachments" with the flexible cord wound around the gas fixture or passing down the sleeve of the main stem and hanging below the body, and to which the lamp or cluster was attached. Soon "electroliers" came into use and "combination fixtures," also desk lights with patent shades, globes, etc., and horizontal, inclined, vertical and revolving shades and lamps; pendants of brass and iron tubes hung from a universal joint; patent loom fixtures and others for special kinds of work in breweries, factories, etc., in constantly increasing varieties. A constant source of annoyance and difficulty was the use of fuses in the base of the fixture; it was to avoid this that the idea of "panel boards" first suggested itself. To-day we use fixture boxes of iron with or without fuses as the case requires.

Modern Electric Elevator.

LAMPS.

The development of the lamp is most interesting. From the clumsy platinum filament to that of carbon; from the low voltage to that of the higher; from wooden bases to porcelain; from 6 watts per candle-power to 3.2 to 4 watts per candle power; from an average of a few hundred hours' life to 800 and 1,000.

MOTORS.

In the use of motors occurs one of the greatest changes, particularly on account of the large increase in capacity of plant required for their operation. The use of motors was confined, at first, to small fans used in the summer time, but now they ventilate, pump, run elevators, in fact, furnish the power required in all parts of our modern buildings. The engravings show several elevators of to-day.

CONTRACTS.

In the growth of this industry an interesting and remarkable change has taken place in the methods and requirements. Originally the manufacturers of dynamos undertook to build and install the entire plant; a new industry, undeveloped, and little understood by the buyer, and with large profits, enabled this to be done. The parent companies did the manufacturing, the engineering and the construction; competition soon caused absurd guarantees and bids on prominent buildings for advertising purposes, that caused enormous losses—in one case within the knowledge of the writer, $10,000, and in another over $20,000.

The purchaser soon found that the lack of individual responsibility of the manufacturing concerns who were constantly changing their managers (in one case within a week and frequently several times within a year), required the services of some one with equal knowledge to represent him; thus the growth of the consulting engineer's office. Furthermore, the enlargement of the electrical industry in all its branches was so enormous that the manufacturers were forced to decline undertaking contract work; they tried to avoid dropping this by construction departments and sub-construction companies, but the smaller office expenses and salaries on construction partnerships enabled the latter to obtain and control the business. While the owner can obtain a better and cheaper plant, if brought together properly, through a division of contracts under the main headings of engines, dynamos, switchboards, wiring, lamps and fixtures, yet a large majority of work let is placed by a bulk contract for the entire plant at an additional cost to the purchaser of from ten to twenty per cent.

LABOR.

In the old days one of the greatest sources of annoyance and loss both to producers and users was the lack of proper and skilled labor. Often the engineer had to show the employé of the manufacturer how to start and run his own machines;

foremen and superintendents were sent hundred of miles away from the factories to erect plants when they had only a week's experience with the apparatus to be used and knew little, if anything, about the requirements of wiring. The ordinary wiremen and helpers, employed locally by the foreman, were oftener day laborers than carpenters or men with some mechanical knowledge. These facts account largely for many evils existing during the growth of the business. Now, the question of labor is very different; the men are better trained, more experienced, and through the labor unions (whatever may or may not be their other merits or demerits) are given a longer and better schooling before they are allowed to undertake work that requires skill and judgment; this is one of the most important advancements during the existence of isolated plant work.

Modern Electric Elevator.

COST.

The change in cost of apparatus and supplies is probably greater than those unfamiliar with ancient electrical history realize. In 1880 a plant was purchased from the Edison Company and shipped to Lake Superior, its capacity was 100 16-candle-power lamps and it consisted of dynamo, regulator (rheostat), ammeter, indicator (voltmeter), base frame, lamps and sockets, for the sum of $2,000 f. o. b. works of Edison Company. In 1887 the same plant, but better apparatus from the same sampany could be bought f. o. b. factory, for $800, and to-day the slower speed heavier constructed dynamo can be purchased for $400, f. o. b. factory, while a direct-connected 300 r. p. m., 25 kilowatt (400 lights) dynamo costs to-day $800, f. o. b., factory. Lamps of 16 candle-power which then sold at $1.25 each, now sell for 16 cents and are much better. Sockets at $1, now ten to fifteen cents. Cut-outs from several dollars down to under one dollar, switches the same.

THE FUTURE.

The future development of the isolated electrical plant (outside of radical changes that would occur through discarding the use of steam as a motive power) in large buildings will undoubtedly be towards the discarding of all use of gas, of steam or water heating (this is somewhat problematical as today low temperatures are best produced by water, steam or air while high temperatures are more easily accomplished by electricity), of hydraulic elevators, steam pumps and all small steam apparatus, all of which will be replaced by electric heating and motor devices. Furthermore, the future will see the use of higher potentials, say, up to 220 volts, by the perfection of the higher voltage lamps; the use of such a system would solve many problems, such as the conversion of existing large installations using street current on the three-wire system to isolated plants as a matter of economy, the reduction in size of wires and tubing to more easily conceal them, and the great reduction in first cost of all apparatus and material.

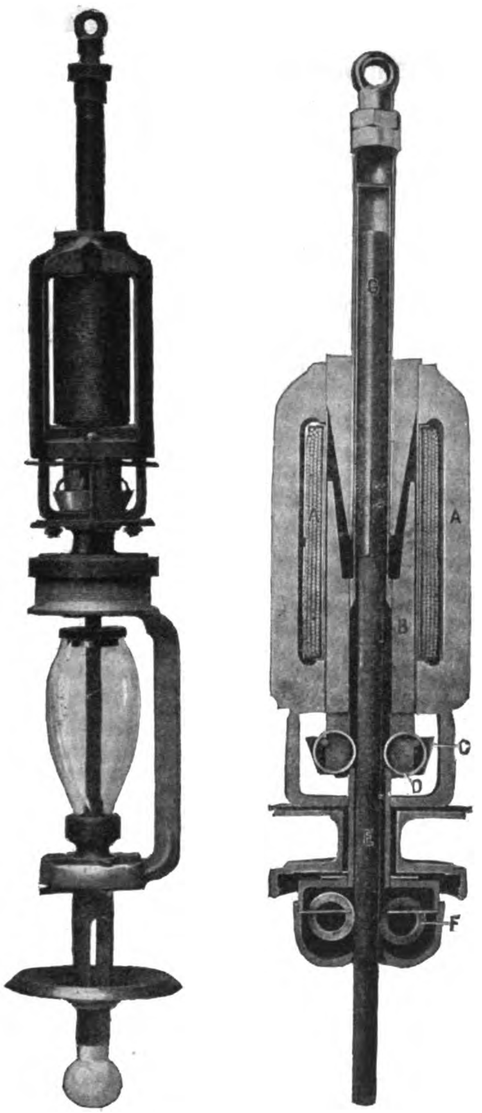
THE MANHATTAN ENCLOSED ARC LAMP.

Although Manhattan enclosed arc lamps are met with everywhere, the construction of the mechanism of the lamp is not as well known as it should be. The lamp embodies a number of exceedingly novel features which have not heretofore been described. Our engraving, Fig. 1, shows the Manhattan lamp complete. It will be noted that the beauty of the lamp is greatly increased by doing away entirely with the carbon rod and making the length of the lamp in keeping with its other proportions. In the Manhattan lamp the upper carbon,

The Manhattan Enclosed Arc Lamp.

extended by a thin metal sheath, is fed directly through the mechanism.

The outer globe is airtight at all points, except at the bottom, where there is a hand-hole large enough to permit of trimming the lamp and cleaning the globe. This hand-hole is closed by a yielding pan. The outer globe is permanently secured to the frame of the lamp, and the top opening made airtight with asbestos gaskets.



FIGS. 2 AND 3.—MECHANISM OF MANHATTAN LAMP.

In Fig. 2 is shown a lamp with the shell and outside globe removed, and Fig. 3 shows a section of the body of the lamp with the bracket and lower carbon holder also removed.

In Fig. 3, A is a solenoid; B is its armature. Attached to this armature is a pan C in which are placed four clutch rings D, which extend through openings in the armature, and clutch the carbon E or carbon sheath G direct; F shows the brush box, in which are laid 21 rings; these rings bear against the carbon by gravity, and make 21 points of contact, feeding the current to the carbon. The action of the lamp is extremely simple.

The armature is held in suspension when the lamp is burning, and is raised or lowered according to the variation of the resistance across the arc. The raising of the armature causes the clutch rings to grasp the carbon, and when lowered loosens the clutch rings, which allow the carbon to descend until the resistance across the arc is again equalized. It will be seen that, practically, the entire moving mechanism of the lamp consists of the armature, which is a solid piece of tool steel weighing 3½ pounds, and the 4 clutch rings stamped out of brass. The lamp is entirely without springs or adjustments of any description.

The lower part of the yoke, in the shape of a ring, admits the arms of a spider on the lower carbon holder. This spider secures the lower carbon holder in the yoke and closes the circuit through the lamp.

As will be seen in Fig. 3, the carbon sheath is slightly larger than the carbon. The opening in the inner globe cap is of such size as to readily admit the upper carbon, but will not allow the carbon sheath to pass through, so that when the upper carbon has burned to the proper limit the arc lengthens and cuts out the lamp automatically. When the lamp cuts out it leaves 5 inches of the upper carbon in the sheath. This stub is used as a lower carbon in the sheath. This stub serves as a lower carbon for the next run, so that 150 hours' life is obtained from a total of 12 inches of carbon.

ENGLISH INCANDESCENT LIGHTING STATISTICS.

WHAT make in many ways a remarkable showing, are the statistics of the growth of electric lighting in London and the provinces..This is illustrated in the accompanying diagrams taken from the London "Electrician."

The Metropolitan Electric Supply Company still continues to lead the way in the matter of lamp connections in London, its 1895 total of 257,000 having been increased to 310,000 during 1896. Not only does this concern continue to lead the way, but its curve (see Diagram 1) shows no signs of that bending over which is so marked a characteristic of that of the Westminster Electric Supply Corporation. The rate of progress of the city of London Electric Lighting Company, also, is well maintained; indeed, its curve runs sensibly parallel to that of the Metropolitan Company. After these three giants we come, after a big descent, to the London Electric Supply Corporation. The great majority of the companies, the curves of which are so uncomfortably crowded together at the bottom of the diagram, appear to be making healthy progress; that is to say, only one or two concerns show signs of having exhausted their territory.

From Diagram 2 it will be seen that the provincial electric lighting undertakings have during 1896 caught up and passed the metropolis in the matter of lamp connection; the total for London being 1,462,000, that for the provinces being 1,602,000, so that the grand total for the United Kingdom is now well over three million 8 candle-power lamps.

In Diagram 3 we give a graphical representation of the favor relatively enjoyed by the alternate current and continuous current systems. From this and Table I. it will be seen that the United Kingdom is now about equally divided on this point.

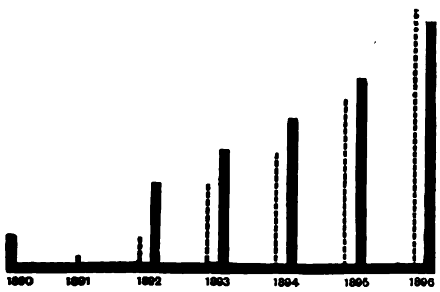


DIAGRAM 2.—Lamp Connections of London and Provinces.
London ▬▬ Provinces - - - -
Scale (approx.), 1 inch = 800,000 8 c.p. lamps.

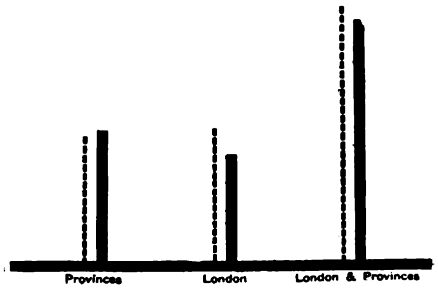

DIAGRAM 3.—Alternate-current (- - - - -) Continuous-current (▬▬)
Scale (approx.), 1 inch = 800,000 lamps.

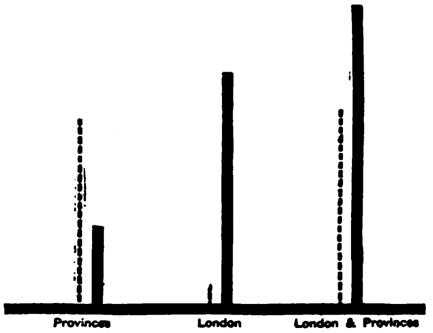

DIAGRAM 4.—Municipal (- - - - -) Company (▬▬)
Scale (approx.), 1 inch = 800,000 lamps.

ENGLISH ELECTRIC LIGHT STATISTICS.

In London the municipalization of the electric light makes but microscopic progress; in the provinces, on the other hand, its advance is rapid, the municipal lamp connection at the end of 1896 being 55 per cent. greater than it was at the end of 1895, an advance due to some extent to the conversion of Liverpool, Southampton and Exeter to the municipal faith.

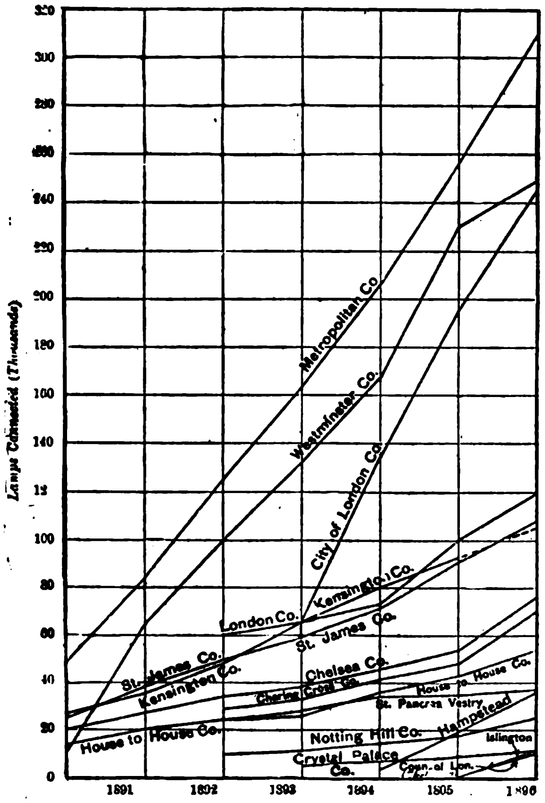

Diagram I.—Lamp Connections of the London Companies

English Electric Lighting Statistics.

The tables (I. and II.) given below state in figures what the diagrams (3 and 4) set forth graphically.

Table I.—*Alternate-current and Continuous-current Lamp. Connections.*

—	∽	—	Totals.
London	792,000	670,000	1,462,000
Provinces	778,000	824,000	1,602,000
Totals	1,570,000	1,494,000	3,064,000

Table II.—*Municipal and Company Lamp Connections.*

—	Municipal.	Company.	Totals.
London	84,000	1,378,000	1,462,000
Provinces	1,126,000	476,000	1,602,000
Totals	1,210,000	1,854,000	3,064,000

NEW YORK CITY ELECTRIC LIGHT AWARDS.

The Gas Commission have awarded contracts for lighting the city for the coming year to the following companies:

	Lights.	Nightly Cost.	
Brush Electric Co.	771	40c.	$112,566.00
Mt. Morris Electric Co.	519	40c.	75,774.00
Harlem Electric Co.	66	40c.	9,636.00
Manhattan Electric Co.	728	40c.	106,288.00
Edison Electric Co.	208 double	50c.	37,960.00
Edison Electric Co.	233 single	40c.	34,018.00
North River Electric Co.	934	45c.	153,409.50
Total			$529,751.50

The city expenditure for street gas lamps will be $472,843.

MISCELLANEOUS

THE THEORY OF THE WIRING TABLE.[1]

BY THOMAS G. GRIER.

THE theory of the wiring table is simply one of proportioning resistances. The first point to be considered is, how is the resistance varied in any substance? The law states that the resistance of any substance varies directly as its length and inversely as its cross section. This law has been verified by experiment and is universally accepted as a law of nature.

The resistance varies directly as the length of any given substance, means that if the length of a wire is doubled, the resistance is doubled, and three times the length means three times as much resistance.

The resistance varies inversely as the area of cross section, means that if the area of a wire is doubled, that is, if there is just twice as much metal for a given length of wire, the resistance is decreased one-half. If the area is increased three times, the resistance is decreased to one-third. In a wire of a given substance if the length is doubled, and at the same time the area is doubled, the resistance remains the same, or if the length is increased to three times as great, and at the same time the area is increased three times, the resistance remains the same.

From this application of the law already referred to, it can be seen how it is possible to vary the size of a wire so that the resistance remains constant for any length, or how the resistance may be changed to suit any condition or circumstance.

The next consideration is the action of the electric current. The pressure is measured in volts, and the rate of flow is measured in amperes. The volts are all used up in forcing the amperes against the resistance.

The resistance, if it were all in the wires, would mean a total loss of the electrical energy, because the volts would be used in doing work from which no results were obtained. It is necessary, therefore, to make the resistance of the wire which conducts the current but a proportion of the total resistance. The rest of the resistance of a circuit being that which exists in the lamps and the other devices or apparatus which convert the electrical energy into commercial forms, as light, power or heat.

To so compile a table and calculate the sizes it is necessary to consider the relation which exists between the unit of resistance, the ohm; the unit of pressure, the volt; and unit of current, the ampere.

One ohm resistance requires the pressure of one volt to transmit one ampere. Two ohms require two volts to transmit one ampere. One volt will transmit but one-half an ampere over two ohms, and 100 volts will transmit ten amperes over ten ohms.

This is Ohm's law, which, when given in the form usually found in text books is as follows: The rate of flow, or current, measured in amperes, is equal to the volts divided by the ohms. The volts are equal to the amperes multiplied by the ohms, and the ohms are equal to the volts divided by the current flow or amperes.

Knowing the relation of resistance to the flow of currents, and the pressure, the next point to be considered is the substance used for the wires, and ascertain the amount of its resistance for a given length and size, to be used as a unit for making the calculation necessary in compiling the table.

Copper commercially and physically represents the best conductor for the transmission of the electric current. A dollar's worth of copper will conduct a greater amount of electric current than any other metal of equal value with the same loss of energy. In the illustrations following, copper will be the substance considered, as the wiring tables used for ascertaining the size of wire are for copper wire.

The units by which wire is measured are the circular mil and the foot. The circular mil is the area of a circle whose diameter is one one-thousandth of an inch. The foot is a unit familiar to all.

The unit of wire then, would be a wire one foot long, the area of which is one circular mil, and the resistance of this unit of copper wire is between 10 ohms and 11 ohms, depending upon the temperature of the wire.

Ten and six-tenths (10.6) ohms may be assumed as the resistance which approximates closely to the average at ordinary temperatures. Taking this as the basis for compiling a wiring table, it is known that to send an ampere through this unit of wire would require 10.6 volts. For, as stated in Ohm's law, the volts must equal the ohms multiplied by the amperes. But in everyday problems, the known quantities are the volts and amperes, and the calculation is to find wires of proper resistance to suit the conditions. The resistance, or the ohms, must equal the volts divided by the amperes. To solve this problem, the volts are divided by the amperes, and we have the resistance.

---

[1] Abstract of a lecture delivered before the Chicago School of Electricity.

The resistance varies as the length and inversely as the area. It is the area of a wire which is desired, and one the resistance of which will equal the resistance found by dividing the volts by the amperes. The resistance of one foot of copper wire, one circular mil in area, equals 10.6 ohms. The resistance of any wire is equal to its length multiplied by 10.6 and this divided by the area. Now, it is known that the volts divided by the amperes equals the resistance, and the volts divided by the amperes are therefore equal to the length of the wire multiplied by 10.6 and divided by the area.

In any problem of wiring we have the number of volts and amperes, also the distance the current is to be transmitted, and the only thing remaining to be found is the area. To find this, we multiply 10.6 by twice the distance or the total length of wire (in multiple arc work there is one outgoing wire and the return circuit, which makes the total length of wire double the distance), and multiply this by the amperes, and divide the product by the volts used, which gives the area of the wire.

The volts used are not the total volts of the system, but the volts lost in the wire. If the problem is given as so many per cent. loss, it would mean a per cent. of the total number of volts. To illustrate: If the wire is to use up 2 per cent. of the pressure, and the voltage of the system was 50, then you would divide by 2 per cent. of 50 or one volt, or, if the pressure was 100 volts, you would divide by 2 per cent. of 100 or 2.

In compiling a table, let it be assumed for a 50 volt system for a regular increase of distances of ten feet, the following method is pursued: First, the per cent. loss is ascertained, let it be 2 per cent. This then would be one volt. Then one ampere will be considered, first, as the total current flow, and the following calculations would be made: 10.6 would be multiplied by 10 feet and by 2 to get the length of wire, and this multiplied by 1 ampere and the product divided by volts lost, or in this case, by one which would give us an area of 212 circular mils. This would be the size of a wire necessary to allow one ampere to be transmitted 10 feet with one volt loss (or 2 per cent. of 50 volts).

The next calculation would be for 20 feet distance, and as the resistance of the wire must remain the same, the area first found, namely, 212 circular mils, must be doubled as the distance has been doubled. For 30 feet to keep the resistance constant, the area is increased three times, and so on, until the limit of the table, say 200 feet, is reached, when the area will be increased 20 times, as the length has been increased by that amount.

Then the same method will be continued for two amperes, namely, multiplying 10.6 by the distance and by 2 to get the length of wire, and this multiplied by amperes and the whole divided by the volts lost. This is continued until the area for all the wires for each of the distances and for the various number of amperes have been determined.

As it is necessary to multiply 10.6 by the distance, multiplied by 2, in every instance, 2 × 10.6 or 21.2 is used instead, and the straight distance used. The whole resolves itself into the simple formula:

$$\frac{21.2 \times \text{distance} \times \text{amperes}}{\text{Divided by volts lost}} = \text{area of wire in circular mils.}$$

When these areas are found, the commercial sizes of wire are inserted in the table which are nearest to the size found, but always larger, never smaller; that is, if the area found in the calculation came between a No. 0 wire and a No. 00 wire, the No. 00 wire would be the size used in the table.

CARVINGS AT THE STATE CAPITOL.

Among the forty heads carved in the cluster capitals on the grand stairway of the State Capitol at Albany are those of Benjamin Franklin and Joseph Henry.

DAVY-FARADAY RESEARCH LABORATORY.

This laboratory was opened on January 18. Under the deed of trust, workers in the laboratory are entitled, free of charge, to gas, electricity and water, as far as available, and, at the discretion of the directors, to the use of the apparatus belonging to the laboratory, together with such materials and chemicals as may be authorized. All persons desiring to be admitted as workers must send evidence of scientific training, qualification, and previous experience in original research, along with a statement of the nature of the investigation they propose to undertake.

The laboratory is attached to the Royal Institution, London.

ELECTRICITY IN NAVAL LIFE.—XIV.

BY LIEUT. B. A. FISKE, U. S. N.

CARE OF THE ELECTRIC INSTRUMENTS.

THE principal enemy of the electric instruments is the same as that of all other instruments used on shipboard, namely, sea air and moisture. For this reason, the galvanometer cases should not be opened, except when necessary, and should be left open as short a time as possible.

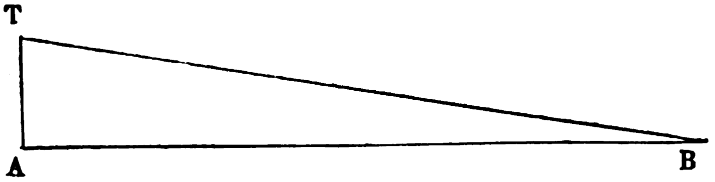
In case of any trouble whatever with any of the electric instruments, the cause will be, in nine cases in ten, due to a broken wire or connection, or else a connection is faulty, that is, neither firmly made nor completely broken. If the connection is completely broken, a galvanometer will not move at all; but if the connection is merely faulty, the resistance of the connection will vary between infinity and some very small quantity, and cause an oscillation of the galvanometer needle. This may appear periodically, as the rolling of the ship from side to side brings the two loose contacts against or away from each other; or it may occur irregularly and be due to unnoticed causes, such as draughts of air, manipulation by the hands of the operators, or other causes tending to make the loose contacts touch and let go. The remedy is to examine all contacts and connections, and make them firm.

THE STADIMETER.

The stadimeter was introduced originally as an adjunct to the range finder, and designed to be used in concert with it, in such a way as to combine the portability and convenience of a one-observer instrument with the accuracy of a two-observer instrument.

But it has a distinct field of its own in navigation, fleet tactics, torpedo boat work, and wherever it is desired to know the distance of an object whose height, or length, or breadth is known; or where it is desired to know the height, length, or breadth of an object whose distance is known, the micrometer head M being graduated in yards of distance, the index bar B being graduated in feet, representing the height, length or breadth of the object.

As will be seen from the drawing, it is a modification of the sextant. It is, moreover, of the same size as the ordinary sextant used in ships.



Clearly, from the diagram,

$$AT = BT \text{ sine } ABT\text{; or}$$
$$BT = AT \div \text{sine } ABT.$$

So that in either case the measurement involves the measuring of sine ABT.

To accomplish this with the stadimeter, bring the reflected ray from the top of the object into coincidence with the direct ray from its bottom, by moving the index bar which carries the index glass I on its pivot, in the same manner as in using the sextant. To move this index bar, rotate the micrometer head M. The sine of the angle through which the index glass has been moved is clearly the amount by which the micrometer screw has moved longitudinally, divided by the distance from the pivot of the index bar B to the point on its edge where the force of the micrometer screw is applied. The German silver spring G presses the index bar against the end of the micrometer screw, and prevents lost motion.

Now, by the theory of the sextant, the angle between the reflected ray from the top of the object and the direct ray from the bottom of the object is twice the angle through which the index glass has been moved out of parallelism with the horizon glass H. Therefore, assuming that for such small angles as those here used the sines of angles are proportional to their arcs—

$$AT = BT \times 2 \times \frac{\text{Length of movement of micrometer screw}}{\text{Distance from pivot to point of application of screw on index bar.}}$$

or,

$$BT = AT \div 2 \times \frac{\text{Length of movement of micrometer screw}}{\text{Distance from pivot to point of applica- of screw on index bar.}}$$

As the length of movement of the micrometer screw longitudinally can be determined by the amount of angular movement of the micrometer head, it is plain that, if we know the pitch of the micrometer screw, the micrometer head can be graduated in units of distance and the index bar in units of height, or vice versa.

In the stadimeter this is done, and furthermore the point of application of the micrometer screw on the index bar can be varied at will. This is accomplished by mounting the micrometer screw on a block or nut which rides on the long screw S, so that by turning S the block or nut is moved in either direction.

To use the stadimeter to measure the distance of an object whose height is known, set the micrometer screw opposite that graduation on the index bar which indicates its height in feet, and bring into coincidence the reflected image from the top of the object and the direct ray from its bottom. The distance of the object in yards will then be found opposite the pointer on the micrometer head.

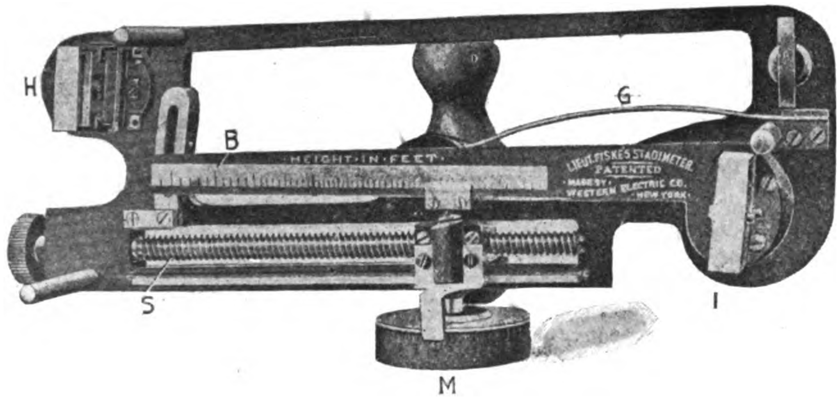
To measure the height of an object whose distance is known, assume the height to be 100 feet, and set the micrometer screw at the 100 mark on the index bar. Proceed as before, and read off corresponding distance (which may be called D) upon the micrometer head. Obviously,

$$\text{True height} : 100 = \text{true distance} : D.$$

$$\text{True height} = 100 \times \frac{\text{true distance}}{D}$$

The stadimeter may now be set at the true masthead height and used as explained before.

When employed in connection with the range finder in a naval battle, take the distance of the enemy with the range finder very carefully before the action has become hot, bringing her as nearly abeam as convenient, and when distant, say, 2,500 or 3,000 yards, find out her masthead height simultaneously with the stadimeter, and set the stadimeter at this height and keep it ready for use. If afterwards the range finder becomes disabled, or if it cannot be used for any reason, proceed with the stadimeter.



STADIMETER.

A moderately skilled observer can get eight observations per minute.

The foretop is a good place in which to use the stadimeter, the observer being connected by speaking tube, telephone, or range indicator with the person who telegraphs the ranges to the guns.

In fleet actions endeavor, if possible, to get exactly the masthead heights of all the enemy's ships and make a memorandum, to be used when required.

The manner of using the instrument is the same as that of the ordinary sextant, as are also the precautions to be observed regarding the parallelism of the mirrors.

To make the horizon glass parallel to the index glass, when the micrometer reads INFINITY, move very gently the two set screws at the bottom of the horizon glass, slacking one screw and screwing up the other, until the direct and reflected images of a distant object coincide. In using these screws remember that the reflected image seen in the mirror of the horizon glass goes in the direction in which the screws are advanced. If, for instance, the reflected image is below the direct image, screw up the lower screw and slack the upper one. Whereas, if the reflected image is above the upper one slack the lower screw and screw down on the upper one. Do not turn the micrometer head on its screw to accomplish this purpose.

When a very careful observation is desired, as in navigation, it is very desirable to assure the parallelism of the horizon and index glasses after the carriage has been set at the proper height.

Be careful not to force the micrometer head to turn, in case it turns hard, because the reason for its turning hard will be that the micrometer screw is clamped; and if force is used, the head may turn around independently of the micrometer screw. For this reason do not clamp it unnecessarily tight, and do not clamp it at all unless necessary.

The micrometer head is secured to the micrometer screw by the friction of three stout set screws, in such a position that when it reads INFINITY, the edge of the index bar is parallel to the slot along which the micrometer carriage moves on the long screw. If the horizon glass is adjusted to parallelism with the index glass when the micrometer reads INFINITY, and when the micrometer screw is set opposite any height graduation (say 200), the mirrors will remain parallel if the screw is moved opposite any other height graduation (say 60); because the index bar remains parallel to the movement of the micrometer carriage. But if, from accident, the micrometer head is forced to turn independently of the micrometer screw, then when the micrometer reads infinity, the screw will have placed the index bar at an incorrect distance from the long screw, so that if the horizon glass be made parallel to the index glass when the screw is opposite any height graduation, and if the carriage be then moved opposite to another height graduation, the index bar will also move and the parallelism of the mirrors will be destroyed.

This contingency is not probable, but in case it occurs, the micrometer head can be returned to its correct position on the screw by slacking the set screws and turning the head around till the adjustment marks scratched on the screw and the micrometer head near the set screws come opposite each other.

In case some accident should befall the instrument such that a total readjustment of the micrometer head on its screw becomes necessary, also to adjust during manufacture, proceed as follows:

Place the screw opposite 200, align the index bar approximately by eye, slack up the three set screws, make the micrometer read infinity, and reclamp the set screws. Make the mirrors parallel by moving the horizon glass, until the direct and reflected rays from a distant object coincide, as in adjusting a sextant. Move the micrometer carriage down to 60. Bring into coincidence the direct and reflected rays from a distant object, by turning the micrometer head.

If when the carriage is moved down to 60, the infinity mark on the pointer, it is because the index bar has moved further away from the long screw, showing that when the micrometer head was at infinity and the screw was at 200, the screw was forcing the index bar too far; so that when the screw got down to 60, and was further away from the pivot of the index bar, it did not force the index bar so far, and hence the micrometer head had to be turned to the right, bringing infinity to the right of the reference mark, in order to bring the index glass back to parallelism with the horizon glass.

If when the carriage is moved down to 60, the infinity mark is to the left of the reference mark, when the mirrors are parallel, the same reasoning shows that it is because the then existing position of the micrometer screw does not force the index bar far enough away.

Therefore, in the first case, when the mirrors are parallel, the screw is too far advanced; and in the second case, too little advanced.

If on going to 60 the distance in fractions of an inch that the infinity mark is to the right of the reference mark is A, turn the micrometer screw until the mark is about ⅓ A to the left of the reference mark and clamp the micrometer screw. Go back to 200 and make the horizon glass parallel to the index glass. Go down to 60. If now, in order to make the index glass parallel to the horizon glass, the infinity mark must still be moved to the right of the reference mark, the infinity mark must be moved farther to the left of the reference mark than it was just placed, and the above operation repeated. But if the infinity mark is found to the left of the reference mark, the micrometer head has been moved a little too far to the left of the reference mark and must be moved back a little, and above operation repeated.

If on going to 60 the first time, the infinity mark is found to be to the left of the reference mark, a distance equal to A, the infinity mark should be moved about ⅓ A to the right of the reference mark, the screw set 200, mirrors made parallel, and the same operation followed as above outlined, until the mirrors remain parallel when the micrometer carriage is at 200 and at 60.

If, when the screw is opposite graduations below 100, the variations from infinity are not more than $^1/_{32}$ inch, the error is negligible for practical purposes.

When the proper position for the micrometer head on its screw has been found, clamp the micrometer screw, slack the three set screws on the micrometer head, turn the micrometer independently of its screw until infinity mark is opposite the reference mark, tighten the set screws carefully and then unclamp the micrometer screw.

In case the known height of an object is more than 200, set the screw at 200, and measure the distance correspondingly, which may be called C. Now D, the true distance, is found as follows:

$$D : C = \text{True height} : 200$$

$$D = \frac{C \times \text{True height}}{200}$$

The stadimeter has been issued to nearly all our ships in commission; the New York, being a flagship, has two. The Texas has one for ordinary ship work, and another for use in connection with the range finder, the idea being that constant use of a stadimeter often in the rain, while not impairing its value seriously for use in fleet tactics, will injure the mirrors materially for fine gunnery work between 2,500 and 3,000 yards.

Note.—Some later instruments are made of an alloy of aluminum and nickel, which is very hard and durable. The weight of a stadimeter made of this alloy is less than two pounds.

ANOTHER UNIPOLAR MACHINE THAT WILL NOT WORK.

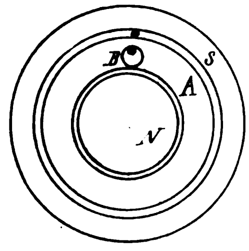
By JOHN R. MARKLE.

EXPERIMENTS made by Mr. Albert Hemingway and myself during several years past have suggested that an electric generator of the unipolar type, consistently based upon the theory of cutting lines of force could be constructed, that would afford a high e. m. f.

The basic principle involved was to be that of connecting the inductors in series by conductors so placed on the armature core as to partially evade the magnetic lines, or in other words, permit them to leak by or around the conductors.

Reference may first be had to the Siemens improved unipolar machine, consisting of a tube, or series of tubes revolved between the poles of an electromagnet, one pole of which completely surrounds the outer circumference of the tube, the magnetic lines passing radially through the tube to the other cylindrical pole within the tube.

In place of the tube an iron core, A (see diagram), is substituted. The conductor is placed across the outer circumference parallel with the axis of rotation and returns through holes or channels, B, in the armature core, and is given many turns. An e. m. f. would thus be raised equal to the effective e. m. f. of one turn multiplied by the number of turns.



UNIPOLAR DYNAMO.

By calculation the e. m. f. of one turn should

$$= (\text{total lines} - \text{leakage} \times \text{velocity} \times 10^8).$$

$$= (\text{total lines} \times \text{velocity} \times 10^8)$$

After much experimentation and careful checking for errors it is found that this arrangement does not produce the slightest e. m. f. Wherein it fails does not appear where the present accepted theory of "cutting lines of force" is consulted. Therefore the conclusion appears unavoidable that the theory of "cutting lines of force" is in some manner at fault, we believe, is absolutely erroneous. By applying the law of "induction" in this case the problem is solved readily. No necessity for this experiment shows when this law is consulted.

It is stated by all authors I have read on the subject that "the magnetic field is structureless," and the assumption always follows "that it has lines of force," and hence, I take it, has structure. Does not a contradiction appear here and possibly with it a "root of evil" out of which has grown a convenient or easy-going theory that has worked the art incalculable injury?

ROENTGEN RAYS

AN EXPERIMENT SHOWING THE DEFLECTION OF CATHODE RAYS BY A MAGNETIC FIELD.[1]

BY J. A. FLEMING, F. R. S.

AN interesting experiment, showing the effect of a magnetic field upon cathode rays, was lately tried in my laboratory. It is so simple that nothing would surprise me less than to learn that many people had noticed the same thing before, although I cannot recall to mind having seen it anywhere mentioned in print.

Happening to have one of the well-known pear-shaped Crookes' vacuum tubes for showing the shadow of an aluminum cross fixed in the tube on the phosphorescent end wall when an induction coil discharge is passed through the high vacuum, I asked Mr. Morris to arrange it in front of an electromagnet, that I might see produced the effect described by Mr. Campbell Swinton lately, whereby a magnet pole placed at the end of the tube destroys in great part the green phosphorescence of the glass, and gathers the discharge into the axial line of the tube. It was then noticed by us that another curious change took place at the same time, in the form of the shadow of the metal cross; and Mr. Morris and Mr. Clinton who were experimenting with it, finally were led to try a coil traversed by current, placed round the tube as shown in Fig. 1, as a substitute for the magnet.

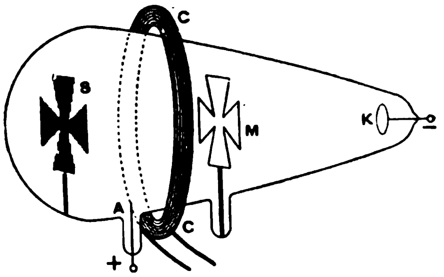


FIG. 1.—Crookes' Vacuum Tube.

K = Cathode. M = Metal Cross. A = Anode. C = Magnetising Coil. S = Fluorescence Shadow of the Cross. The diagram shows the normal condition when no current is flowing through the coil C, but when the discharge is passing through the tube.

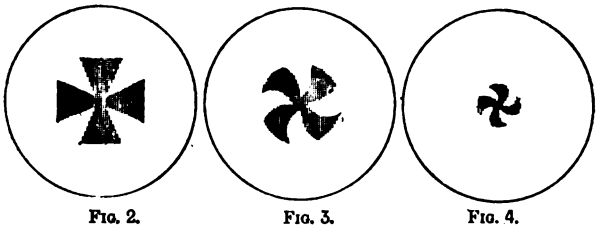

FIG. 2. FIG. 3. FIG. 4.

End-on view of the vacuum tube in Fig. 1, showing the appearance of the fluorescence shadow on the glass wall as the current in the coil C is gradually increased. Fig. 2.—No current in coil C. Figs. 3 and 4.—Gradually increased current.

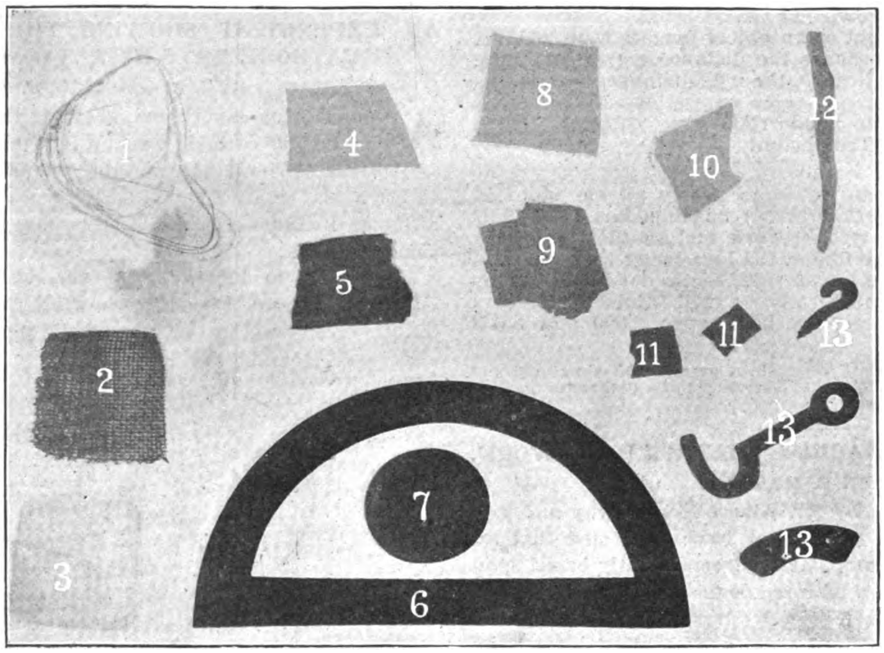
---

[1] Lond. Electrician.

The following striking effects were then noticed. When the coil embraced that part of the vacuum tube beween the metal cross and the end wall on which the shadow is formed, and when no current traversed the coil, the shadow of the cross was a dead black shadow on an apple-green phosphorescent ground, and was strictly the shadow of the cross defined by the cathode rays as in Fig. 2. When the embracing coil had a current passed through it the shadow rotated clockwise or the reverse according to the direction of the coil current, and the arms of the shadow were a little distorted or twisted round, so as to resemble Fig. 3, the leading edge of the shadow being rather sharper than the trailing edge. Moreover, the shadow was altogether smaller than in the first case. As the current through the coil was increased the shadow cross twisted itself more round, and got still smaller, as in Fig. 4; and finally as the coil current was still more increased the cross shadow was further rotated and diminished until it vanished. At the same time the phosphorescent area on the end wall contracted, but as long as there was the smallest patch of green, a tiny little cross shadow could be seen in it. At this stage the coil current was increased still more, and a new and larger cross shadow made its appearance. This shadow was not so well defined, and the background less uniformly green; but it too, as the coil current was still more augmented, screwed itself round very slightly. This second shadow had arms more sickle shaped than the previous one.

If the magnetizing coil, instead of being placed to embrace the tube between the metal cross and the end wall farthest from the cathode, was placed over the portion in between the cathode and the metal cross, then the shadow went through the diminishing process, but not through the rotating and distorting phases, as the coil current was gradually increased, step by step. In this case also there is a second stage in which a second and very much larger cross makes its appearance, which in turn contracts in size.

Any one possessing a vacuum tube of this kind, and a coil of a hundred turns or so, through which 10 or 12 amperes can be passed, can easily repeat this curious experiment. It is obviously due to the effect of the magnetic field upon the direction of the cathode rays on discharge. It is not difficult to see why. in the first case, the cross shadow rotates and diminishes; but the appearance of the second fainter and larger cross shadow seems to indicate that the effective radiant point of the cathode rays is moved nearer to the metal cross after a certain intensity of field is reached. As I hope to be able to examine the effect with vacuum tubes of other forms, I forbear to enter on any speculations at present as to the precise nature of the actions going on under these conditions. I merely mention the matter here that others may repeat the experiment, if it should prove not to be generally known at present.



PROF. MCKAY'S MAGNETOGRAPHS.

(X-Ray Phenomena Attributed to Electro-Magnetic Radiation.)

PROF. McKAY'S MAGNETOGRAPHS.

In acknowledging the receipt of a copy of the book entitled "X-Rays and the Phenomena of Anode and Cathode," by Edward P. Thompson and Prof. W. A. Anthony, Lord Kelvin states his belief that hitherto nothing in the way of diffraction has been discovered for the Röntgen rays, and doubts very much the genuineness of McKay's magnetographs described in the book. No other experimenter, says Lord Kelvin, has given any confirmation of these experiments.

As the matter here referred to seems to be well worthy of further investigation, we reproduce from the work above referred to the part referring to Prof. McKay's experiments:

"Although this experiment does not belong to that class connected with discharge tubes, yet the phenomenon has a theoretical interest in connection with X-rays. He obtained a photograph of different objects in the dark by means of radiations from the poles of an electro-magnet after two hours' exposure, but it need not have been so long, as he obtained clear images in five minutes in one experiment with frequent variations of current by means of a rheostat, and by approach and recession of the armature.

"The elements involved in the experiment were arranged in the following order: First, a large inverted magnet for supporting 100 lbs., the poles hanging downward. Next in order was a wooden board pressing flatwise against the ends of the poles of the magnet. Next the objects and the sensitive plates backed thereby and all enclosed in a completely opaque wrapping extending over the sides, face, back, etc., of these two elements. Next in order was an armature about as heavy as the magnet would support. The cut herein (see illustration) represents the photograph that was produced of the different objects named.

"By reading Prof. McKay's very detailed description in the 'Scientific American," April 18, 1896, p. 249, the reader may feel certain that the photograph was not due to light for he tried the experiments in different ways and with various precautions. In a course of experiments carried on by student Austin, about Feb. 15, 1896, in the Dartmouth laboratory, a sciagraph of what appeared to be the lines of force was obtained by means of X-rays, but upon repeating the experiment the result was negative. See "Elec. Engineer," March 11, '96, p. 257. Article by E. B. Frost."

The numbers on the accompanying engraving designate the following objects: 1. Platinum wire. 2. Copper gauze. 3. Iron gauze. 4. Tinfoil. 5. Gold foil. 6. Brass protractor. 7. Silver coin. 8. Platinum foil. 9. Brass. 10. Lead foil. 11. Aluminum. 12. Magnesium ribbon. 13. Copper objects.

BECQUEREL RAYS.

FOLLOWING out the experiment of Becquerel that certain uranium salts, after exposure to sunlight, emit radiations which, like Röntgen rays, are able to affect photographic plates with opaque material intervening, Prof. McKissick, of Auburn, Ala., has recently carried out a series of experiments, which led him to the belief that the Becquerel ray is the connecting link between the ordinary light and the Röntgen ray.

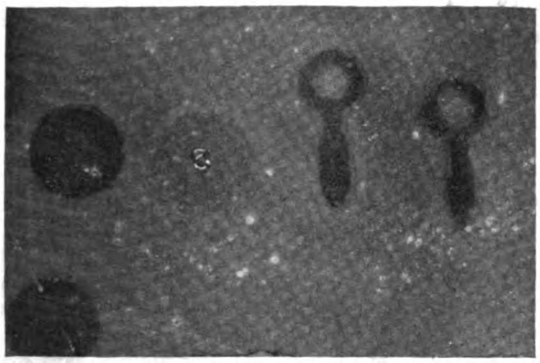


FIG. 1.

Prof. McKissick investigated the action of all the known phosphorescent and fluorescent compounds available and found that lithium chloride (in solution), barium sulphide, calcium sulphate, quinine chloride, quinine sulphate, calcium nitrate, chalk, glucose, sugar, sodium tungstate, sterein, uranium acetate, and ammonium-phospho-molybdate, give active photographic radiations after exposure to sunlight. To take the pictures, the articles were placed in contact with the sensitive plate, and the substance, after exposure to sunlight for two hours, sprinkled over the plate holder. The whole was then enveloped in a dark cloth, so as to prevent the action of any external light on the plate. The plates used were "slow" (sensitometer No. 16). Ordinary developer was used and in some of the experiments the development required an exceedingly long time.

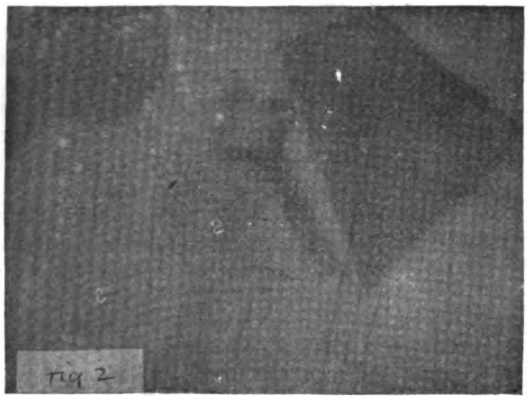

FIG. 2

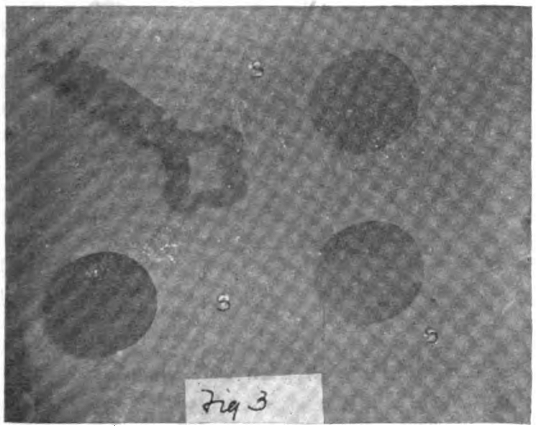

FIG. 3.

Figs. 1 and 2 are photographs reproduced of different articles taken with uranium nitrate, Fig. 1 being two keys and two copper cents, and Fig. 2 a piece of glass, a key and two coins (a copper cent and a quarter). A very peculiar property of this radiation is that generally more than one image of an object is produced on the plate although the object is in contact with the plate) as may be seen by closely inspecting the photographs reproduced. For simplicity we may designate the sharper and more pronounced image the primary and the less distinct ones the secondary, being marked with the letter "S" in the center.

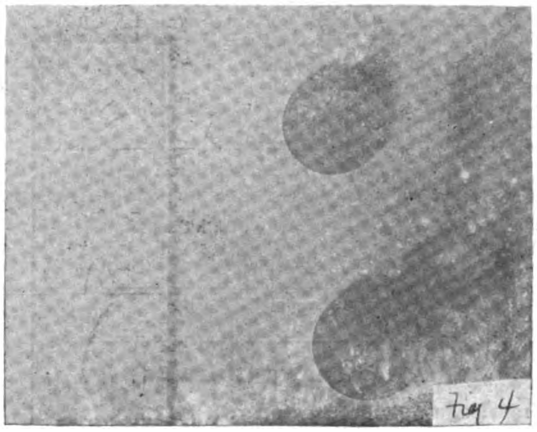

FIG. 4.

Of all the substances tried Prof. McKissick found that white granulated sugar gave the best results. Fig. 3 is a photograph of a key, three copper cents and an irregular piece of glass (secondary images marked as usual with "S"). Fig. 4 is a photograph of two coins, a key and a piece of glass, sugar being used but acting through a piece of wood 2½ inches in thickness. In one negative Prof. McKissick noticed as many as five images of one object and sometimes on the same negative there would be two images of one object and only one of another object only two inches away.

It was suggested by Prof. B. B. Ross that inasmuch as quite a number of fluorescent and phosphorescent substances possess high molecular weights, other substances of high molecular weights, although not known to be either fluorescent or phosphorescent, might give off these rays.

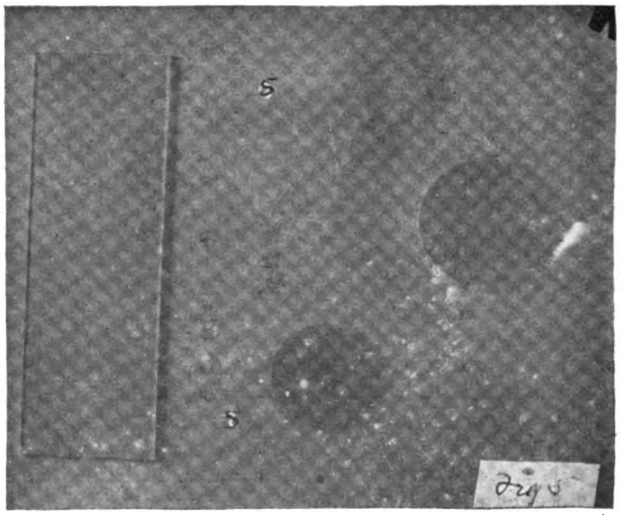

FIG. 5.

With this idea sterein and ammoniumphospho-molybdate were tried, and both were found to give off Becquerel rays, the first, sterein, very slightly, the second, ammoniumphospho-molybdate, giving a fairly clear and sharp negative, as will be seen by inspecting Fig. 5, the articles being a piece of glass, two coins and a key. The secondary images are marked as usual with the letter "S," that of the key being rotated through an angle of about 45 degrees. Uranium nitrate sprinkled on top of the plate holder and then exposed for 18 hours to the sun gave only a faint negative.

VOL. XXIII. NEW YORK, JANUARY 20, 1897. No. 455.

WHAT WILL SHE DO WITH IT?

THE marriage union of Niagara with Buffalo was celebrated last week, three months after the consummation. But in reality, the festivities were precipitate rather than tardy, for had matters been left to the ordinary course of physical events, the arrival of Niagara at Buffalo would be a convivial opportunity for our descendants 60,000 years hence. A little computation will show that at its crab-like travel of two feet a year, Niagara would not have eaten its way backward through shale and limestone to the water front of Buffalo in any shorter period. Thus do the modern inventor and the genius of electricity anticipate the flight of time. It is curious that the same year which learned the discovery of the supersubtle X-ray should have witnessed, at the other end of electricity's scale, the harnessing and distribution of Niagara's illimitable energy. The year 1896 was memorable, and when we have fairly emerged from its wrecks and disasters we shall recognize its many lasting benefits. In America we established anew our national honor; we vindicated our right to lordship in this Western world; by a treaty of arbitration we federated willing England into the American Union of mutually pacific States; and chief among the triumphs of peace, we subdued nature at Niagara that we might give larger liberty to every American workman.

How wild and fantastic it all seemed a few short years ago, this Niagara project! The tightrope dancer balancing himself painfully above the roaring, awful abyss of the Falls had not more nerve and courage than the men whose money and brain have created a new power center for the world, to whose balance industries must now poise themselves as do peoples in international politics. A region of 22 miles radius, with Buffalo as its center of attraction and Niagara as its source of power, has within six years been made the potential heart of manufactures in the United States. The organizers of the great enterprise have gone to Niagara and after a brief but decisive struggle are able to turn around and say to all who need cheap power and are willing to come to the Buffalo region for it: "We have met the great Cataract—and she is yours." The Delilah who has tamed this Samson of water powers can invite us all to witness and enjoy the spectacle, without fear of harm or future danger for anyone, and in the knowledge that Samson is the better man for having his hair cut in a civilized fashion. Of a truth, the salad, festive days of Niagara are over, and a career of strenuous effort has begun. While the older methods of utilization disfigured her, this modern plan is unobstrusive in its continuation or protection of her charms. As a matter of fact, the power of Niagara has more beauty than her beauty has power, for hitherto the human intellect and imagination have avoided her as a background for their creations. Ideas vary as to desirable qualities. Dean Stanley admired Jenny Lind immensely, but said she would have been simply delightful if she had not sung. The deep note of Niagara is now mitigated into the cheerful hum of toil; the present picturesque aspect of the Falls is preserved and conserved; Buffalo has attained the long-felt wish of seeing Niagara at play and work in her back yard—and the Power company is already selling 25,000 horse-power for somewhere around half a million dollars a year. Is not this a happy result in common for aesthete, financier, inventor and engineer? And how rarely it happens!

To Buffalo we would simply address the friendly admonition of liberality. It has cost that city absolutely nothing to have the power of Niagara brought to her doors. Freely she has received, freely let her give. Now is the time for her to encourage the Niagara Power Company to spend more money in her behalf. The whole question now that Buffalo has got the power is: What will she do with it? If she reward largeness of enterprise with corresponding largeness of welcome, there is no doubt as to her future. No greater mistake can be made than for people or city to stand suspiciously aloof when great progressive enterprises touching their welfare are afoot. "We don't own it," growled a passenger angrily when disturbed in his sleep and told that his services were needed at the pumps because the steamer was going down. Such narrowness of mind is always suicidal, and nothing that represents thrift, property and courage is ever injuriously affected without the community feeling it far more than the few individuals. The dignified and manly plea of Mr. Stetson at the banquet, for honorable treatment of his company which right through the hard times has spent its money with Niagara profusion, must find a cordial response from every public-spirited Buffalonian.

In a sense, the Niagara-Buffalo banquet was a distinct tribute to the modern electrical inventor, and as all these sentiments crystallize around personalities, the honors were paid very appropriately to Mr. Tesla, who when everybody else felt dubious, said the thing must be, taught us how to do it—and it is. That such men as Brush, Thomson, Sprague and other electricians were there to share these honors, was eminently fitting and fortunate, for while each great worker does something, no one genius can do it all. What such men need from us is encouragement, sympathy, applause. The hanging of Frank Sprague in effigy at Louisville because his trolley freed the mule, simply shows that the way of the inventor, like that of other transgressors, is generally hard. The extent of his innovation marks the degree of his impropriety, and society has usually seen to it in days gone by that the punishment should fit the crime. Even now, when the inventor is becoming more and more a person to magnify, it is all struggle for him; frequent defeat, rare victory; headlong torrents and sheer cliffs to breast and lift above; and once in a while, like Capt. Webb, the brave swimmer is carried under, a victim to his own intrepidity. We cannot follow these men in all their efforts and intuitions, but we can feel for them as fellows, sorrow when achievement lingers, rejoice when victory greets some golden morning, and, as on occasions like this Niagara banquet, drink royal toasts of amity and admiration in their honor.

THE COST OF MUNICIPAL ELECTRIC LIGHTING.

NEW ENGLAND thrift is proverbial and the high order of economy which has been reached in its famous mills and manufactories is reflected to a large degree in the administration of municipal affairs in that section. New Englanders generally look before they leap, and a striking example of the carefulness with which municipal expenditures are undertaken in that section is shown in the results of an investigation set on foot by the municipal authorities of Brookline, Mass., with a view to the installation of a municipal arc light plant. We have before us the report made by Mr. Nathan Matthews, Jr., to the Selectmen of Brookline, and we commend this document to all citizens as well as municipal authorities in general, as one of the best on the subject which has yet come under our notice. It has been the general practice for municipal authorities about to install electric light plants to send a junketing committee abroad to visit plants and to report upon their impressions. These reports as a rule contain statements and statistics which rarely receive thorough investigation as to their reliability, the cost of municipal lighting in the majority of cases being given as merely equivalent to the ordinary running expenses of the stations without taking into account other essential items. In marked contrast to this is the plan adopted by the Selectmen of Brookline. Instead of a junketing committee they employed two independent competent engineers; one of these, Mr. Wm. Jackson, city engineer of the city of Boston, and Messrs. Stone and Webster, electrical engineers, also of Boston. Each of these made independent reports and submitted answers to questions put to them involving estimates of the cost to construct and operate electric light plants of a capacity varying from 250 to 750 lights. The annual cost of operation of one arc lamp per year, as given by the two experts, runs from $106.65 for the largest plant, to $149.83 for a plant of 500 lights run for 250 only. As the margin of 100 per cent. in the capacity of the power station in the last mentioned case is more than would seem to be necessary, Mr. Matthews takes as more nearly meeting the actual conditions another figure submitted, namely, $123.04, which represents the cost of operation for running 375 lights with a plant having a total capacity of 500. The figure $106.65 is that given for 500 lights operating from a station with a total capacity of 750.

As Mr. Matthews very truly points out, these figures are on the one hand considerably less than the cost of manufacture as claimed by the private companies interested in the business, and on the other hand higher than the cost of lights operated on public account as set forth by some of the advocates of municipal ownership. Mr. Matthews believes that the fact that these prices are lower than private companies commonly claim to be the actual cost of manufacture and distribution is explained, among other things, by the fact that many of the companies now engaged in electric light business are conducting their business with old-fashioned or obsolete machinery, which in the aggregate has cost considerably more than a fresh modern plant would and is more expensive to operate. But he also shows that these prices on the other hand are higher than those frequently set up by theoretical advocates of municipal ownership. This is due first to the very general omission by the latter of adequate allowances (when any are made at all) for interest, depreciation, insurance and taxes; and secondly, to the fact that many, in fact, nearly all, of the official accounts published by municipal corporations of the operation of their electric light plants fail to include among the actual expenses of operation many items which should properly be charged thereto, such as general office or administrative expenses, rent, salaries, etc. Thus, in figuring the actual cost of operation for Brookline there has been included interest on the total cost of the plant at the rate of 4 per cent., and not, as is commonly done in such calculation, on the amount of bonds outstanding, if any, issued for the purpose of procuring the plant. That interest should in this matter be reckoned into the calculation is disputed by some advocates of municipal ownership, but Mr. Matthews points out that the problem is practically the same as that which arises in the domestic economy of the individual citizen when calculating the relative advantage of hiring a house or buying one to live in. If in this calculation of the cost of living in a purchased house, he would leave out interest on the cost of the house, the result would obviously be fallacious; for if he had not invested his money in the purchase of the house he would have it to invest in interest- or income-producing property. It seems strange that such plain facts should require to be so explicitly stated, but that they are necessary is evident from what we have seen in municipal plant operations in the past.

Taking the probable figure of the cost of electric light at Brookline as given by Mr. Matthews as $123.04 per lamp per annum, it will be seen that this comes very close to the prices charged by most private companies throughout the country, where the amount of lighting is in fairly concentrated districts. In New York, for example, the rate of 40 cents per night makes the cost per lamp $146, or only $23 more than that given for Brookline with the highest type of modern apparatus. When we consider that, as truly pointed out, much of the apparatus employed in the present stations in New York City is antiquated and that the New York companies are burdened with rentals of underground conduits and other incidental expenses which the Brookline plant would not be subject to, we leave it to any fair-minded citizen to judge of how much profit there can be in arc lighting at 40 cents per night. We wish that every municipality before entering into the subject would as thoroughly investigate it as have the citizens of Brookline. If such had been the case we would probably not see so many municipal plants at the present time struggling along under a loss to the citizens and in many cases unable to compete with private companies.

A year or two ago fire insurance companies were howling calamity, declaring frightful losses in their business and loading all the blame on poor electricity. Never a bad or mysterious fire happened, but they at once surmised the cause to be "a defective electric wire." Last year one company made a clear profit of 86 per cent., another of 61, another of 55, another of 48 and another of 29. Suppose they now give a little tardy credit to electricity which is more used to-day than ever.

EVEN the elect are sometimes deceived, but Dr. Richard Hodgson,president of the Boston Society of Psychical Research, intimates that Dr. Oliver Lodge was more than fooled by the Italian medium, Eusapia Paladino, who has lately been exposed. It would appear that Dr. Lodge wrote a paper in her behalf, read it before the British Society of Psychical Research and would have published it in the transactions but for the intervention of a merciful Providence. We have not seen the volume, but if Dr. Hodgson may be believed, the title is in the table of contents, though the paper by the great physicist is missing.

THE Pacific cable is still in the air—instead of in the water—and the New York "Sun" thinks that as Congress is handy, an American Company may still do the work and own the cable. It is not easy to find out just "where one is at" in this matter, but it will be strange if an English cable, after all, is not the first to cross the Pacific. The English are just as able at cable laying as they are at ship building, and one more link in their cable system is quite in the natural order of things. But our politico-financial interests in the East require that the United States should at least have a say in the matter, and not stop short at mere "say."

IT is a pity that the word "Electric" continues to be so abused by misapplication. The puzzled electrical journalist can never be sure now whether a new enterprise is electrical or not, judging merely from its name. An electric grain elevator company has just been formed, but the managers now say that no reference is made to the use of electric power. Last week an "electric" laundry company was formed at Rochester, N. Y., but it is quite possible it will employ "electric" soap and not Mr. James I. Ayer's ingenious flatirons, using the juice of the dynamo.

EDDY POWER PLANT IN THE CONSOLIDATED DENTAL CO.'S FACTORY.

THE processes of dental manufacture are numerous, intricate and often delicate, requiring that the power applied to the machinery shall be smooth and uniform. Competition in the industry of late years has been no less rife than in other lines of trade, so that every possible economy has had to be inquired into with a view to its adoption. These considerations readily explain the decision of Mr. G. J. Bultman, vice-president of the Consolidated Dental Manufacturing Company, when equipping their large new factory at One Hundred and Sixty-second street and Brook avenue, New York City, to equip with electric power entirely. The plant is illustrated herewith, and must be regarded as a model of its character and class.

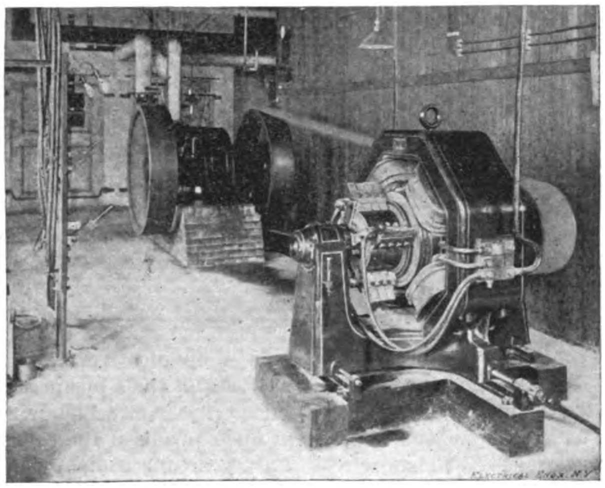

FIG. 1.—EDDY GENERATOR DRIVEN BY ARMINGTON & SIMS ENGINE, CONSOLIDATED DENTAL FACTORY.

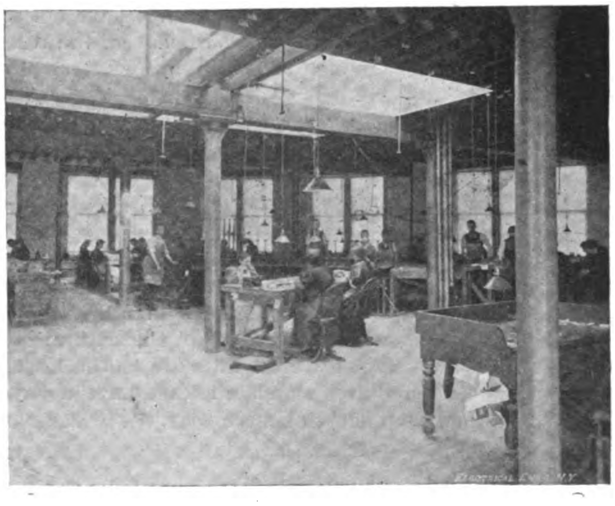

FIG. 2.—TRIMMING ROOM, USING ELECTRIC HEAT IN ITS WORK.

The electrical equipment referred to and shown in the engravings was furnished by H. B. Coho & Co., of 203 Broadway, New York. It comprises a 60 kilowatt Eddy generator driven by a 13 by 12 Armington & Sims engine operating no fewer than ten Eddy motors, ranging from 2 horse-power up to 10 horse-power. The dynamo supplies current for light, power and heat, and all the circuits are controlled from the switchboard in the engine room, each motor being protected by an automatic release box and circuit breaker, as required by the Fire Department. The plant is so designed that each room has its own independent motor, and in some places where the work on one floor is unlike or separated, two motors are placed in the same room. For example, the polishing rooms require considerable power at certain periods of the day, and these have an independent 5 horse-power Eddy motor. The main idea running all through the work is that when no power is required, none shall be furnished and thus none wasted, so that the item of power in the operating expenses is kept down to the lowest notch. Fig. 1 shows the dynamo room. Fig. 2 is the trimming room; Fig. 3 the machine shop, and Fig. 4 illustrates a 5 horse-power motor on a wall bracket, used for the cutting and rolling work.

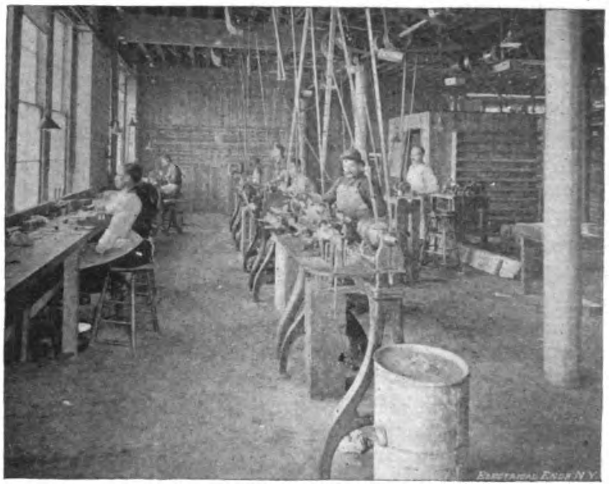

FIG. 3.—MACHINE SHOP OPERATED BY ELECTRIC MOTOR.

It will be seen that a large part of the capacity of the generator is taken up by the motors, but for night work, etc., no fewer than 250 lights of 16 candle-power have also been installed. As to the motors, it may be noted that they have been very carefully installed, being all placed out of the way of travel and run of shop work material and protected from dust or dirt. In addition to the current supplied for light and power, about 80 amperes is taken by some special electric heating appliances, used in porcelain teeth making processes where very regular and steady heat is required, susceptible of fine gradation and regulation. These heaters or muffles were made by the American Electric Heating Corporation of Boston. It should be added that the Consolidated Dental Company not only make teeth but fine steel dental instruments, etc., and are a busy concern whose reputation has been made by the quality of their goods. This general resort to electricity by Mr. Bultman and his associates in the company is, therefore, at

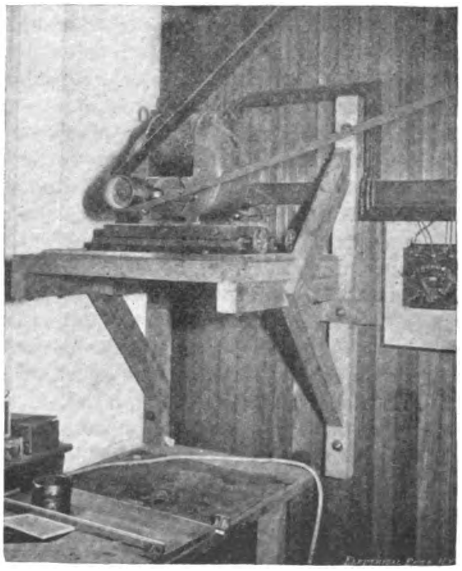

FIG. 4.—5 H.-P. EDDY BRACKET MOTOR DRIVING THE CUTTING AND ROLLING MACHINERY.

once encouraging and significant, while the plant itself reflects much credit on the contractors and the manufacturers of the apparatus.

THE BUFFALO-NIAGARA POWER CELEBRATION.

A Memorable Banquet in Buffalo, Jan. 12, 1897.

No sooner had the energy of Niagara been actually delivered in Buffalo, by means of electricity, and applied to the operation of the street cars, than it was felt that such an occasion ought to be fitly celebrated. Just in what way the great event should be signalized, it was, however, difficult to decide. Many people in the city of Buffalo wanted a big electric carnival and will probably have it sooner or later, but time was slipping by, and the occasion was losing the impressiveness that is always given by a public function. In this state of affairs, the Cataract Power and Conduit Company, which is the corporation handling the power in the city of Buffalo, took the matter in charge for itself, and determined to give a banquet that by its character should do justice to one of the grandest achievements of the century; and the organization of this was judiciously entrusted to the two well-known Buffalonians, directors in the company, George Urban, Jr., and C. R. Huntley. The date of January 12 was fixed and the beautiful new Ellicott Club was selected for the purpose.

Many of the guests arrived early on Tuesday, the 12th, and spent the day at the Falls, viewing the works, a party being made up under the care of the Niagara Power people; and in the evening some 400 mustered at the club. It is not necessary that we should give the complete list of the invited, but the subjoined names of those present in behalf of the various branches of electricity will afford an idea of the gathering and of its representative nature: E. G. Acheson, C. F. Brush, W. A. Brackenridge, C. A. Coffin, W. G. Case, W. L. R. Emmet, T. H. Feary, H. A. Foster, S. D. Greene, F. A. Gilbert, F. W. Hawley, S. M. Hamill, J. S. Humbird, R. Hammond, G. B. Hayes, E. J. Hall, S. M. Hamill, C. R. Huntley, W. J. Johnston, W. H. Lawrence, H. M. Littell, F. D. Locke, T. C. Martin, B. F. Miles, F. Nicholls, D. O'Day, J. P. Ord, C. W. Price, D. B. Parker, E. W. Rice, Jr., C. P. Steinmetz, F. J. Sprague, W. W. Sloan, H. G. Stott, Elmer E. Sperry, Elihu Thomson, Nikola Tesla, C. A. Terry, J. G. White, H. M. Watson, P. M. Lincoln, L. B. Stillwell, B. Van Horn, P. A. Porter, N. J. Porter.

The company itself was represented by Directors D. O. Mills, F. L. Stetson, E. D. Adams, E. A. Wickes, D. O'Day and Messrs. Urban and Huntley. The distinguished guests representing politics, finance, engineering, journalism, etc., were numerous. The menu was handsomely printed in the shape of a little book about a quarter of an inch thick, bound in thick aluminum covers, the metal being made by the power of Niagara in the works of the Pittsburg Reduction Co., at the Falls.

The speakers and officers occupied a raised table across one end of the room. Mr. Urban introduced MR. STETSON, who said:

Mr. Mayor and Gentlemen.—To these festivities, which you have honored by your presence, the Cataract Power and Conduit Company of your city of Buffalo has requested me to bid you welcome and to make a brief statement concerning the part taken by the company in the introduction of Niagara power into this Queen City of the Lakes. Shortly after enterprising citizens of Buffalo had proposed to give $100,000 as a prize for the device of a practicable method of using the Niagara power in Buffalo, there was organized, in 1886, exclusively by citizens of Niagara Falls, the company which since 1889, has been known as the "Niagara Falls Power Company," or the "Tunnel Company," and which in July, 1889, entered into a contract for the construction of its works at Niagara.

This contract was made with the Cataract Constuction Company, composed then exclusively, and now principally, of citizens of New York. In the course of the six years since this original contract the Cataract Construction Company, without thus far receiving one penny of profit or dividends or interest, has provided for expenditures exceeding $6,000,000 in money, exclusive of interest, thereby acquiring substantially all of the stock of the Niagara Falls Power Company.

Incidentally, the power company has promoted the formation and the business of the Niagara Falls Water Works Company, and of the Niagara Falls Junction Railway Company, and also of the Niagara Development Company, intended for the provision and establishment of a satisfactory residential district for employés connected with the various industries established and to be established around the power house at Niagara Falls.

Naturally, the interest and object of first importance to the Niagara Falls Power Company would be the establishment and development of its installation at Niagara; but, notwithstanding the fact that the employment of its power at Niagara Falls would be much more profitable than its transmission for use elsewhere, it was and is impossible for the company not to recognize the ultimate benefits both to itself and to this community of providing for the use of its power in this great, growing and enterprising city of Buffalo.

Accordingly, in October, 1894, the Niagara Falls Power Company made application to the local authorities of Buffalo for the right to introduce Niagara power into the city and to make use of the city's streets for its transmission and distribution. That this application was not granted in precipitate haste or without due consideration is indicated by the date of the franchise, which was approved by His Honor the Mayor on December 16, 1895, 14 months after the original application.

As granted, the franchise was free from a number of conditions originally proposed, which to the Power company seemed unduly onerous, in view of the fact that now, at its own risk and without asking compensation, it was offering to bring about the result for which a few years previously public sentiment in this city had proposed to give a prize of $100,000. In its final form, the franchise was intended to be fair to both parties, and no reasonable complaint of its conditions can be made by either, although some modifications may yet become necessary, as to one of which presently I shall have something more to say.

Naturally enough, the Niagara Falls Power Company, in the introduction and distribution of its power in this city, desired local support and assistance. Accordingly, several prominent and public-spirited citizens of Buffalo were induced to organize the corporation now known as the "Cataract Power and Conduit Company," to which, with the consent of the common council, under the 12th article of the franchise, the Niagara Falls Power Company has assigned its grant, and this new Cataract Power and Conduit Company, directed principally by citizens of Buffalo, has undertaken the duty of distributing, within the city limits, the power brought to the boundary by the Niagara Falls Power Company.

The franchise of December 2, 1895, required the Power company, within 90 days after acceptance of its provisions, to present and to file with the Board of Public Works, for its approval and for the approval of the common council, plans and specifications for its work, and with this condition the power company strictly complied. It was further required that on or before June 1, 1897, the company should be prepared to supply 10,000 horse-power to consumers within the city, and with this condition the company has so far complied that upon the first day of December, 1896 (six months before the specified date), it introduced into the city of Buffalo 1,000 horse-power, which from that time on has been satisfactorily employed by the enterprising, intelligent and public-spirited directors of the Buffalo Street Railway Company, whose president and whose manager we are glad to see here to-night, and to whose justifiable confidence in the sufficiency and continuity of Niagara power the city of Buffalo is indebted for this early introduction.

It is, however, proper to observe that a reasonable postponement of the date before which the remaining 9,000 horse-power shall be required to be ready for use in this city will be necessary. It is entirely credible that, like the business men of every other city of the United States, the citizens of Buffalo found the spring and summer of 1896 exceptionally unfavorable for the promotion or prosecution of business enterprises involving novel elements, or calling for the expenditure of considerable sums of money. But whether or not this were so in Buffalo, it is true that during the year 1896, and prior to November 4, few corporations undertook or accomplished in the way of new construction more than did the Niagara Falls Power Company and the Cataract Power and Conduit Company in the installation of the line, for generating and transmitting the Niagara power now in use in the city of Buffalo. Naturally enough, all desired that such installation should be established with such care as to avoid, so far as possible, the chance of failure and disappointment in operation, and, therefore, it was deemed best, not to provide all the new machinery required for 10,000 horse-power until after the actual test of the transmission of the 1,000 horse-power, for the delivery of which upon December 1, Mr. Littell contracted in August, 1896.

The actual test having been made with results wholly satisfactory, the Niagara Falls Power Company now has concluded its contracts for the immediate generation of not merely 10,000 but of 25,000 additional electrical horse-power, of which as much as required will immediately thereupon be available for transmission to Buffalo. The contracts for this purpose have been actually assented to, and the money therefor has been actually provided.

The contract for an extension of the wheel pit sufficient to receive all the machinery for 50,000 electrical horse-power was made in 1896, and work thereunder has been and now is proceeding with the stipulation for its completion during the month of May, 1897.

It had been supposed that the turbine wheels and the generators also could be furnished before that date, but the contractors are now unable to promise such completion, and, accordingly, there must be an extension of the period within which the delivery of the remainder of the first 10,000 horse-power to this city shall be required, so as to enable the contractors progressively to furnish the five turbines and the five dynamos for which, as I have already said, the contracts have already been made and the money provided. We have no doubt that the public spirit of Buffalo, which originally perceived the city's peculiar and great advantage in its proximity to Niagara power, will now recognize the appropriateness of the request for such an extension, and by prompt acquiescence will encourage and stimulate the extended provision of Niagara power for use in this city.

It is a pleasure to be permitted to welcome here one of the most distinguished sons of Buffalo, the Comptroller of the State of New York. For it is not to be forgotten that through the wise and liberal disposition of the executives and legislatures of the State, the development of the Niagara power has been made possible within its boundaries.

Rights in respect of the Niagara power, upon the Canadian side, have been granted by the Province of Ontario upon terms which, though specially advantageous to the Province, are in some particulars more favorable to the company than are those conceded by the State of New York. For while it is true that the Canadian Niagara Power Company is under agreement to pay to the Province of Ontario an annual rental of $25,000, this rental secures to that company the right to place its works inconspicuously within the limits of the public reservation, and so near to the very Falls themselves as to avoid more than 6,000 feet of tunnel, which upon the New York side had to be constructed at a cost of nearly $600,000, to bring the power house of the company above the limits of the State Reservation. It requires but a moment's calculation to show that the interest upon the additional construction required in the State of New York is more than equal to the entire rental paid to the Province Ontario, and that thus I am justified in saying that in some particulars the Canadian grant is more favorable to the company than that in the State of New York, although there results to the provincial treasury a pecuniary profit which similarly might have resulted to the State of New York, except for the requirements as to the position of the company's works.

From beginning to end the Power company has recognized the glory of Niagara Falls as the first object of great natural beauty and power upon the face of the earth; and therefore, while conscious that its works on the American side might have been constructed as near to the falls as will be those of the Canadian Niagara Company, without conspicuous or undesirable interference with the aspect or the volume of the mighty river or its cataract, the officers of the Power company have cheerfully acquiesced in a requirement which has resulted in the erection of its beautiful buildings and works at a point more than a mile above the falls and utterly beyond observation therefrom.

The result thus accomplished, with every promise of immediate and satisfactory extension, for this, the second city of the Empire State, may also in a future not far distant be made available under conditions of course less favorable than those prevailing, but still upon terms advantageous to other cities in our State, and also for use as required upon the canals of the State. For, though the Niagara Falls Power Company has no relation whatever to any grant upon the canals, excepting a license for its very slight use of canal lands in Niagara and Erie counties, it cannot fail to recognize the energy and enterprise of other organizations which may become users of Niagara power for the relief of the important interests, which either in the ownership or the navigation of canal boats or of their cargoes, contribute largely to the commercial importance of the Empire State and of its cities upon the line of the canal and of the Hudson River.

Under these conditions the promoters of the use of the Niagara Falls power and its electrical transmission feel that not improperly they may presume themselves in some degree to be working for the public benefit, as well as for legitimate personal profit.

Such, too, is the position which the Cataract Power and Conduit Company desires to occupy with reference to the city of Buffalo. This company hopes and believes that an extensive and continuing use of Niagara power in this city not only will result to the material and financial advantage of those now producing nearly 40,000 horse-power from steam engines, at a cost believed to be at least twice that of Niagara power, but also will relieve this beautiful guardian of Lake Erie and the Niagara River from the veil of smoke so often obscuring her charming aspect. While it is true that in this particular Buffalo already is more fortunate than some of her Western neighbors, still it is to be desired that, availing of the opportunity which she alone possesses, she may entirely cast off this pall.

Extended investigation by this company into the cost of steam power from coal or from oil or from natural gas in the various cities of the world, has convinced us all that nowhere upon this earth has any great city such an advantage as that now opening for Buffalo through this introduction of Niagara power; and in sanguine expectation of such prosperity and profit, which can result only from a service that shall be equally profitable and satisfactory to this city, the Cataract Power and Conduit Company bids welcome to the citizens of Buffalo, and to its Mayor, from whom we all now desire to hear.

MAJOR JEWETT responded with a brief and interesting speech of welcome to Buffalo. He was followed by State Comptroller J. A. Roberts, who gave some figures on the importance of New York, in response to the toast of "The Empire State." Then came what in many ways was regarded and treated as the event of the evening, the response given below to the toast of "Electricity" by MR. NIKOLA TESLA:

I have scarcely had courage enough to address an audience on a few occasions which were unavoidable, and the experience of this evening, even as disconnected of the cause of our meeting, is quite novel for me. Although on these fête occasions, of which I have retained agreeable memory, my words have met with the most generous reception, I have never deceived myself, but have known full well that my success in those instances was not due to any excellency in their rhetorical or demonstrative art. Nevertheless, my sense of duty to respond to the call with which I was honored a few days ago was strong enough to overcome my very grave apprehensions as to my ability of doing justice to the topic which is assigned to me. It is true that at times, even now as I speak, it seems to me as though my mind would be full of the subject, but I know that just as soon as I attempt expression the fugitive conceptions will vanish and I shall experience those well-known sensations of a certain abandonment, chill and silence. I am deeply earnest in my wish that I were capable to have the flame of eloquence kindled in me that I might dwell, in terms adequate to the occasion, on this wonderful science of electricity, on the marvelous progress which electrician honors have recorded and which one of the speakers justly said stamped this age as the age of electricity, and more particularly on this extraordinary event which we are commemorating this day. Unfortunately, this, my desire, must remain unfilled, but I shall hope that in my formless and incomplete statements, in a few ideas I shall mention, there may be something of interest, something befitting this unique occasion.

Gentlemen, there are in the intellectual development in recent years certain features which are especially comforting to all those who have truly at heart the advancement and welfare of mankind. First of all, the inquiry into the nature of our organs and senses by the aid of microscope and otherwise, particularly into the nature of those organs with which we commune directly with the outside world and to which knowledge is conveyed to our minds, has revealed their exact construction and mode of action, which is in strict accord with simple physical principles. Therefore, the observations we make of facts we derive by their help are real facts and observations and our knowledge is true knowledge. To illustrate, for instance, our knowledge of form is dependent upon the fact that light propagates in a straight line, whereby an image thrown upon a lens is exactly similar to the object seen.

In fact, my thoughts in these lines and directions have led me to the conclusion that all human knowledge is resting upon that simple truth, for any idea or conception, therefore knowledge, involves a visual impression or image; but if, for instance, light would not propagate in a straight line, but according to any other law we might presently invent whereby not only the image would not resemble the object, but even the images of the same object at different times and distances would not bear any resemblance, then our knowledge of form would be incomplete and defective, because then we might see a three-cornered figure, or six or twelve-cornered. You see, therefore, that the exact knowledge of our organs, of the mode of action of the mechanism, disposes altogether of a doubt as to the truth and reality of the outward impressions, and thus we bar out, forever we shall hope, that unhealthy speculation and scepticism which formerly used to take hold even of the strongest mind. Let me tell you of another comforting feature: The progress, as measured in a given time, is nowadays much more rapid; greater than it ever was before. This is in strict accord with the fundamental law of motion which commands that there shall be acceleration, or increase of momentum, of accumulation of energy under the action of a continuous force or tendency.

For what is progress if not a movement, infinitely complicated and sometimes unscrutinizable, it is true, but yet exactly determined as to the quantity and quality of movement by the conditions and laws governing it. Now, this feature is nowhere better shown than in the gradual merging of the forces, sciences and arts in the obliteration of the hard-and-fast lines of separation of borders which, only a few years ago seemed unsurpassable and which, like veritable Chinese Walls, surrounded every department of inquiry and barred progress. A sense of connectedness of the various forces and phenomena, a deeper understanding of nature is taking hold of our minds now, a sense not clear and definable as yet, but still sufficiently keen to fill us with confidence as to the greatest realization in the near future. But these features which I have mentioned and which bear upon the subject more intimately than I have said, only interest the scientific man, the thinker, the reasoner. There is another feature far more comforting, of far more universal interest, because of its bearing upon the welfare of mankind. Gentlemen, there is in all departments of human activity an influence felt which grows stronger day by day, which is asserting itself everywhere wherever human activity shows itself, an influence most fruitful and beneficial, the influence of the artist.

It was he, the artist, who abolished that narrow, pedantic school teaching which made often an aspiring student a galley slave. It was he who afforded freedom and choice of subject of study and facilitated free development. Now, there are some men who delight in the exercise of the powers of criticism who will tell you that this asymmetric development is a departure from the normal, a degeneration or degredation of the race. But these men are wrong. This is a healthy state of things, a blessing, the establishment of conditions best suited for progress. Let each of us concentrate all his energies in one single effort. Let him perceive a single truth, even though he be consumed by the sacred fire. Then millions of less gifted people will follow.

Therefore, it is not the quantity, but the quality of work which determines the magnitude of progress. It was the artist, too, gentlemen, who awakened that broad, philanthropic spirit which, even in old ages, is shown in the teachings of noble reformers and philosophers, a spirit which makes men in all stages and positions work, not as much for any material benefit or compensation, although reason may dictate this also, but for the sake of success, for the pleasure there is in achieving it and for the good they might do thereby to their fellowmen. Under this influence a type of men is now pressing forward, inspired with deep love for their study, men whose chief aim and enjoyment is the acquisition and spread of knowledge, men who look far above earthly things, whose banner is Excelsior! Gentlemen, let us honor the artist, let us thank him, let us drink his health.

Now, in all these features, in all these possibilities which I have mentioned at random, the knowledge of electricity, the expansion of the science of electricity has been a most potent factor. With these cheering prospects we do not need to look with any feeling of uncertitude or apprehension on the future. There are men who will tell you anxiously that the nations are arming; that they are arming to the teeth; that they are going to pounce upon each other at a given signal and destroy each other, like the cats of Kilkenny; that they are trying to outdo that victorious, great, wonderful German army, against which there is no resistance, for every German has the discipline in his very blood; every German is a soldier. But these men say again; look at our experience in the Venezuela difficulty with the British. Two other nations might have crushed together, but not the Anglo-Saxon; they are too far ahead. These men who tell you so are ignoring forces which are at work silently, but resistlessly, forces which say Peace.

Now, and none too soon, a cry will be echoed everywhere, let us stop these high-handed matters, these remnants of barbarism so inimical to progress; let us turn our attention to the common enemy, to the common dangers which threaten us everywhere—in the air we breathe, in the water we drink, in the food we consume. Is it not strange, is it not a shame, that we, beings of the highest stage of development, with such immense powers of thought and action, we the masters of the universe, that we cannot know whether in a swallow of food or drink we are taking in joy and life or pain and destruction? But enough of this. Let me turn again to the more pleasant and real things.

I have referred before to the certain merging of sciences, to a certain understanding of connection between the various widely-different phenomena and forces. We know through the efforts of a bold pioneer chiefly that heat, radiant heat I mean, light, magnetic and electric phenomena are very nearly alike. The chemist professes that the combinations and separations of bodies he observes in his department are due to electrical forces, and the physician or the physiologist will tell you that even life's process is electrical. Thus electrical science has gradually gained a universal meaning, and with right we may call this age the age of electricity. But I have very strong reasons, reasons which my co-workers will appreciate, to follow a precedent established by a great philosopher, and I shall not dwell on the purely scientific aspect of electricity. There is another reason to the claim which I have before stated, which is even more potent than the former, and that is the immense development in all electrical lines and the influence of this development upon other branches of science and industry.

MR. TESLA had just begun to make an interesting reference to the steam engine and the part that he hoped his oscillator might play hereafter in the integral combination of dynamo and engine, when he was informed that he must leave at once to catch his train. He therefore closed as follows:

"I am just informed, gentlemen, that in three minutes we have to leave. I congratulate you. (Laughter). What can I say, if not words which I am sure will be echoed by you all. I can only congratulate those who have co-operated in bringing about this great advance. I can congratulate the courageous pioneers who have embarked in this enterprise and carried it to success. And lastly, and this most sincerely: Buffalonians, I would say friends, let me congratulate you on the wonderful expanse of possibilities open, and let me wish that in no time distant your city will be a worthy neighbor of the great cataract which is one of the great wonders in nature.

MR. C. W. GOODYEAR then responded to the toast of "The City of Buffalo," which he spoke of as producing two presidents—Fillmore and Cleveland. Then came a string of very handsome regrets and congratulations from President-elect McKinley, Mark Hanna, "the king-maker;" T. C. Platt, Thomas Lowry, and others. Young Mr. Cramp, of the great Philadelphia shipbuilding firm, then spoke of himself briefly and very pithily as the builder of the Niagara turbines and mentioned the interesting fact that in the city of Franklin he had been a classmate of Elihu Thomson.

MR. C. R. HUNTLEY, in his own frank, hearty way that is so taking with a large body of men, spoke in response to calls that would not be quieted, and said that while, like many others, he had some years before doubted the coming of Niagara power to Buffalo, he was glad and proud now to be helping in its introduction; and he elicited hearty cheers by his happy references to Messrs. Brush, Thomson, Sprague, Nichols, Lawrence, and others.

MR. C. F. BRUSH then said a few kind, congratulatory words, and was emulated in brevity by his table neighbor,

PROF. ELIHU THOMSON, who also met with a most enthusiastic reception. He paid his colleague in invention, Mr. Brush, a graceful compliment as the man who had taught them all long distance transmission, and he went on to speak highly of the prospects for the growth of Buffalo with the help of Niagara power.

Speeches were then made in rapid succession by Messrs. H. H. Littell, John N. Scatcherd, Ald. Smither, T. T. Ramsdell, G. Bleistein, and Congressman Mahany, who brought the oratorical proceedings to a close by a charming burst of eloquence in honor of electrical inventors. The banqueters dispersed about 2:30 a. m.

The record of this great event would not be complete without expression of regret of the absence caused by bereavement, of Prof. A. G. Bell, who has recently lost his mother, and of Mr. W. B. Rankine, secreary of the Niagara Power Company, who mourns the death of his father. Mr. Rankine has done so much in the promotion and prosecution of the Niagara enterprise that it is impossible to think of any stage of it without recalling his ever active and energetic share in the work. He was among those who might with propriety, if they chose, regard the banquet as serving to mark a personal triumph.

A SAW MILL OPERATED BY THREE-PHASE MOTORS.

The saw mill of the American River Land and Lumber Co., which is located close to the power house at Folsom, Cal., of the Folsom-Sacramento Power Transmission, was started successfully on the 1st of December, cutting fifty thousand feet of lumber per day. The saw mill is the first in the country which is operated by electricity.

The current is three phase taken from the power house at Folsom and the motors are all of the induction type, the installation having been made by the General Electric Company. The motors employed are one of 75 horse-power, one of 50 horse-power, both running at 720 volts; three of 30 horse-power, and one of 5 horse-power, operating at 200 volts.

THE HARTFORD ELECTRIC LIGHT CO'S NEW STORAGE BATTERY EQUIPMENT.

ONE of the most interesting station equipments in the United States is that which has gradually taken shape in the work of the Hartford (Conn.) Electric Light Co. As already pointed out in these columns, the company has for some time availed itself of a water power by utilizing a fall of the Farmington River, and bringing in current at 10,000 volts for a distance of nearly 11 miles by the three-phase system. The power at present available is about 1,200 kilowatts, which is generated at 500 volts in two turbine driven alternators of 600 kilowatts each.

Heretofore the power thus transmitted was availed of only at the time of greatest load, but by the introduction of a storage battery it is now practically used continuously and the local plant at Hartford correspondingly relieved, one of the stations being shut down entirely after 6 p. m., and depending entirely on the storage battery as the source of current. The transmitted power is used in three ways. A part of it, after passing through the transformers, goes directly into the lines for some of the incandescent lighting in the central part of the city. The transformation is from 10,000 volts down to 2,000 volts. A large part of the current after being reduced in Pearl street from 10,000 volts to 2,000 volts, goes to the State street station and is there passed through a rotary transformer, which converts it into the direct current, for charging the storage battery, and for supplying power at either 110 or 220 volts over the three-wire system under ground as far as it extends in Central Square, Main street and Asylum street. Any surplus of power not used at the central station becomes available for operating the 600 kilowatt motor generator at the Pearl street station, which is illustrated in Fig. 1.

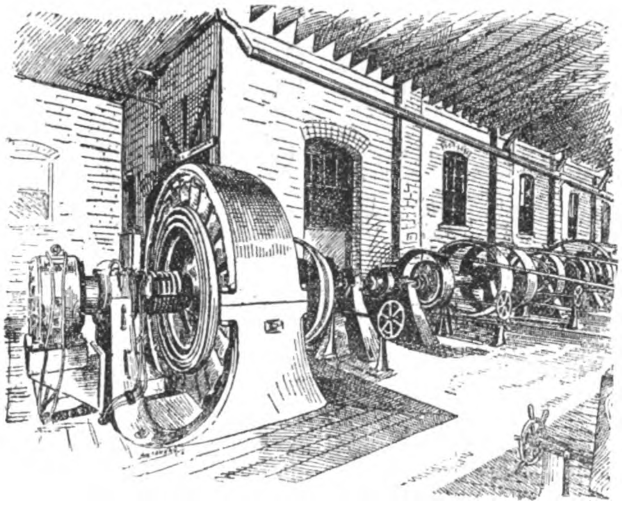

FIG. 1.—WESTINGHOUSE MOTOR GENERATOR, HARTFORD STATION.

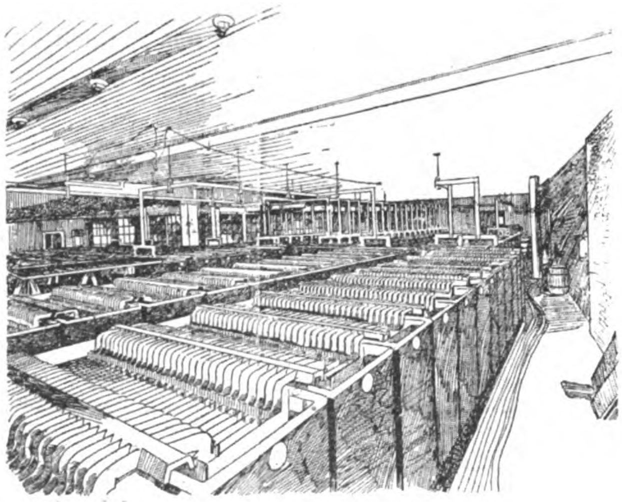

FIG. 2.—CHLORIDE STORAGE BATTERY ROOM.

The storage battery, Fig. 2, has a capacity of 500 horsepower hours, or 10,000 ampere hours.

Fig. 3 is a diagram showing the station operation for December 12 last. The figures at the sides of the diagrams represent amperes, and the shaded areas tell the story of inflow and outflow of electric current to and from the station from midnight to midnight. The line enclosing "B" and "C" spaces shows the current which went from either the rotary converters or the storage battery into the lines. As shown, the consumption has fallen at midnight to 350 amperes (notice left end of line enclosing "B" space). The outflow runs along at about that rate until 6 a. m., when it begins to jump, and at 8:30 a. m. it has gone up to 1,550 amperes. During all the time from midnight until 8 o'clock the current from the river (represented by "A") has been flowing into the battery, but now it comes to the aid of the transformer and helps it out, taking the peak of the load for about an hour and a half. Then the demand from the lines runs along at between 1,300 and 1,400 amperes until noon, when it suddenly takes a drop to 750 amperes—so many lights and motors are turned off between noon and 1 p. m. During that hour the current begins to flow into the battery again. But from 1 till 3:30 the river current is all required by the lines and the battery gets nothing. At that hour the rotary transformer is stopped and the battery is allowed to take the whole load until 11 p. m. Between 4 and 5 the load runs up to 2,300 amperes. Then it drops off rapidly and gets down to 1,500 amperes a few minutes after 6. There is another lower peak to be surmounted at 8 and then the consumption falls off rapidly until 11. At that hour the drawing of current from the battery stops and charging begins again, the current from the lines being obtained direct from the rotary transformer.

Formerly the river power could be utilized only during the hours when the arc lights and incandescents were actually in use. Now it can be used every hour in the day when there is water in the river, and as this added power costs absolutely nothing, the storage battery plant is, it is claimed, to pay for itself in three years at the furthest.

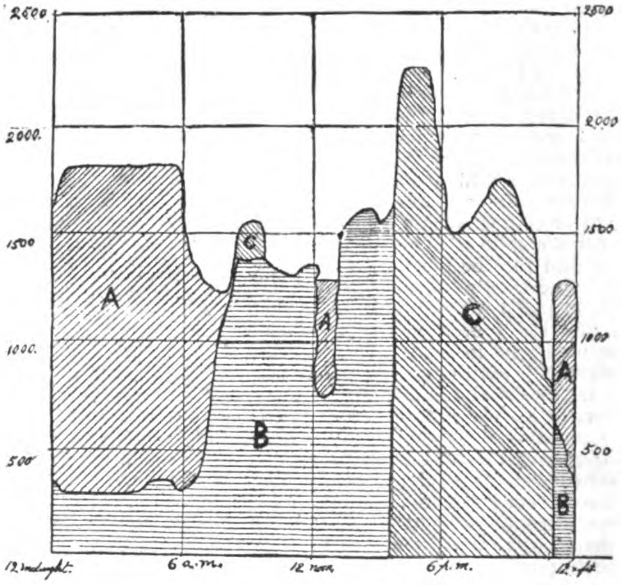

FIG. 3.—LOAD DIAGRAM OF HARTFORD ELECTRIC LIGHT STATION.

The battery cells are 130 in number, weighing in all, 300 tons.

MR. H. C. PAYNE AND THE POSTMASTER GENERALSHIP.

President J. E. Keelyn, of the Western Telephone Construction Co., is circulating petitions against making Mr. H. C. Payne, of Wisconsin, Postmaster-General in the new administration, and is addressing these memorials to Mr. McKinley. The ground taken is that Mr. Payne is a deeply-dyed Bell telephone man and a lobbyist for monopoly. It may be noted that Secretary Olney, in President Cleveland's cabinet, is or was counsel for the American Bell Telephone Co.

MUMFORD, N. Y.—The town of Mumford is now lighted by a plant consisting of a 110-volt dynamo, 7 arcs and 75 incandescents run by water power.

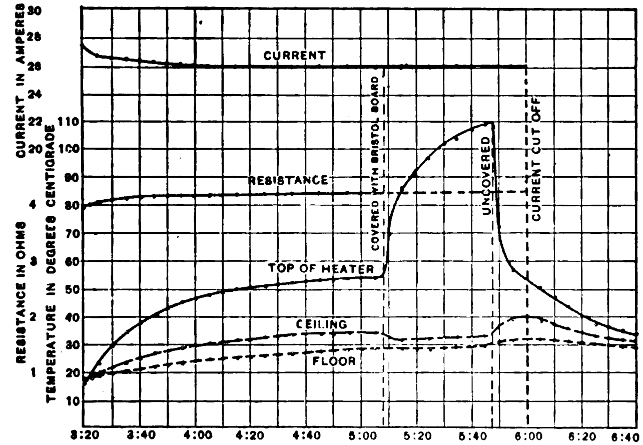
ELECTRIC HEATING.

INCANDESCENT LAMPS vs. COMMERCIAL HEATERS.

BY E. Y. PORTER AND C. D. WARNER.

WHILE engaged in a series of experiments in electric heating at the University of Nebraska, in the spring of 1896, it occurred to the authors that a comparison of the heating effect of incandescent lamps with that of the usual form of electric heaters might develop some interesting facts.

In accordance with this idea a 3½ horse-power car heater of the Whittingham system was selected as representative of the electric heaters now on the market, and was subjected to a careful test. This heater consists of twelve wrought iron tubes, one inch in diameter and six feet long, having a total radiating surface of 2,592 square inches. Each tube contains three strands of No. 20 B. & S. German silver wire, twisted together and inserted in a ¼-inch glass tube, the whole being filled in with clean sand.



Electrical Engineer

FIG. 1.—TEST OF 3½ H. P. ELECTRIC HEATER.

For the purpose of testing, the heater was surrounded on the ends and sides by a box 1 foot by 2 feet by 6 feet 4 inches. This box was made by stretching heavy manila paper over a wooden form so as to leave one inch dead air space in the walls. The heater and box were elevated 4 inches from the floor to allow free circulation of air through the heater.

The room in which the test was made is 10 feet long, 7 feet 9 inches wide, 16 feet 8 inches to the plate, and 19 feet 2 inches to the ridge, giving a total volume of 1,396 cubic feet. It contains one window and three doors with transoms. The heat capacity of the extra volume of air in the doorways and windows was assumed to be equal to that of the heater box and ladder. The room is situated in the center of the Engineering Building, on the second floor, and, except for the roof, is entirely surrounded by other rooms where the temperature was practically constant throughout the test. The walls, floor and doors were of pitch pine. The area of wood was 755.5 square feet. The area of glass in windows and transoms was 25.3 square feet.

The temperature was taken by means of three Centigrade thermometers, one 3 in. from the floor, another at the top of the box, 18 in. directly above the heater, and the third suspended from the ceiling. A metal vane supported the second thermometer above the heater and directed the hot air against it. When the temperature above the heater became nearly constant, the box was covered with sheets of heavy bristol board. In order to read the thermometers it was necessary to separate the boards about ½ inch for a moment.

Readings were taken at five minute intervals, from which the accompanying curves have been plotted.

Referring to the curves, Fig. 1, it is seen that as the temperature at the floor and ceiling gradually rises, the difference between them constantly increases to the point where the heater was covered. Then the temperature at the ceiling dropped about 2½ degs., while the floor temperature was slightly affected. When the heater was uncovered it was seen that both ceiling and floor temperature rose; the temperature at the ceiling, however, rising much higher than the other, and the curves reaching their maximum difference twelve minutes after uncovering. When the current is cut off, both curves fall and approach each other. It may be noted in this connection that the more rapidly the heat is given off, the greater is the difference in temperature between the top and bottom of the room.

The curve of temperature at top of heater shows a very gradual rise. This indicates considerable heat capacity in the heater. It will be noticed that the difference between this curve and the floor temperature curve becomes nearly constant after an hour's run. On uncovering the heater the rise of temperature is quite rapid, and would probably have reached a constant difference as before, if it had been allowed to continue long enough. When the heater was uncovered the up-rush of heated air caused the sudden rise of temperature at the ceiling, and temperature at top of heater dropped within twelve minutes, even below the former point. The temperature drops gradually after the current is cut off and approaches the other two curves. If it had not been for the heat capacity, the difference between the curves would have diminished much more rapidly.

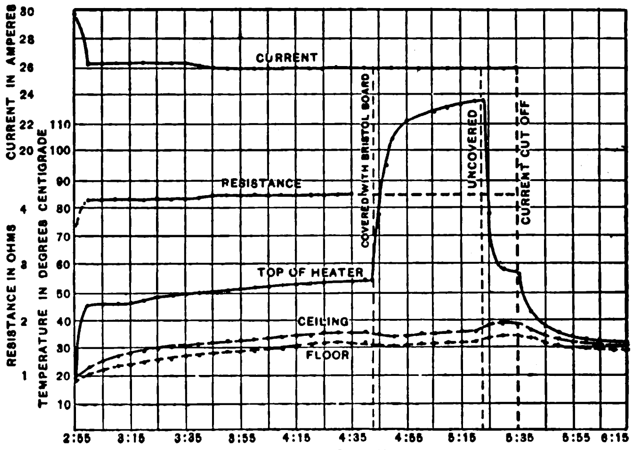
In the upper part of the diagram are shown the current and resistance curves, the voltage being kept constant. The small rise of resistance as the heater warmed up, means a low temperature coefficient. We might expect that when the heater is covered the resistance of the wire would rise still higher. But the fact that it does not, proves that there is no perceptible rise of temperature in the resistance wires themselves. The low temperature coefficient, by permitting a constant current to flow under wide difference of temperature, does not show the self regulating effect so noticeable in iron wire heaters.

Summarizing the results of the tests, we have:

Mean watts	2,881
Time of run	2 hrs. 40 min.
Watt hours	7,683
B. T. units consumed	26,215
B. T. units given off by one person, 2 hrs. 40 min.	510
Mean temperature of room at beginning	19° C.
Mean temperature of room when current was shut off	35.55° C.
Mean rise of temperature	16.55° C.
Volume of air in room	1,396 cubic feet
Watts given off per square inch radiating surface	0.9

In experimenting with incandescent lamps for atmospheric heating, a bank of seventy-five 16 candle-power, 110 volt lamps, arranged in three parallel rows was used. This heater was of approximately the same size as the car heater, and was tested under exactly similar conditions, and corresponding readings were taken.

When the current was turned on, about seventy-two lamps were in circuit, but enough were immediately turned out to reduce the current to the same amount as that at which the heater ran during the fore part of the test, and later, other lamps were turned out, so that the average energy delivered to each heater was very nearly the same, the difference being within fifteen hundredths of one per cent. The temperatures at starting were nearly the same, in fact the weather conditions were almost identical on both days.



Electrical Engineer

FIG. 2.—TEST OF INCANDESCENT LAMPS CONSUMING 3½ H. P.

The ceiling and floor temperature curves, Fig. 2, rise gradually but more rapidly than before, and reach somewhat higher points before the box is covered. It is to be noticed that the ceiling temperature quickly reaches a point about four degrees above that of the floor and maintains this constant difference until the box is covered, which shows a more even distribution of heat throughout the room than do the corresponding curves of the car heater, an important feature of atmospheric heating.

When the supply of heat was cut off both curves dropped slightly, the ceiling temperature more than the floor. Again, on uncovering the box, the ceiling temperature rose quickly, but did not go as high as with the iron heater and did not exceed four degrees rise above the floor temperature, which as before rose slowly. When the current was cut off all three curves dropped more suddenly than with the other heater and approached each other more closely.

Referring to the curves of temperatures above the heater, the most noticeable thing is the very sudden rise of temprature, showing that its heat capacity is very small. The large current at starting, of course, caused a more rapid rise than would otherwise have occurred, but the form of the curve indicates that this effect did not last more than about fifteen minutes, and within this time the curve had reached a height above the floor temperature which remained practically constant to the point of covering the box. At this point the temperature shot up more quickly than with the iron heater, and within twelve minutes it reached the maximum point of the other curve. This also shows that it had small heat capacity, as does the rapid fall on uncovering the box, and again on cutting off the current.

Summarizing the results of the test, we have:

Mean watts	2,885
Watts per square inch radiating surface of heater, about	1.6
Time of run	20 hrs. 40 min.
Watt hours	7,695
B. T. units consumed	26,255
B. T. units given off by one person, 2 hrs. 40 min	510
Mean temperature of room at beginning	19.3° C.
Mean temperature when current was shut off	35.85° C.
Difference of mean temperatures	16.55° C.
Volume of air in room	1,396 cubic feet

LETTERS TO THE EDITOR

GASOLINE ENGINES AND FIRE INSURANCE.

WITH the introduction of gasoline engines one of the first things to be considered by the purchaser was, How will its use affect my insurance? This question pressed itself, with equal force, upon the fire underwriters. Experience has shown that much of the prejudice against the use of gasoline engines is without foundation. As an evidence of the correctness of this statement, the infrequency of fires resulting from gasoline engines is ample proof. It is stated by parties in a position to know, that not a single loss has been reported, to the State Board of Underwriters, of Illinois, directly attributable to a gasoline engine, this notwithstanding there are hundreds of such engines in use, particularly in grain elevators, and that they are, in the main, attended by help unskilled in the matter of machinery.

In view of the foregoing facts, it would seem that the insurance companies are charging excessive rates on property where gasoline engines are used. There are a number of gasoline engines on the market, the manufacturers and users of which know to a certainty, that there is not so much danger in the use of, than from a kerosine lamp; and yet the user has to pay "50 cents additional if engine is located in building, and gasoline supplied by air pressure." Why such a charge is made is difficult to understand, as, if the engine is properly installed and connected to a gasoline tank, the gasoline being pumped as required for use, no part of the gasoline coming in contact with the atmosphere in building, the danger from fire is, beyond question, very remote. Notwithstanding that we hear and read very frequently of fires from gasoline stoves, their use is permitted without extra charge, while the owner of a gasoline engine must pay dearly for employing one of the safest and most desirable motors available.

With the increasing demand for gasoline engines for various uses, including electric lighting in isolated plants, the question of insurance rates rises in importance; and when much of the existing prejudice has been removed, more favorable rates are sure to be obtained by the insured. As a matter of fact, gasoline engines, when properly installed and connected, are practically free from danger of originating fires. It would be interesting to learn the reasons for some of the charges fixed by the insurance companies on gasoline engine risks.

J. M. H.

Chicago, January 11, 1897.

TELEPHONY AND TELEGRAPHY

PACIFIC CABLE PROJECTS.

A special dispatch from Washington of Jan. 15 says: The Pacific cable project was considered again to-day by the House Committee on Commerce, which listened to a statement by Gen. Swayne on behalf of the Pacific Cable Company, of New Jersey, in which he is associated with Col. Spalding, of Honolulu; D. Ogden Mills, James J. Hill, Abram S. Hewitt, and other capitalists. Gen. Swayne urged the House Committee to recommend the Senate bill, which authorizes the Postmaster-General to contract for a cable from the Pacific Coast to Japan by way of the Hawaiian Islands, with an annual subsidy not exceeding $160,000. A bill has been reported to the House for a subsidy of $100,000 a year to the Pacific Cable Company, of New York, in which James Scrymser and J. Pierpont Morgan are interested.

The recent colonial conference which decided upon the project of a British cable from Vancouver to Japan by way of Australia and Honolulu, Gen. Swayne said, endangered the success of an American enterprise unless immediate steps were to be taken by Congress. He urged the House to adopt a plan which would insure competition for the subsidy, believing that no bill giving a subsidy to a particular company could succeed while it was known that other responsible parties desired to bid. That part of the project of the Scrymser company which contemplates a cable from Japan to China, Gen. Swayne held to be unnecessary, because two established cables fill that field now. Nor did he believe a cable could be finished to Honolulu within a year, and to Japan within eighteen months, as that company offers to do. He offered on behalf of the corporation which he represents to deed Col. Spalding's concessions from the Hawaiian government to the successful bidder under any bill which provided for competition.

A special dispatch of Jan. 15 from Montreal says: A dispatch from London received here says that it is currently reported that the route chosen for the Pacific cable is Vancouver to Fanning Island, Fiji Islands, Norfolk Island, thence to New Zealand and Queensland.

POLICE WIRES IN BROOKLYN.

Police Telegraph Superintendent F. C. Mason, of Brooklyn, submitted his annual report to Superintendent McKelvey, of the Police Department, last week. It shows that 210,370 messages were handled by the operators at headquarters during the year. There are in use at present 440 telephone and 353 patrol boxes and 569 miles of wire, of which 350 are on poles, mainly in the suburban districts, and 219 attached to the elevated railroad structures and underground.

Mr. Mason strongly recommends that early steps be taken to put all the police wires under ground. The work of the telegraph bureau, according to Commissioner Welles and Superintendent McKelvey, reflects credit on Mr. Mason and his corps of operators, all of whom are to be continued in their places in the Greater New York Police Department.

A POSTAL TELEGRAPHIC SPEED CONTEST.

A CONTEST of speed was recently carried out between operators of the Postal-Telegraph Company in New York, Chicago and Pittsburg, which demonstrates the work that can be accomplished by the use of the Morse system under the most favorable conditions of men and apparatus. The contestants were three expert telegraph operators in each of the three cities.

Pittsburg sent into New York during five hours 341 messages, containing 10,216 words, or an average of 68 1-5 messages per hour, which was the best average for the entire period attained during the contest.

New York sent to Pittsburg in three hours 200 messages, an average of 66⅔ messages per hour, containing 5,605 words. During the first part of the test New York sent Pittsburg 102 messages in 90 minutes, an average of 68½ messages per hour. While this was the fastest time made in an hour and thirty minutes, Pittsburg operators surpassed the others by their uniform work from beginning to end, and at no time fell below a message a minute.

The result of the contest will be appreciated when it is understood that 30 messages an hour on long circuits is considered fair work, and 40 messages is considered good, while 50 messages an hour has been regarded as the limit of the fastest sender for many years.

GERMANY JOINED TO SOUTH AMERICA BY CABLE.

A submarine cable has been completed from Emden, Prussia, to Vigo, Spain, which links the German telegraphic system with the South American and other systems. Capital has been furnished by an Anglo-German syndicate for the construction of the first section of a submarine cable between Germany and the United States via the Azores.

ELECTRIC TRANSPORTATION

GLASGOW STREET RAILWAY COMMISSIONS REPORT.

It appears to be a settled thing that Glasgow is to have the overhead trolley. The municipal authorities there have been engaged upon the transportation problem for some time, and last year sent a commission to the United States to investigate the whole subject. These gentlemen have submitted an elaborate report, which, after discussing storage batteries, oil and gas motors, compressed air, electric open-conduit and underground systems, and other devices, decides in favor of the overhead trolley. They say: "After seeing the best overhead construction for the electric overhead system, and considering its vast importance as a means of rapid transit of passengers on city and suburban streets and roads, we are perfectly reconciled to it, and feel that it only wants to be seen in use to be appreciated. It of course goes without saying that if a system as good and as cheap can be had without any overhead construction, we should prefer it. But there is none such known at present. And we feel sure that if the citizens saw this system of rapid transit in operation on the Springburn route—comfortable cars, propelled, illuminated, and heated by the same power—they would not for a moment object to the appearances of neat poles to carry the wires, especially if the old lamp-posts were done away with, and the trolley-poles made use of for electrically lighting the streets. We believe the citizens would soon conclude that it was beautiful as a whole."

THE HILLTOP FIFFTEEN PER CENT. GRADE AT PITTSBURG.

The latest electric railroad in Pittsburg, the Hilltop line, was opened there last week. It is a branch of the Pittsburg and Birmingham Traction Company, which connects the old city of Pittsburg with those districts situated on the southern shore of the Monongahela River. The Hilltop line runs across the Monongahela over the Smithfield street bridge and goes up Brownsville avenue, which road has a grade of 15 per cent. By this road the suburb of Knoxville is reached. The line has been in great demand because it will afford rapid transit facilities to about 50,000 people who have hitherto been entirely dependent upon inclines and such walking accommodations as unpaved streets afforded.

The Birmingham Traction Company operates twenty-two cars on the Hilltop line. The cars are equipped with two 50 horse-power Westinghouse motors and controllers. To take care of the increased traffic occasioned by the opening of this line, the Birmingham Traction Company has recently remodeled and re-equipped its power house at Thirty-first and Carson streets. This power house was equipped with generators of an older make. They have all been thrown out and three new Westinghouse machines take their place.

STREET CARS PAINTED GREEN.

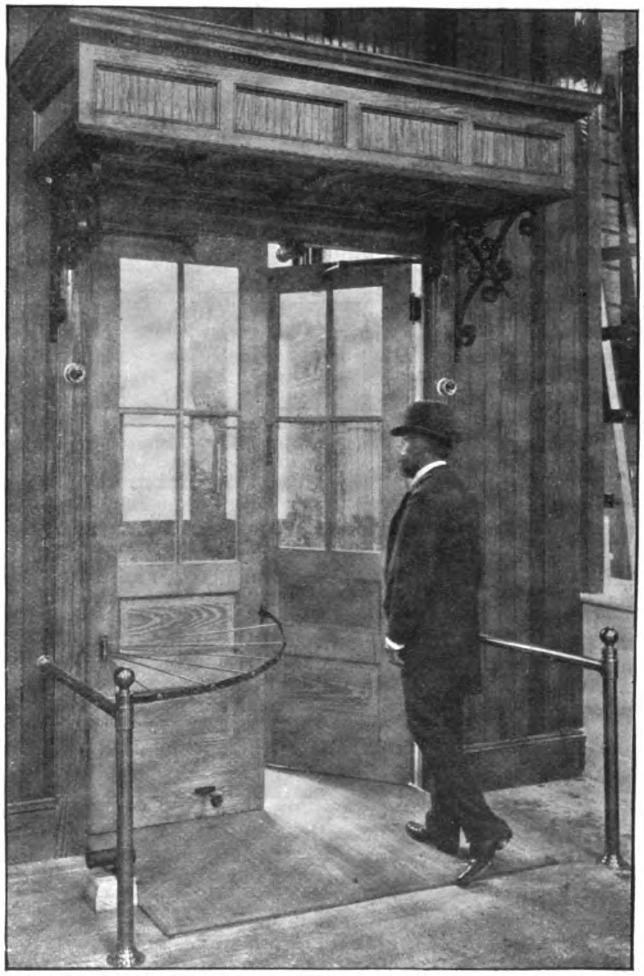
The man talking was from Boston, in New York on business involving a real estate deal. "When I began this business ten years ago," he was saying, " I didn't know as much as I do now. Neither did I know as much as would suggest to me the propriety of going in when it rained. For instance, I had got up a big thing in South Boston (where we have a tremendous Irish population) in the way of suburban properties, and I got a company to build a trolley car line to it. A rival of mine was doing something of the same sort in a different direction, but I knew I could give him four aces and beat him out of sight. His street car line was half a mile longer than mine to my property, and the location wasn't nearly so good. Just the same he walloped the everlasting pudding out of me, if you will excuse a Bostonianism, and did it in the simplest way possible. You see, I wasn't thinking, and when I ordered cars for my line I had them painted a beautiful orange to show how rich our subdivision was. The other chap, I guess to show what kind of a chump I was, had his cars painted a glorious green. The Irish did the rest. If you don't believe it you want to go out to my subdivision some time when you are in our town, if you can find it."

NEWS AND NOTES.

THE HICKS-TROY ELECTRIC DOOR OPENER.

Door checks have done much to relieve humanity from the nervous shocks engendered by slamming doors, but there is still wanted some device that will relieve one from the strain which most door checks and springs put upon the muscular system. Such a device, it may be recalled, was exhibited at the World's Fair in 1893 and described by us at the time. It is the invention of Messrs. Oliver Hicks and R. F. Troy, of the Hicks-Troy Electric Door Company, of Chicago, and two of the door-openers are now in operation, one in the city market at Springfield, Mass., and another in the State street lunch room of H. H. Kohlsaat & Co., Chicago. The doors are both double, fitted to pass in one person to the right and another in the opposite direction at the left. Fig. 1 is a photographic reproduction of the Springfield doors.

As one steps on the mat at the entrance, that door directly in front swings noiselessly open from him. If another person is following close behind, the door does not swing in one's face, but remains open until that person and any others have passed through, when it immediately closes gently.



Hicks-Troy Electric Door Opener.

The mechanism of the door consists of a motor, worm-gear, magnets, clutches, with a 110 volt current and a system of wiring. The cabinet over the door on the inside contains the motor, magnets, clutches, etc. Through the bottom of this cabinet depend arms, one connecting each wing with its corresponding motor mechanism and through which the power is applied to move it. Through the doorway is spread a specially designed mat, connected by wires with the electric mechanism in the cabinet. When the doors are closed, stepping upon the mat closes the circuit through one or more of the many metal circuit closers, causing the armature of one mat—called the mat magnet—to be depressed and an electric switch connected with it to send a current through the clutch magnet, releasing the pulley upon which is wound the belt through which the motor closes the door and the springs pull the door open. Upon stepping from the mat, the circuit is broken through the mat magnet, and consequently the switch attached to its armature cuts the current out of the clutch magnet, leaving the belt pulley secured to its shaft and the motor and the motor current is turned on. The motor revolves and winds the door shut, at the same time winding up the springs that are to open the door for the next operation. Pressure on the same spot on the mat, at one time controls one door, and at another moment the other door, depending on the position of the doors and whether the passenger is entering or leaving the building.

The switch Y, Fig. 2, being on, the door being in a closed position, the operation is as follows: The passer through the doorway upon stepping upon the mat depresses one or more circuit closers d, completing the circuit through ee, and cc, energizing the coils UU; the armature Z, is depressed, switching the current through ff, to the clutch magnet, GG, and drawing to it its armature I. The spool F is now free to revolve and the springs R, through the arms K and O, pull open the door. Upon the passer through stepping from the mat the contact is broken at the circuit closer d, the magnet armature Z, returns to its normal position, the circuit through ff is broken at T, the clutch armature I is released and the spring J, upon the shaft, binds the spool to the disk C, and at the same time the circuit is closed by the magnet switch at T, through gg, to the motor; the switch S being on, the motor revolves and the door is closed ready for the next operation; hh is the return wire for a clutch magnet, motor and mat magnet. As the door nears its closed position the motor switch S, operated by the rod b, and arm K, cuts out the current from the motor A. It will thus be seen that when the door is in a closed position no current is being used.

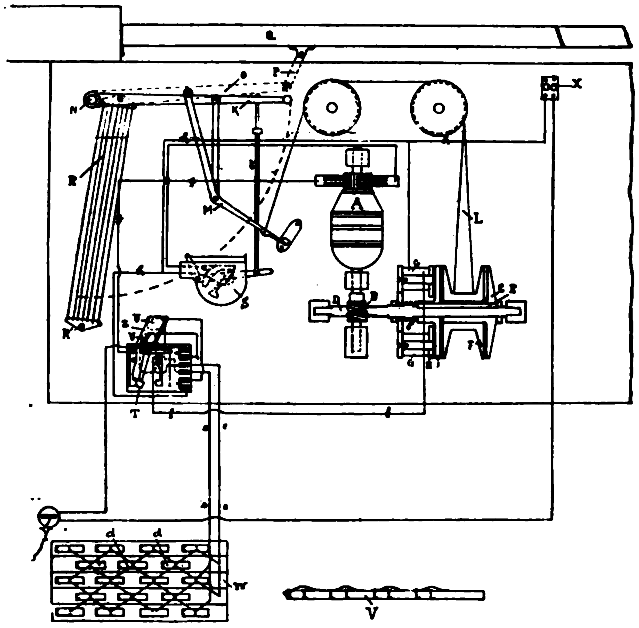


Fig. 2.—Electric Door Opener Mechanism.

The 110 volt direct current is used, the motor taking about 2½ amperes, the clutch magnet about 1/4 of an ampere, and the motor magnet ⅛ of an ampere. The electric mat proper is thoroughly insulated top and bottom by rubber and the whole is encased in a water tight zinc covering. This is then laid upon a raised wood flooring, the whole being covered with a corrugated rubber mat.

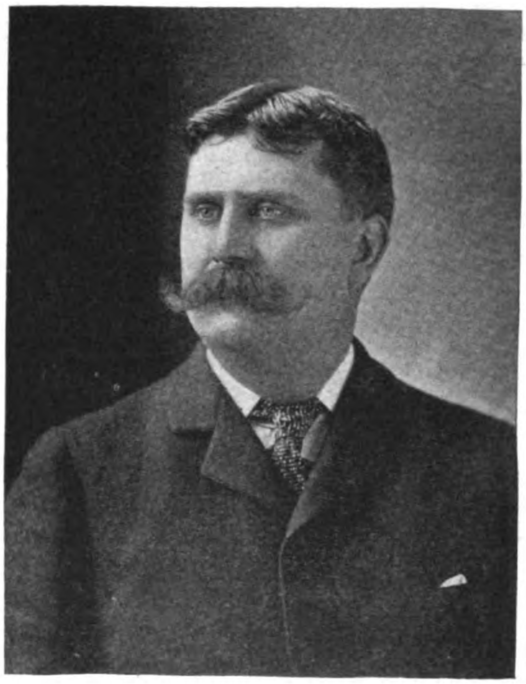
All the rapidly moving parts such as motor bearings, worm and gear, are self oiling. The mechanism shown is for one of a set of double doors and in all important details is the same as required to operate a single door.

E. A. WESTERFIELD has been appointed manager of the Chicago office of the Postal Telegraph-Cable Company to succeed G. E. Paine, promoted to the superintendency of a Western division.

PERSONAL

MR. J. M. HILL.

Mr. JOSEPH M. HILL, whose potrait is shown in this issue, has been appointed manager of the new branch of the Bryan Marsh Co., in Chicago, which will be opened on February 1. Mr. Hill has for some time acted as Chicago representative of the Columbia Incandescent Lamp Co., which position he has resigned. He also is sales agent for the Wagner Electric Manufacturing Co., and will continue to look after the interests of that company. Mr. Hill is very well known in electrical circles throughout the West, and is most deservedly popular with all those who know him, and the Bryan Marsh Co. are to be congratulated upon having secured the services of so valuable a representative.



J. M. Hill.

OBITUARY

COL. C. H. BANES.

Colonel Charles H. Banes, president of the Market Street National Bank of Philadelphia, and a leading business man of that city, died on January 15, after a protracted illness. He was born in Philadelphia on October 24, 1831, and when the civil war came became Captain of a company in the Twenty-second Regiment, Pennsylvania Volunteers. Three times he was promoted for gallant service on the field. In December, 1862, he was appointed Assistant Adjutant General, and was confirmed by the Senate in May, 1863. During the latter year he was breveted Major, and in 1864 was breveted Lieutenant Colonel. He was in the field until June, 1864, being wounded three times and participating in forty battles. He was very active in Philadelphia affairs, and will be remembered by electrical engineers as the president of the successful Electrical Exhibition in that city in 1884. He was afterwards prominently associated with the Sawyer-Mann Electric Company for a short time.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JAN. 5, 1897.

Alarms and Signals:—

ELECTRIC ALARM DEVICE. G. V. Trott, Chicago, Ill., 574,856. Filed April 10, 1896.

Burglar alarm.

Connectors, Conduits and Insulators:—

SUBWAY CONDUIT. W. H. Johnston, St. Louis, Mo., 574,430. Filed Aug. 15, 1896.

Means for drawing conducting wires through conduits.

INSULATOR. B. D. B. Smock, Wickatunk, N. J., 574,828. Filed March 10, 1896.

Consists of a body portion with an opening to receive a wire and a ribbed wedge adapted to be inserted to hold the wire therein.

Lamps and Appurtenances:—

MANUFACTURE OF INCANDESCENT ELECTRIC LAMPS. T. B. Atterbury, Pittsburg, Pa., 574,370. Filed Dec. 18, 1894.

Consists in cementing an underground perforated stopper in the lamp by vitrifiable enamel or cement, and then heating it to vitrify the enamel.

Measurements:—

ELECTRIC METER FOR ALTERNATING CURRENTS. G. F. Packard, Fort Wayne, Ind., 574,565. Filed Oct. 26, 1896.

Combines a rotary armature provided with a plurality of radial vanes, and a counting or registering train connected with the armature.

ELECTRICAL MEASURING AND INDICATING APPARATUS. J. F. Kelly, Pittsfield, Mass., 574,739. Filed June 16, 1896.

Comprises a vibrating needle and stationary quadrants separated from each other by a wall of insulating material.

Miscellaneous:—

ELECTRIC CLOCK. C. M. Crook, Chicago, Ill., 574,669. Filed Dec. 12, 1895.

Operated by weights wound by the force of electric currents operating through electro magnets on a winding device.

METHOD OF ELECTROLYTICALLY UNITING GLASS TILES INTO A BODY. W. H. Winslow, Chicago, Ill., 574,843. Filed Nov. 2, 1896.

Consists in arranging the tiles in the order desired and then electrolytically depositing metal around their edges.

ELECTRICALLY HEATED SAD IRON. W. S. Hadaway, Jr., New York, 574,536. Filed April 7, 1896.

Embodies an electric heating conductor composed of helical convolutions arranged in three or more graduated sections.

AUTOMATICALLY CONTROLLED ELECTRIC OVEN. W. S. Hadaway, Jr., New York., 574,537. Filed May 4, 1896.

Provides an automatic switch, operated by variations of the temperature of the heated surface, to cut coil sections of the heating conductor in and out of circuit.

ELECTRIC HEATER. J. E. Meek, New York, 574,745. Filed March 5, 1896.

Means to obviate the use of a rheostat.

Railways and Appliances:—

ELECTRIC RAILWAY TROLLEY. E. M. Bentley, New York, 574,377. Filed July 28, 1896.

Combines a supporting arm upwardly spring pressed, a guideway on the outer end of the arm, a pivoted tip or end section movable on the guideway, a contact wheel on its outer end and a spring for pressing the wheel into engagement with a line conductor.

ELECTRIC PROPULSION OF VEHICLES. W. A. Butler, New York, 574,388. Filed March 19, 1895.

A steam locomotive in which the water is heated electrically.

SELF-ADJUSTING TROLLEY WHEEL. G. W. Duryea and T. W. Thompson, Brooklyn, N. Y., 574,527. Filed Aug. 3, 1896.

Consists of a trolley wheel provided with guiding arms and automatically acting devices connected therewith for finding the trolley wire.

ELECTRIC RAILWAY. W. M. Schlesinger, Philadelphia, Pa., 574,632. Filed Oct. 12, 1887.

"Third rail" system.

TROLLEY. W. L. Pepper, Philadelphia, Pa., 574,819. Filed April 2, 1895.

Comprises oppositely disposed trolley arms, each constructed in pivoted sections, the upper sections of the arms being pivoted to the trolley wheel and the lower sections of the arms pivotally attached to a support.

Secondary Batteries:—

SECONDARY BATTERY AND PROCESS OF FORMING SAME. G. W. Harris and R. J. Holland, New York, 574,417. Filed Jan. 30, 1896.

Consists of an open work plate composed of oppositely inclined intersecting ribs and grooves on its opposite sides.

SECONDARY BATTERY SUPPORT OR GRID. J. J. Rooney, Brooklyn, N. Y., 574,826. Filed Feb. 12, 1896.

Layers of strips of wool felt laid together in sets of rows which cross each other so as to form pockets or holes between the rows. See issue of Jan. 13.

Telephones:—

CIRCUIT FOR ANNUNCIATORS OF TELEPHONE LINES. C. E. Scribner, Chicago, Ill., and F. R. McBerty, Downer's Grove, Ill., 574,579. Filed May 14, 1896.

Details of construction.

TELEPHONE SWITCHBOARD. H. J. Swarts, Knoxville, Tenn., 574,642. Filed Dec. 24, 1895.

Comprises a table having a central opening to admit an operator, subscriber's line plugs located on the table around the opening and means for receiving two plugs to connect their respective wires.

TELEPHONE RECEIVER. R. S. Barnum, Chicago, Ill., 574,654. Filed April 3, 1896

Comprises a magnet supporting bridge placed at the end of the receiver-case adjacent to and parallel with the diaphragm, screws inserted into the ends of the case beneath the bridge so as to form rests or stops therefor, notches and screws.

AUTOMATIC TELEPHONE EXCHANGE SYSTEM. L. G. Bowman, New York, 574,707. Filed July 10, 1896.

Details of construction and operation.

AGITATOR FOR TELEPHONE TRANSMITTERS. S. B. Rawson, Elyria, Ohio, 574,761. Filed Jan. 14, 1895.

The operation of the lever holding the receiver agitates the transmitter.

REPORTS OF COMPANIES

BUSINESS PROSPECTS.

IT was known that the balance of trade with foreign countries was in our favor, but it was not realized until last week that for the year 1896 exports had overtopped imports by the magnificent sum of $325,000,000. This is not in itself an indication of prosperity, but it exhibits such unquestionable soundness and such strict economy on the part of the nation, that there can be but one result from it in the near future. The stock market showed an immediate effect from the publication of the figures; one has to fear that exuberant optimism may now at once take the place of a not less absurd pessimism. Steady prosperity is hindered by these violent swings of the pendulum of business sentiment.

During the past week, 15,505 shares of General Electric were sold on the New York market, the gain in the period being from 33¾ up to 34¾. In Western Union there was also an advance, on sales of 10,523 shares, up to 85½. On the Boston market, Bell Telephone advanced during the week from 208 to 209½. These three quotations attest the general drift.

The Albany "Argus" is authority for the statement that the net earnings of the General Electric Co. in 1896 were $1,976,000, on a gross business of $13,300,000. This is, however, without confirmation, and as a matter of fact, the G. E. fiscal year does not close until the 31st inst., and the annual inventory is taken the first week in February. It is reported that the company may pay up back dividends on preferred stock at the rate of 5 per cent.

Turning to the proposed combination of the Fort Wayne Corporation and the Siemens-Halske Co., which we reported three weeks ago, it may be stated that matters are about as they were then, the final closing of the deal and the amount of capital depending upon agreement as to the valuation of the plants. Should the preliminary contracts be carried out, a strong company will emerge, as we stated, under Mr. McDonald's leadership. It is well known that the negotiations have been conducted under the diplomatic care of President Insull, of the Chicago Edison Co., but that gentleman declines to add to the information on the subject. The rumors that he is coming East and would bring Bergmann's into the deal, may be dismissed as idle talk, but with his intimate knowledge of manufacturing and his influential relations to the consuming market for apparatus, it will not be strange if he is on the board of the new company he has helped to create.

SOCIETY & CLUB NOTES

HORSELESS VEHICLES.

The American Institute of Electrical Engineers will discuss the above topic at its monthly meeting on January 20, at 12 West Thirty-first street.

MR. E. H. JOHNSON has just been elected president of the Magnetic Club of New York. The choice is most happy. It would be hard to find a man who better represents the telegrapher, master of his own art and capable of anything else in electricity.

AVON, N. Y.—At the annual business meeting of the Avon Electric Company, the following officers were elected: President, Dr. Cyrus Allen; secretary and treasurer, J. D. Carson; general manager, C. F. Whiting. Mr. R. G. Elliott is the engineer.

LEGAL NOTES

THOMSON-HOUSTON TROLLEY SUIT WON.

Judge Acheson, at Pittsburg, on January 14, handed down a decision in the United States Circuit Court suit of the Thomson-Houston Electric Company against the Johnson Company and a number of other electrical concerns. The suit is based on an alleged infringement of improvements in traveling contacts for electric railways. The court holds that the claim of an infringement is valid against three of the defendants, the Johnson Company, of Pittsburg, the Steel Motor Company and R. T. Lane.

RAILROAD COMPANIES CITED FOR ALLEGED INFRINGEMENT.

The Newark and South Orange Railway Companies have been cited to appear in the United States District Court at Trenton, N. J., to defend a suit for infringement of patents held by the Thomson-Houston Company. The Consolidated Traction Company is likewise made a defendant in the action.

TELEPHONE PLUG INFRINGEMENT.

In an opinion filed in the United States Circuit Court at Baltimore, Md., on Jan. 7, Judge Morris holds that the Chesapeake and Potomac Telephone Company has infringed the patent for a telephone plug belonging to Augustus G. Davis and awards Mr. Davis one cent damages and costs. The invention was patented by Henry C. Watts, January 17, 1880, and the patent will expire this month. The plug is used in telephone switchboards for establishing communication with the telephones of subscribers.

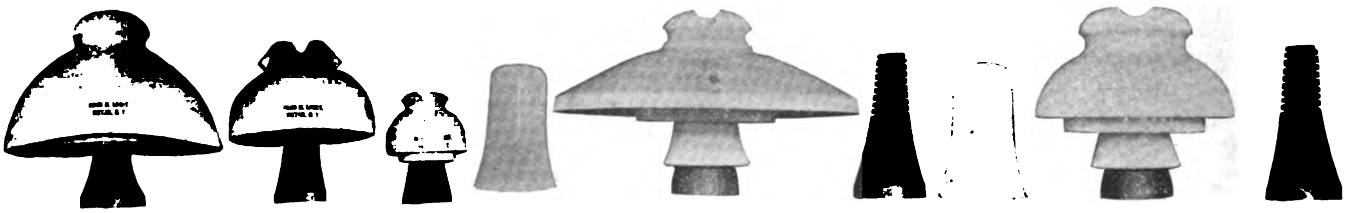
TRADE NOTES & NOVELTIES

LOCKE'S IMPROVED HIGH POTENTIAL INSULATORS.

THE introduction of high potential currents for long distance transmission has called for improved types of insulators capable of withstanding pressures of 30,000 volts and over, and Mr. Fred M. Locke, of Victor, N. Y,, as mentioned by us on Jan. 6, has recently brought out several types of insulators specially designed for this class of work. Our illustrations represent these various types. Their characteristic feature consists in the fact that they are made in two parts, the inner part of porcelain or glass, which are screwed together. By this construction it is claimed that the resistance to puncture is greatly increased, while at the same time the thickness of the two parts may be decreased, thus making the insulation lighter. In the accompanying illustrations the group, Fig. 1, at the left shows the parts of the insulator designed for 30,000 volts. Each part alone can stand 50,000 volts without puncture. The insulator is mounted on a locust pin boiled in paraffine oil and provided with the Locke steel pin which passes through the cross-arm.

The group, Fig. 2, shows an insulator of the same type with a specially wide outer petticoat.

Fig. 3 shows another group of insulators made by Mr. Locke, that at the left being the type used at Niagara Falls and de-equipments for 30 double-truck motor cars for the Oberschle-signed to carry 22,000 volts. These insulators have withstood potentials up to 70,000 volts without breaking down.



LOCKE INSULATORS FOR HIGH POTENTIAL ALTERNATE CURRENT TRANSMISSION.

MORE CONTRACTS FOR NIAGARA APPARATUS.

The Niagara power directors have authorized the officers of the company, in their discretion, to enter into contract with the I. P. Morris Company of Philadelphia, for the construction of five 5,000 horse-power turbines identical to those now in place made by that company; with the Westinghouse Company of Pittsburg for the construction of five 5,000 horse-power dynamos identical with those in use and constructed by this company, and with William Sellers & Co., of Philadelphia for the manufacture of five turbine governors and five sluice gates. No proposals were received for the construction of an addition to the power house. These will be received later. Secretary Rankine states that these contracts would aggregate over $500,000.

MICANITE INSULATION ON RAILWAY MOTORS.

The Mica Insulator Company have received the letter quoted below, as to the remarkable qualities of their micanite, tested under severe conditions of street railway use.

December 21, 1896.

Mica Insulator Company, Charles W. Jefferson, Manager.—Dear Sir: In March, 1894, you put a full body and slot insulation of micanite on one of our Edison No. 16 street car armatures, and the same was wound at once and put in service, and has been pretty steadily running ever since, the car having made over 50,000 miles. The armature has never given us any trouble in "body grounds" since it started, although it is of the "ring" type and is not protected by the motor frame, it being open to snow, slush or water from the wheels.

The wiring on this armature has just been burned out by a severe and continued overload, so heavy as to not only char the insulation of the wire, but to melt some of the wires themselves. On stripping off the wires, we were surprised to find the insulation of body and slots in apparently good order; and after fully stripping and testing we find it absolutely perfect, mechanically and electrically, and are now rewinding it, having done nothing to the insulation but to give it a coat of varnish and bake it. We consider this so remarkable a record that we think it only justice to you to inform you of it.

While the full micanite body of insulation costs several times more than our previous method of cloth, mica and paper, the results in freedom from armature "body grounds" and the ability to reuse the insulation indefinitely are points that will make us consider the use of micanite as essential in all our work for the future. Very truly yours, Schenectady Railway Company, per H. S. Cooper, Superintendent.

STANDARD AIR BRAKES IN EUROPE.

The Standard Air Brake Company has received from Germany, through its general representative, the Bergische Stahl-Industrie, of Berlin and Remscheid, an order for air-brake equipments for 30 double-truck motor cars for the Oberschlesische Dampfstrassenbahn. The company's motor-compressor type will be furnished, and in addition to the 30 outfits there is another order for 30 more to follow, making 60 cars in all. This road has been a steam road, but is about to be electrified. The company's foreign business is very active, and requests have been received recently for some three hundred additional equipments, for which it is expected contracts will be closed within a very short time. The company has not only increased its force, but has enlarged its facilities to meet the expanding business.

PORCELAIN-LINED OUTLET BOXES.

The Ward Leonard Electric Co., of Hoboken, N. J., have secured the exclusive right to the manufacture and sale of the various types of outlet boxes, switch boxes, junction boxes, floor boxes, cable boxes, drop cord boxes, receptacle boxes, etc., which have been known to the trade as the Mailloux, De Rycke, Krantz, Fountain and Soons boxes, and they are supplying the trade with these boxes porcelain lined instead of lined with paint as heretofore, the prices being in all cases equally as low as before and in many cases much lower.

The porcelain lining makes a perfect insulation for the purpose, as it is unaffected by heat, cold, acids, alkalies, oils, or, in fact, any chemicals or conditions met with in practice. The insulation is guaranteed to measure over 10 megohms and to resist 2,000 volts alternating e. m. f.

C & C APPARATUS IN THE SOUTH.

As an evidence of the confidence which is felt in the immediate development and advancement of business generally in the South, upon the part of manufacturers, we may state that the C & C Electric Co., of New York City, operating a large electrical manufacturing plant at Garwood, N. J., and one of the pioneer manufacturers of this country of electric motors, dynamos, etc., have just opened an office in Atlanta, Ga., at 630 Equitable building, of which Mr. Campbell Scott, formerly of Louisville, Ky., is manager. This office will be the headquarters of all the territory lying south of the Ohio and east of the Mississippi Rivers.

The C & C Company feel that the business conditions in the South now, are such that they will be fully justified in going to the expense of maintaining this office, by immediate returns in the shape of contracts for electric lighting and power plants. The C & C Company manufacture a full line of dynamos, generators, switchboards, elevators, controllers, etc.

SALES OF BALL ENGINES.

The Ball Engine Company, Erie, Pa., report the following shipments during the last thirty days: Shoenberger Steel Co., Pittsburg, Pa., one 150 horse-power and one 400 horse-power vertical direct connected; Chicago Public Library, Chicago, Ill., four 200 horse-power vertical cross compound and one 100 horse-power vertical cross compound; Nicopol-Mariopol Mining and Metallurgical Co., Mariopol, Russia, one 400 horse-power vertical cross compound, direct connected; to Mexico, five 25 horse-power engines; Jackson Street Railway Co., Jackson, Tenn., two 175 horse-power engines; Electric Installation Co., Geneva, Ill., one 100 horse-power engine and one 70 horse-power engine; Hammond building, Detroit, Mich., two 70 horse-power engines, direct connected; United Coke and Gas Co., Glassport, Pa., one 60 horse-power engine; Paul O. Stensland building, Chicago, one 125 horse-power engine direct connected; Crook, Horner & Co., Baltimore, Md., one 50 horse-power engine, direct connected; Church Home and Infirmary, Baltimore, Md., one 60 horse-power direct connected engine; Pine Ridge Indian Reservation, one 35 h.-p. engine, direct connected; Rosebud Indian Reservation, one 35 h.-p. engine, direct connected; Pennsylvania Tube Works, Pittsburg, Pa., one 60 horse-power engine; Junaluski Leather Co., Waynesville, N. C., one 50 horse-power engine; Wauwatosa County Insane Asylum, Wauwatosa, Wis., one 70 horse-power engine and one 110 horse-power engine; A. M. Fuller building, Chicago, one 70 horse-power engine.

GATES IRON WORKS OF CHICAGO.

The Gates Iron Works, of Chicago, announce their embarkment in the high-speed engine business with the Fischer-Gates single and four-valve self-oiling automatic engines, built according to the design and under the patents of Mr. Fred F. Fischer. Their product will be handled on the market by Messrs. Fischer & Whiteside, whose headquarters are at 700-702 Fischer Building, Chicago. Plans for extensive additions to the already very large plant of the Gates Iron Works are completed, and it is intended to push this branch of their business with the energy, experience, courtesy and business tact characteristic of this company, and they anticipate a large trade in the near future. The catalogue illustrating and describing the novel features of the Fischer-Gates engine, many of which are already familiar with the engineering fraternity, will be ready for distribution in a short time. Orders for these engines are already on their books. The reputation of this concern and that of the gentlemen who are associated with them will insure a high-class machine.

"IMPERIAL" LAMP AGENCY AND DEPOT IN CHICAGO.

MR. CONVERSE D. MARSH, president of the Bryan-Marsh Company, whose success in pushing boldly to the front their Imperial incandescent lamp, is too fresh in the minds of central station managers to need extended mention, having already opened an office on New Oxford street, London, W. C., England, has now been out West and in Chicago for the past week making arrangements to open a Chicago branch which shall act as a general distributing depot for the entire Western and Central States, except the Pacific slope, which latter will continue as heretofore to be handled by the San Francisco agents.

The company has taken a handsome suite of offices at 1239-1240 the Monadnock Block, to be opened on February 1, under the charge of Mr. Jos. M. Hill, formerly of the Columbia Incandescent Lamp Company, who becomes the Western manager.

A special feature of the offices will be a room devoted to the use of their friends when in the city, a stenographer, typewriter, and files of the newspapers and technical papers being at their disposal. Bryan Marsh Company will be glad to have their friends make their office a rendezvous and headquarters to which mail can be addressed.

A stock of one hundred thousand lamps will be carried, so that all orders may receive prompt attention; such stock will include Candelabra, Baby sign lamps, special series, etc., for which specialties this company is noted as producing the largest variety known.

THE ELECTRICAL EXCHANGE.

The Electrical Exchange, Chicago, have recently removed from their old quarters in the Monadnock Block to much larger offices in the Springer Building, 166-174 South Clinton street. In connection with their former office they had a wareroom at 173 Lake street, but with their rapidly growing business, they found that it was absolutely necessary to have more extensive offices and stockrooms to enable them to carry on their business successfully. In their new premises, which are 125 feet deep, they have about 4,000 square feet of floor space, of which the offices occupy about 1,000 square feet. The store and offices are lighted by electricity and gas, and in the rear there is a small plant for the purpose of doing repair work. The stock will consist as heretofore of new and second-hand apparatus, arc and incandescent lamps, and electrical supplies.

This concern, which commenced business less than a year ago, has already grown to very considerable dimensions, and is a good example of what may be achieved by perseverance and industry; and its members state that they believe that a great deal of their success is due to the fact that they have advertised quite extensively since they opened up for business. In connection with their business the Electrical Exchange issue a monthly bulletin containing a list of goods which they carry in stock. The Exchange was incorporated Nov. 1, 1896. The officers of the company are C. L. Glasner, president; T. S. Leane, secretary and treasurer.

CROCKER-WHEELER MOTORS IN THE NEW ASTOR HOTEL.

Thos. J. Fay and Associates, New York agents and general exporters for the Crocker-Wheeler Electric Company, 143 Liberty street, New York, have been awarded the contract for the ventilating motors to be used in Mr. John Jacob Astor's new hotel, comprising as follows: Two 24 horse-power motors, maximum speed, 190 r. p. m.; one 30 horse-power motor, maximum speed, 140 r. p. m.; one 32 horse-power motor, maximum speed 175 r. p. m.; one 40 horse-power motor, maximum speed 115 r. p. m.; one 60 horse-power motor, maximum speed 175 r. p. m.; one 90 horse-power motor, maximum speed, 140 r. p. m.

These motors will be direct connected to exhausters and blowers and the plant is probably the largest and most complete electrical equipment for ventilating work for which a contract has been let.

SALES OF AMERICAN-BALL APPARATUS.

The following is the list of machinery shipped by the American Engine Company, Bound Brook, N. J., during the month of December, 1896: One 60 horse-power American-Ball engine to the Albany "Journal," one 5 horse-power motor to the Western Newspaper Union, one 100-light dynamo to the Chattanooga "Daily News," one 5 horse-power motor to the Gazette Publishing Company; one 12 horse-power motor to the Toledo "Blade," one 12 horse-power motor to the W. D. Boyce Co., one 9 kilowatt dynamo to the Age Herald Publishing Co., one 9 kilowatt dynamo to the Dayton "Journal," one 3 horse-power motor to the Indianapolis "Sun," one 75 kilowatt dynamo to the Inquirer Co., one 3 horse-power motor to the Harrisburg "Telegram," one 9 kilowatt dynamo to the Jarecki Manufacturing Co., one 100 horse-power motor to the Boston "Herald."

MR. E. G. BERNARD, of the E. G. Bernard Co., Troy, N. Y., has sent out to his friends a tasteful card on which is mounted a thermometer, while the picture at its side does much credit to the Trojan idea of female beauty. Mr. Bernard has now installed 1,200 lighting plants and is ready to do it again.

ADVERTISERS' HINTS

THE INTERIOR CONDUIT AND INSULATION COMPANY, New York, pronounce their celebrated system of wiring ducts to be standard.

K. McLENNAN & CO., Marquette Building, Chicago, Ill., offer some testimonial letters relative to the merits of Gale's commutator compound.

THE ARMORITE INTERIOR CONDUIT COMPANY, Detroit, Mich., publish a price list of Armorite conduits, elbows and couplings.

EDWARD & SHARP, 44 Niagara street, Buffalo, advertises a 15 horse-power, 500 volt motor for $100 and other bargains in electrical apparatus.

THE FOREST CITY ELECTRIC COMPANY, Cleveland, O., are manufacturing a rail bond about which they will furnish any information desired.

MESSRS. WILLIAMS, COUCH & WHITMAN, 196 Summer street, Boston, Mass., advertise telephones for all services.

NEW YORK NOTES

S. K. REYNOLDS, AGENT, Room 626, 136 Liberty street, New York, reports a very satisfactory business. The "self-insulating" cut-out or perfect "bug" put on the market by Mr. Reynolds is meeting with immense success; thousands of them are now being ordered and placed with fixture and supply houses throughout the country, aside from being highly recommended by consulting engineers and others. The "bug" is smaller than any other on the market. Insulation is effected with the connection, therefore requires no cover, it cannot ground the fixture, and tape is unnecessary. It is claimed to be the cheapest device of its kind on the market. Circular and prices will be cheerfully mailed on application.

THE MANHATTAN GENERAL CONSTRUCTION COMPANY have issued a very pretty calendar, in which two beautiful women are shown holding up Manhattan enclosed arc lamps, against a sky whose starry firmament spells out the company's name. The effect is quite pleasing.

THE PURITAN ELECTRIC COMPANY have issued from their New York and Boston offices a very handsome calendar for 1897. The brief reading matter relates to their noiseless arcs for alternating and constant potential circuits. The picture is that of the Puritan forefathers on their way to church through the snowy woods wherein lurk war-painted Indians.

MR. D. G. SCOTT, late of the American Electrical Works, has connected himself with the Bibber-White Company, of Boston, and will take charge of their office and store rooms at 136 Liberty street, New York, where a full line of Crefeld rubber-covered, weather-proof, magnet, annunciator, office and all other wires made by this company will be carried. Mr. Scott is a hustler, and we predict for him and for his company their full share of the business in their line from New York and vicinity.

WESTERN NOTES

THE FARR TELEPHONE AND CONSTRUCTION SUPPLY COMPANY report that their business continues to be very brisk and that they have no reason to complain of the dullness of trade which has been felt for a considerable length of time in nearly all lines of business. Their sales for last year were the best they had since they started in business.

MR. T. C. RAFFERTY, who is probably one of the best known men in the electrical supply business in the West, is now associated with the Metropolitan Electric Company, of Chicago, having disposed of all his other electrical interests. All of Mr. Rafferty's friends and customers will undoubtedly be pleased to learn of his new connection, which will afford him ample scope for his energetic work, enabling him to take care of his customers' wants in a befitting manner, and renew old and pleasant trade relations. We wish him every success in his new work and congratulate the Metropolitan Electric Company on their foresight in securing his services.

ELECTRIC APPLIANCE COMPANY.—In the advertising columns of this issue, the Electrical Appliance Company tell rather an amusing story of the enthusiasm of the contractor over his first job with Armorite conduit. It certainly is a pleasure to a contractor to be able to draw the wire into the tube without the use of soapstone and other lubricants which are usually necessary. The lining of the Armorite tube offers almost no resistance to the passage of the wire, and the wire certainly does slip through the conduit with remarkable ease.

NEW ENGLAND NOTES

BIBBER-WHITE COMPANY, since succeeding to the respective businesses of the New England Electric SupplyCompany and Bibber-White Co., have issued a New Year salutation from their headquarters at 49 Federal street, Boston, and announce that they have swung into line with "the largest stock in the East." They will make immediate shipments and stand ready to quote prices.

PETTINGELL-ANDREWS COMPANY, 72 and 74 Federal street, Boston, compliment us as usual with one of their handsome and effective calendars, the 1897 issue being in every respect worthy of the series. The company are in line for any trade going this year.

ELECTRIC TRANSPORTATION

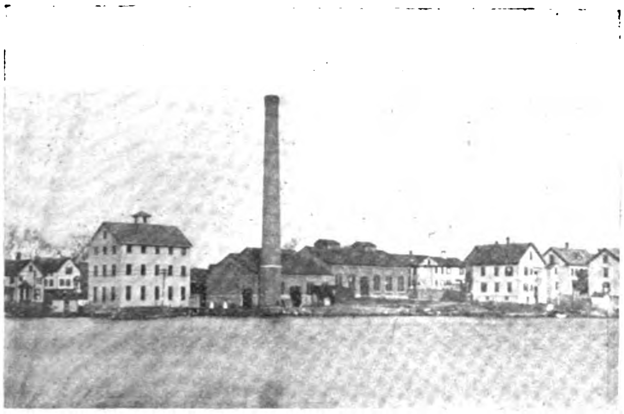
NEW POWER HOUSE OF THE NEW LONDON, CONN., STREET RAILWAY CO.

IN the early part of last winter, the directors of the New London Street Railway Company decided that the time had come when they should, for the more satisfactory and economical operation of the road, have their own power station, having heretofore rented their power from the Oneco Mills. Having reached this decision, they concluded to install a plant capable of handling their business for some years to come, and at the same time one of the highest efficiency, regardless of first cost. Mr. E. H. Kitfield, of Boston, was appointed consulting engineer, and the result is to-day a credit to every one connected with it.

All unnecessary expense for "frills" has been avoided, but the installation has been planned, and carried out in the most complete and substantial manner, for effective and economical operation.

THE POWER HOUSE BUILDING.

The company obtained a plot of ground located on Shaw's Cove, on the Thames River, about 1,200 feet from the nearest point of their road, and centrally located as regards their entire system. Sufficient ground was purchased, in case it should be, at any time, necessary to extend the plant. The plant being located on the water, there is every convenience for condensing.



New London Power House From South Side of Shaw's Cove.

Red brick with local granite underpinning was used for the building, the underpinning being laid in irregular ashlar with a cut granite water table extending all around the building. The roof is of corrugated iron and carried by self supporting steel trusses, and is provided with louvre windows over the engine room and latticed shutters for ventilation over the boiler room.

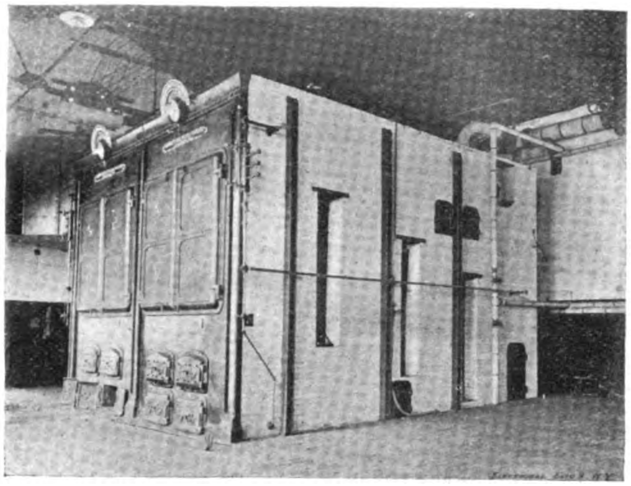
The roof was supplied by the Berlin Iron Bridge Company, and, over the engine room, is lined on the inside with the Berlin patent anti-condensation material, which absorbs the moisture condensing on the under side. The building is one story high and 132 ft. 3 in. in length by 46 ft. in width.

MASONRY WORK.

The engine room is separated from the boiler room by a brick fire wall provided with a single fire door, and an iron stairway leads down into the boiler room. The boiler room floor, and the basement of the engine room are carried through on the same level, while the floor of the engine room is 10 feet higher. This gives sufficient head room and allows easy inspection of the engine foundations, heaters, condensers, piping, and wiring located in the basement.

At the southerly end of the boiler room a brick stack has been erected, octagonal in shape, for about 24 feet from the ground, and running to the height of 125 feet, the upper portion being circular, with an inside diameter of 6 feet.

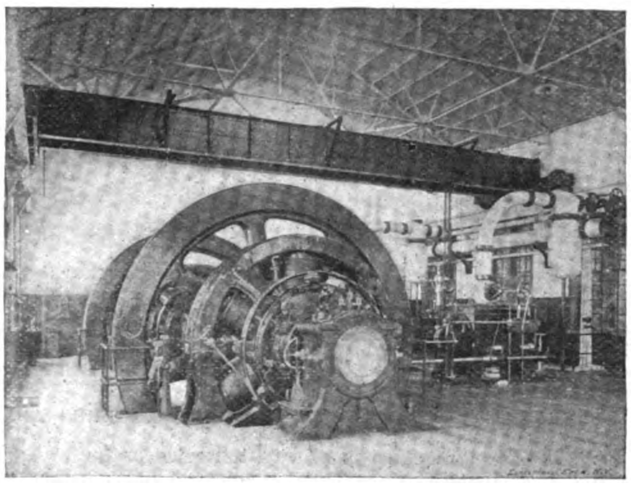
The foundation walls of the building are built of local granite laid in cement mortar, and extra heavy. It was necessary to drive piles for the foundations of the stack and engines, in order to prevent any possible chance of settling. The piles are of oak, cut off at the mean low water level, with two feet of Portland cement concrete for capping. Upon this concrete capping, granite blocks, split to nearly even thickness, and laid in Portland cement mortar, form the foundation of the stack. The engine foundations were laid up with hard burned red brick and Portland cement mortar.



First Battery of Campbell & Zell Boilers.

ENGINES AND DYNAMOS.

The engine room is 69 feet in length by 44 feet in width, and is arranged for three 24-in. by 48-in. improved Greene automatic cut-off engines, manufactured by the Providence Steam Engine Company, of Providence, R. I., speeded to 100 revolutions per minute; the capacity of each engine being 600 horsepower when used condensing, the balance wheels weighing 23 tons. Directly connected to each engine is a 300 kilowatt generator of the latest type, manufactured and installed by the General Electric Company. The switchboard is located at the southern end of the engine room, and consists of two generator panels, and two feeder panels, equipped with the usual G. E. type of circuit-breakers, switches, and lightning arresters, and Weston ammeters and voltmeters. A recording watt-



Engine and Dynamo Room.

meter is also installed on a separate panel, for recording the total output of the station. All the panels are of ornamental slate, supported on iron frames.

In the engine room is located a powerful travelling crane and carriage, the track for which, is supported on steel columns built into the walls of the building. The crane is of a capacity of 10 tons and was one of the first pieces of machinery installed, and was found especially useful in the erection of the rest of the apparatus. This crane was furnished and installed by the Berlin Iron Bridge Company, of East Berlin, Conn.

The floor of the engine room is of spruce planking, upon which is laid the finished flooring of polished maple in narrow strips.

Openings have been left in the floor over the condensers, so that they can be seen distinctly at all times from the engine room. Proper controlling wheels have also been provided on floor stands, so that the principal valves in the basement can be operated without leaving the engine room floor.

The engine room is connected with the superintendent's office in the car house, by telephone.

BOILERS, FEED WATER HEATERS, ECONOMIZERS AND PIPING.

The boiler plant consists of two batteries of improved Zell water tube boilers, of a total capacity of 1,500 horse-power, and were installed by the Campbell & Zell Company, of Baltimore, Md. These boilers were chosen on account of their rapid steaming qualities, and ability to furnish absolutely dry, and slightly superheated steam, at all times, a point of considerably economy in any steam plant.

The floor of the boiler room is laid with hard burned selected brick, laid on edge and grouted with cement, which ensures a smooth and durable surface.

The blow-off piping from the boilers is carried through the boiler room in open trenches below the floor, and covered with cast iron floor plates.

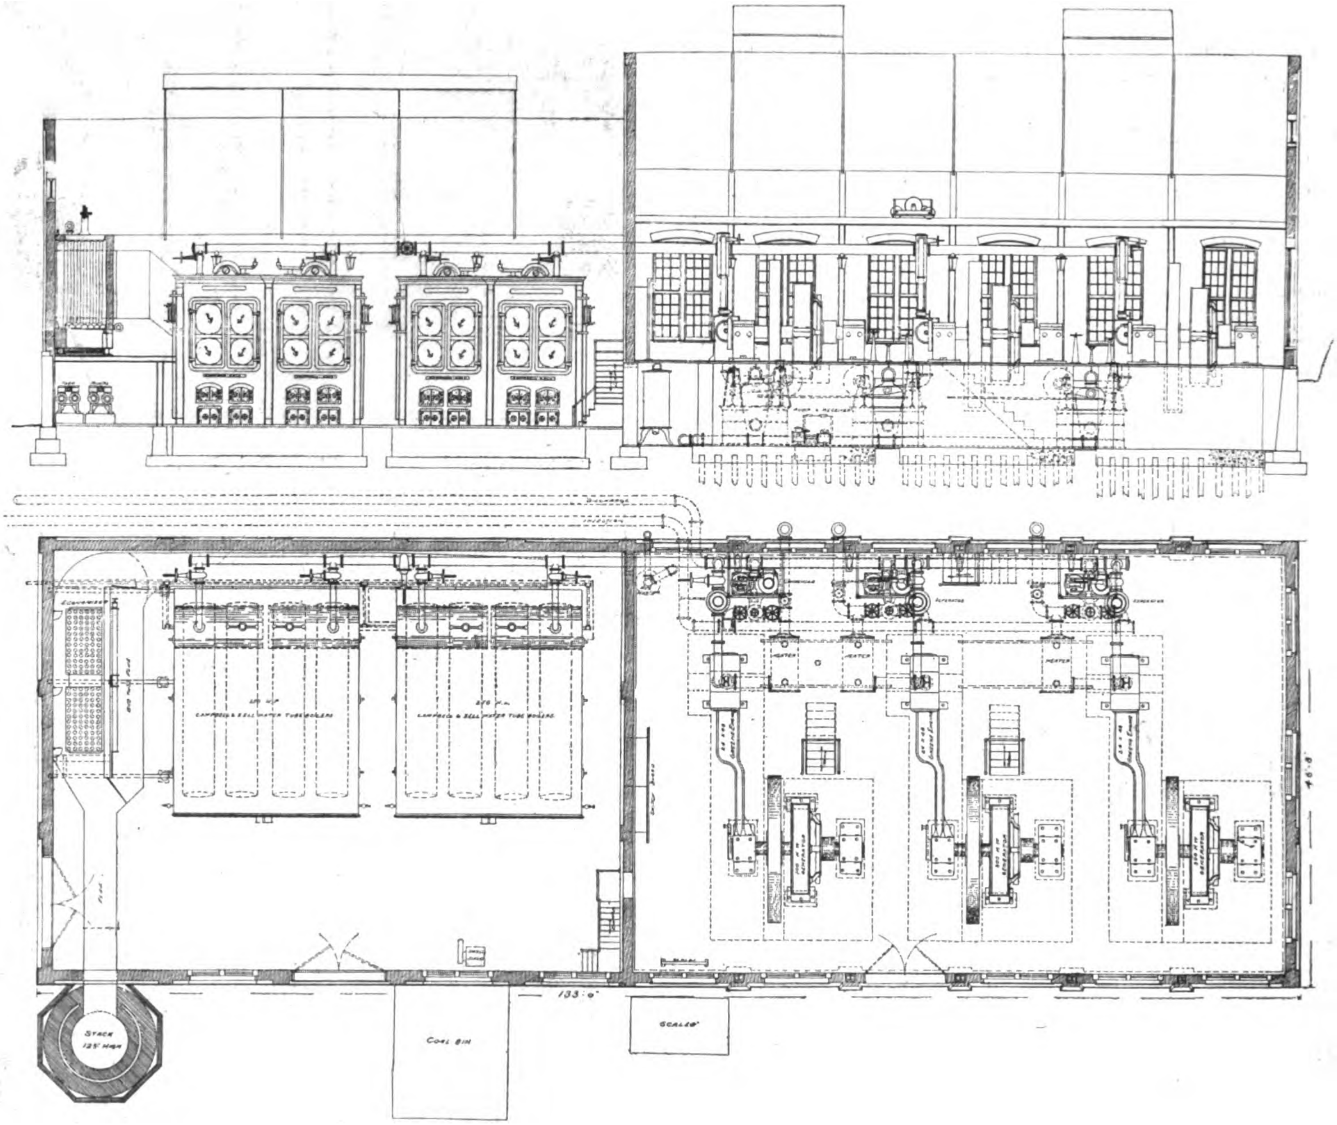
The gases from the boilers pass into the main flue, and then through a Green economizer, before entering the stack. The economizer is supported on steel girders with a head room of 10 feet underneath it, and was installed by The Fuel Economizer Company, of Matteawan, N. Y. A by-pass flue is provided so that the economizer can be cut out, if necessary, at any time.

The draft is controlled automatically by a Spencer damper regulator.

In the space underneath the economizer, the various pumps and meters are located. They consist of two Knowles duplex feed pumps, 5½-in. x 3½-in. x 6-in. stroke, two No. 10 injectors of the Körting type, and two Thomson water meters.

All feed piping and fittings from the main heaters of the boilers are of extra heavy brass. The feed water can be obtained from three independent sources, and by the arrangement of the pumps and injectors and their connections, no accident can possibly cut off the supply of water from the boilers. The feed water entering the building from these various sources, passes through the main heaters, where it is raised to a temperature of about 200° Fahr. by the exhaust steam from the engines; it then passes through an auxiliary heater (through which is carried the exhaust from the condensers and pumps), where the temperature is further raised; it is then passed through the economizer, where the temperature is again increased by the waste gases from the flue, until it finally enters the boilers at about 360° Fahr. The piping is so arranged that, were the entire system of heaters disabled, the water could be fed directly into the boiler.

The fuel is weighed on its arrival at the plant, on a platform connected with a set of Howe railroad scales, and is then shot



The New London, Conn., Electric Railway Power House. Plan and Sectional Elevation.

into a coal shed adjoining and alongside the boiler room doors.

Connected to each engine and placed in the basement under the engine room is a National feed water heater, manufactured by the National Pipe Bending Co., of New Haven, Conn. The condensers are of the Knowles vertical independent steam driven type, 12-in. stroke with one 10-in. steam and two 20-in. air cylinders, and the exhaust from the heaters can be led either into the condenser, or discharged directly into the atmosphere through the medium of an automatic relief valve. By this arrangement each engine is entirely independent, and can be operated condensing, or non-condensing, at will. The condensing water is taken directly from Shaw's Cove, in front of the station, into which it is discharged after using. The average temperature of this water is under 60° Fahr. and it has not to be lifted to any height, these two conditions being verey favorable for economical operation.

All the condensation water from the main steam pipes is returned to the boilers by gravity. Other water of condensation which will not flow to the boilers by gravity, is collected into a receiver, and forced into the boilers by an automatic pump.

The piping of this station is of special interest, and is arranged in the most complete, and yet simple, manner. The main steam piping is extra heavy wrought iron, and all fittings of extra heavy flanged cast iron of the best quality. It is supported on cast iron brackets fitted with expansion rollers, the brackets being securely bolted to the side walls of the building. All main valves are of Chapman heavy duty flanged type with outside screw and yoke, and by-pass. All connections with the boilers and engines are made with brazed copper bends and independent gate valves. Attached to the connecting pipe of each engine, is a Stratton separator, which collects all water of condensation, or possible overflow from the boilers, and prevents it from passing into the cylinders of the engines.

The complete system of piping was installed by W. H. Gallison, of Boston, and is covered with magneso-asbestos covering manufactured by the H. W. Johns Company.

ROLLING STOCK AND LINE CONSTRUCTION.

The company operates from 15 to 20 cars in summer, although a smaller number answers the requirements of the winter traffic. The road is 7.18 miles long, of single track with necessary turnouts, laid with 50 lb. "T" rail. Three-quarters of a mile is laid in paved streets, being supported on chairs; the balance being on macadamized streets, is spiked directly to the ties.

A line of five No. 000 feeders is led from the station to the different sections of the overhead line, while the track circuit is connected to the negative bus of the switchboard by four wires of similar size. A feeder of 400,000 c. m. capacity on the same poles with the overhead feeders follows the line of the rails and is connected to them at intervals of 1,000 to 1,500 feet; the rails in addition, being double bonded so that a very complete and even distribution of the current is the result.

The station was built under the supervision of Mr. E. J. Richards, representing E. H. Kitfield, the consulting engineer of the plant. The excavation and foundation work was done by Mr. George Prest, of New London, and Mr. W. A. Dean, of New London was the contractor for the building and stack, above the foundations.

The plant is under charge of Mr. E. W. Havens, as chief engineer, with Mr. A. Crocker as assistant and James Latham and Andrew Stewart firemen.

The officers of the road are Walter Learned, president; W. A. Tucker, treasurer, and L. Bentley, superintendent; and under their able management the road in four years has become a very valuable property.

PROPOSED MUNICIPAL OWNERSHIP OF STREET RAILWAYS.

Senator McNulty has introduced in the New York State Senate three bills, carrying out the ideas of Edward M. Grout, of Brooklyn, as expressed at a hearing before the Greater New York Commission, regarding municipal ownership and disposal of public franchises. The first bill provides as follows:

"Any city of the first class may establish, construct, or acquire by condemnation proceedings, under the provisions of the Condemnation law, street railroads within its boundaries, whether operated on or below or above the surface of the street, and may issue bonds therefor, and may conduct, manage and operate such railroads by means of its Department of City Works, or other like department, under the supervision of its Common Council, or other legislative bodies."

The second bill provides: "Hereafter no franchise or right to use the streets, avenues, parkways, or highways of any city of the first class shall be granted to any person or corporation for a longer period than twenty-five years; nor shall the same be so granted for less than the best possible terms obtainable therefor, and the action of all officials of cities of the first class in relation to the granting of such franchises shall be reviewable in the courts."

The third bill provides: "Any city of the first class may establish, construct, or acquire by condemnation proceedings under the provisions of the Condemnation law, a plant for lighting by gas or electricity its streets and public buildings and for supplying such light to its inhabitants, and may issue bonds therefor, and may conduct, manage and operate such lighting works by means of its Department of City Works or other like department, under supervision of its Common Council or other legislative body."

INSTITUTE DISCUSSION ON HORSELESS VEHICLES.

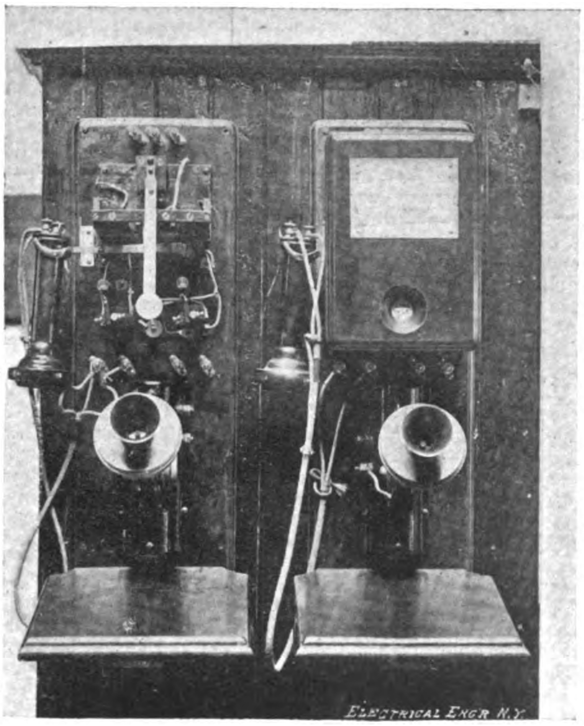
In spite of the extreme inclemency of the weather, there was a fair muster of members of the American Institute of Electrical Engineers at the up-town headquarters on Wednesday night, January 20, to discuss the topic of "Horseless Vehicles." No regular paper was presented, but the discussion was opened by Mr. A. L. Riker, who has done so much good pioneer work in this field, and who now stated briefly the condition of things. He insisted chiefly on the need for great improvement in the storage batteries used. They were built for lighting and other "quiet "uses, but a stronger type was needed for motorcycles. President Duncan also dwelt on the battery limitations and their effect on the travel and speed of the vehicles. Mr. Reckenzaun held that the difficulties to overcome were so great that storage batteries must "take a back seat" for the present. Mr. Adams said that the Electric Carriage & Wagon Company had a carriage that would go 35 miles on one charge. It had made over 1,000 miles without a single accident. It took 20 or 30 amperes at 9 or 10 miles an hour, the battery weighing about 800 pounds. Mr. H. B. Coho related some dismal experiences with storage battery cars that had to be helped home, and suggested the need of carrying a meter that would tell the driver when his current was running short. Mr. Corson said he had seen such a meter in use indicating the point of exhaustion. Mr. Joseph Sachs made an able presentation of the other important features pertaining to motorcycles outside the motor and the battery, such as brakes, wheels, structural material, steering, control, etc. Mr. Riker stated that he was building a carriage with 36-inch rear wheels and 32-inch front wheels, to make 40 miles an hour if need be. It would weigh about 1,400 pounds. He was trying a device like the back gear on a lathe so as to run with due economy on a grade or in overcoming obstacles. He emphasized the importance of simple and effective steering gear. In reply to a question from Mr. Coho, he said that under normal weather conditions he found Belgian block and asphalt to be about equal and slightly better than a good macadamized road. Wooden wheels with plain radial spokes were bad, as the strain always twisted them to pieces. The metal wheels with tangential spokes of wire, and pneumatic tires were preferable. Mr. Sachs having cited other powers, and the Serpollet boiler, Mr. Riker stated that the Count de Dion, who had done so much with other forms of vehicles, was now working on an electric carriage. As to a single motor, it was better than two on the grounds of less cost, greater efficiency and diminished weight. Mr. Van Hoevenbergh made a happy little speech in which he suggested horseless vehicles not running on tracks, but taking current from overhead wires by means of extensible trolleys. Mr. Duryea, the well known builder of gasoline carriages, expressed an opinion against putting the mechanism on the trucks or axles. He defended gasoline vehicles on various points. Even the smell, which was less objectionable than that of the horse was now being rectified, and in any event it was behind the passengers instead of in front of them. The trouble with electricity was its difficulty and slowness of resupply. Gasoline could be picked up almost anywhere and a little went a long way. The great goal and desideratum for a horseless vehicle was light weight, which the electric carriage did not give. Mr. Riker replied to some of these points, and went on to criticise, the storage battery again, although expecting great improvements. He had tried that day an excellent cell which had charged up in 3½ hours and discharged in 2¾ with an efficiency of 65 per cent. The discussion, which lasted until after 10 p. m., was brought to a close with some felicitous remarks from secretary Pope, who pointed out some fields of usefulness and commented on the present cost of handling goods in transit through or about cities.

TELEPHONY AND TELEGRAPHY

RECENT IMPROVEMENTS IN PARTY LINE TELEPHONE SYSTEMS.

THE desirability of obtaining a satisfactory party line system or one in which more than one subscriber's telephone may be connected to the same metallic circuit, has long been recognized by telephone companies, and has resulted in considerable study and experiments. Many systems, each more or less workable, have been prepared and some of these are now in operation. Few, however, have realized the full economy that should result from the increased earning capacity of a circuit without detriment to the subscribers' service. It is evident that no system, though permitting a reduction in rates, would be generally acceptable to the subscriber if accompanied by a loss of privacy in conversation and the annoyance of having his bell rung when another on his line was being called.

A satisfactory system would, with all the economy of a party line system, give to the subscriber all the advantages of a private line. A system fulfilling these conditions to a high degree has recently been brought out by the American Telephone and Telegraph Company (long distance). Without attempting a detailed description of the central office equipment or the mechanism of the subscribers' telephone sets, the system may be described as follows: The switchboards in the exchange differ but little in general appearance and method of operation from ordinary telephone switchboards. Each line terminates in its springjack and corresponding line drop. Each operator's position is equipped with the usual number of pairs of cords and plugs, with their corresponding listening cams and clearing-out drops. Instead, however, of a pair of ringing keys for each pair of cords, there are in the party line boards a single group of ringing push bottons, a "locking" and an "unlocking" button for each operator's position. By depressing its corresponding listening cam, these push buttons may be cut in upon either the calling plug, or by also depressing a shifting cam upon the answering plug of any pair. The push buttons are so wired to a battery in the central office that each, upon being depressed, forms a particular relation between the battery terminals, the ground, and the two wires of the metallic circuit, terminating in the springjack to which the active plug may be connected; each push button giving a current combination different for all the others.



PARTY LINE INSTRUMENT OF THE LONG DISTANCE TELEPHONE CO.

The subscriber's telephone apparatus also has the usual outward appearance, as shown in the accompanying engraving. The difference lies mainly in the small box above the transmitter which usually contains a magneto hand generator and a polarized bell, but which in the party line apparatus conceals a few simple devices. One, slightly different in each of the stations on the line, controls the subscriber's telephone bell and responds only to the current combination furnished by its corresponding ringing push button, thus enabling the operator to ring up any subscriber without ringing the telephone bell of any other on the same line.

Another device having its counterpart in each subscriber's telephone apparatus responds to currents from the locking and unlocking buttons, enabling the operator by depressing the former to lock out, that is, cut off all the subscribers on the circuit from access to it, preventing them from listening to, or interrupting, the conversation of any subscriber to whom the operator may release the line, and by depressing the latter button to unlock, that is, give all subscribers access to the line. A third device furnishes the operator with the means of unlocking the telephone of the subscriber she rings, without unlocking any other on the line; and still another device whereby the subscriber may call central.

On the front of the box cover is a plainly printed card giving the subscriber a few simple directions in regard to the use of his telephone and below the card a small circular window, behind which a signal actuated by the locking mechanism appears when a subscriber is using the line, informing each subscriber on the circuit that the line is in use.

A subscriber desiring to call central—the "line in use" signal not being in view—does so by simply removing the telephone receiver from its hook. This act sends an impulse of current over the line throwing the line drop in the switchboard. The operator seeing it fall, immediately connects her talking set to the subscriber's line jack with an answering plug and cord and listening cam, locks out the other subscribers on the line by depressing the locking button and takes the subscriber's order.

If the subscriber desires to converse with one on another party line, the operator connects the two lines together through a pair of cords, and through trunking circuits, if necessary, locks out all subscribers on the line and depresses a ringing button corresponding to the telephone of the subscriber wanted. This sends a current combination out over the line which, without affecting the locked condition of the telephones of the others, or ringing their bells, rings, and at the same line unlocks the telephone of the subscriber wanted. The desired subscriber having answered the call, the two on different party lines can converse with the same degree of secrecy as though each had a private line.

Upon finishing their conversation, each hangs up his receiver. This sends current impulses over their lines and gives the operator the disconnect signal. Seeing it, she assures herself that the conversation is ended and then depresses the unlocking button, sending current out over both lines in the proper manner to unlock the instruments of all the subscribers on both.

If he desires it, the operator may connect a subscriber with a party on his own line, or she may, through the medium of trunking circuits give him connection with any local or long distance points operated on any telephone system.

OPPOSITION TELEPHONE EXCHANGES WEST.

A special dispatch of January 19 from Fort Wayne, Ind., says: To-day 43 representatives of independent telephone companies of Indiana met in this city for the purpose of discussing the advisability of forming a State organization to compete with the Bell Telephone Company. Charles McCulloch welcomed the delegates to Fort Wayne. Judge R. S. Taylor followed with an address. Mr. Taylor is principal counsel for the Government in the Berliner patent cases, and he was subjected to many questions. E. H. Andress of Lafayette, president of the Indiana Mutual Association, presided. There was a general sentiment in favor of some united system, but it was determined to first secure legislation which would protect the independent companies against the Central Union. An executive committee was appointed as follows: W. J. Hazey, Fort Wayne, chairman; L. A. Frazee, Connersville; E. C. Bickel, Elkhart; Charles S. King, Wabash; John D. Pugh, Shelbyville; Jasper A. Gauntt, Marion; J. L. Stone, Rushville; C. A.

Reeve, Plymouth, and E. H. Andress, Lafayette. Judge James N. Thomas, of Chillicothe, O., president of the Ohio Independent Telephone Association, invited the Indiana delegates to attend their State meeting at Columbus January 26. An effort will there be made to form a company in the States of Indiana, Ohio and Illinois.

THE PACIFIC CABLE PROJECT.

A dispatch of Jan. 22 from Washington says: James A. Scrymser and Edmund L. Bayliss were before the House Committee on Interstate and Foreign Commerce to-day in the interest of the Pacific Cable Company of New York. They both argued upon the merits of the Scrymser bill over the Spalding bill of the New Jersey Company. Mr. Scrymser stated that his company would want eighteen months after the passage of the bill to complete the cable to Hawaii and one year more to complete it to Japan. In case of war with England cable communication with Europe would be cut off by this plan. Mr Patterson (Dem., Tenn.), said that it had been charged that the Scrymser company was in sympathy with or had connection with England and English interests. Mr. Scrymser said that of course his company would expect to do English business. Mr. Patterson said that there should be inserted in the bill a provision that the cable company should not come under British influence.

Mr. Scrymser referred to the statement that Japan wanted no other cable connection as ridiculous. The Spalding company, he said, would build to Hawaii and stop. His line to Japan would save the people of that country more than a million dollars in tolls. "The Japanese," he said "are flocking into Hawaii now. This country is going to have a contest with the Japanese or some other power to control Hawaii. It is necessary to have a cable line there as soon as possible."

Mr. Scrymser did not like the idea of leaving the matter of contract with the Postmaster-General. "The present Postmaster-General will not have time to act, and we don't know who the next Postmaster-General is or what he will do," he said.

The discussion among members of the committee developed that there is yet a wide difference of opinion on the subject of the cable.

TELEPHONE RATES IN NEW YORK STATE.

In the State Assembly Mr. Cain has introduced a bill regulating telephone charges so that New York subscribers shall pay a rental of $85 per annum, Brooklyn $75 per annum, cities of less than 500,000 and more than 100,000, $48 per annum; cities of less than 100,000 and more than 20,000, $36 per annum; cities of less than 20,000 and more than 8,000, $30 per annum, and all cities and places of less than 8,000 inhabitants, $27 per annum. The pay station tolls are to be 10 cents for the first five minutes' conversation and 5 cents for every five minutes thereafter. The measure also provides that the Controller, Attorney General, State Engineer and Surveyor shall constitute a board to examine and regulate the affairs of telephone corporations, and that they shall be recompensed for all moneys paid for clerical assistance.

JERSEY COAST TELEPHONE LINE.

It is now possible for Division Inspector Holland, of the New Jersey Life Saving Service, to talk by telephone from his office at Point Pleasant, a few miles south of Sandy Hook Light, to the life saving crew on duty at the station on Cape May Point, a distance of nearly 200 miles. The line has been partially operated for several years, but was not made complete until recently, because of the failure of the government linemen to sink cables successfully beneath the inlets along the coast, some of which, Great Egg Harbor, for instance, are quite wide.

Finally, all obstacles were overcome, and the system made complete. All of the stations on the coast are now connected, and the life saving service will be benefited greatly thereby. The Atlantic City station has been made the central office of the coast system.

PUNISHING TELEPHONE TRICKSTERS.

A MOVEMENT has been set on foot in Missouri to secure additional legislation at the coming session of the State Legislature to correct some of the abuses of the telephone system. It is well known that the business and professional men of St. Louis are frequently made the dupes of telephone pranks perpetrated by unknown persons, or the victims of schemes of irresponsible parties who use the telephone in carrying out their work. At present there is no system whereby the culprits can be detected, and the present movement is to secure legislation to that end.

There is a law in Missouri making it a crime to send false messages over the telephone or telegraph wires. Several convictions have been secured under the statute, which is known as section 2728 of the Revised Statutes of Missouri. It reads:

"If any officer, manager, agent or operator of any telephone or telegraph line operating in this city, or any other person, shall knowingly transmit by such telephone or telegraph line any false communication or intelligence with intent to injure any one or to speculate in any article of merchandise, commerce or trade, or with intent that another may do so, or shall knowingly send or deliver any dispatch that is forged or not authorized by the person whose name purports to be signed thereto, shall, on conviction thereof in the court having criminal jurisdiction in the proper county, be liable to the same penalty as provided in section 2725."

The section referred to makes the penalty $200 for every offense. A conviction was had in St. Louis under the law several years ago, when a hackman was fined $20 for sending a false message to a rival. The victim of the trick had his cab stationed at the most advantageous point at a public stand. His rival went to a near-by telephone and sent in a call for a vehicle. The victim was told that his cab was wanted at a point about three miles away. After he had driven off his rival took his place. When the man found out the hoax he complained to the telephone company, and an investigation was made. It so happened that the subscriber of the telephone from which the "fake" cab call had been sent remembered the occurrence, and a warrant was issued against the culprit, and he was fined $20. It is safe to presume that he never sent any more "fake" messages.

One of the remedies suggested for the abuses of the telephone and telegraph system is to make the penalties on a line with the postal laws, which are very strict, and which summarily deal with tricksters. Another suggestion is to inaugurate a system of checking all telephone calls from public telephones. In this way a line could be kept on all messages, as the subscribers of private service would be held to account for messages sent from their boxes.

Many physicians can tell of hurried trips they have made in response to urgent calls over the telephone, only to find that the number given was a vacant house or an empty lot. The police every now and then are summoned on "fake" riot calls, lawyers are sometimes called away from their work on "fake" appointments, and there is hardly a large business house in St. Louis which has not been victimized by sharpers or "jesters."

Several years ago a man went to a lumber office on Clark avenue, St. Louis, and telephoned to fifteen undertakers in rotation, notifying them that a certain well-known citizen in the West End had died, and that the body should be embalmed at once and removed to the undertaking rooms. In less than an hour there were fifteen undertakers' wagons at the number given, but each undertaker, in turn, found his supposed subject a very lively corpse, and mad as a hornet. The excitement in the neighborhood was intense. The undertakers departed, but before doing so they held an indignation meeting on the street corner and decided to investigate the matter. The telephone company was notified, and an investigation was begun. It happened that the operator remembered that a certain telephone box had called up nearly every livery stable in town, and with that as a starter the matter was traced to the man who did the telephoning. For some reason or other, however, there was no prosecution, although the telephone company was anxious to make an example of the fellow.

NO MENTAL DISTRESS DAMAGES FOR A DELAYED TELEGRAM.

Among the decisions handed down by the Appellate Division of the New York Supreme Court last week was one in the case of Curtin vs. The Western Union Telegraph Company, in which the Court holds that there can be no recovery on account of mental distress occasioned by the failure to properly transmit and deliver a telegram. In this particular case there was such a delay in the delivery of a dispatch announcing the death of the plaintiff's brother that she was unable to attend his funeral. The precise question has been determined the same way in other States, and yet the view that damages ought to be recoverable under such circumstances has been earnestly maintained by some law writers and judges. Messrs. Shearman and Redfield in their well known treatise on the law of negligence say on this subject: "Delay in the announcement of a death, an arrival, the straying or recovery of a child, and the like may often be productive of an injury to the feelings, which cannot easily be estimated in money, but for which a jury should be at liberty to award fair damages." The authors cite a Texas decision, however, as authority for the proposition that the receiver of a telegram is not entitled to recover damages for mental suffering alone.

MISCELLANEOUS

ELECTRICITY IN NAVAL LIFE.—XV.

(Concluded.)

BY LIEUT. B. A. FISKE, U. S. N.

DIRECTION OF FUTURE PROGRESS.

IT would require an inspired prophet to foretell this exactly, but it would require only a man of observation to predict certain phases of it within a small probability of error.

At the present time in various branches of engineering we see the use of electrical appliances gaining so rapidly on hydraulic and pneumatic appliances and on auxiliary steam apparatus, that he must shut his eyes and close his ears very tightly who cannot see and hear the approaching triumph of electricity. Can we then not feel it as an absolute certainty that electric power will soon be used in all our warships—and merchant ships also—for auxiliary engines? There is a predilection in the minds of a few officers in favor of hydraulic apparatus; and many officers like steam. Doubtless there may be some who prefer pneumatic apparatus, but they are few in number and hard to find. The only important difference of opinion, therefore, seems to be between steam and electricity; because steam has the undeniable advantage of saving weight and space and money; but how there can be any question between the relative advantages of electricity and hydraulics, it is difficult to imagine. Whatever faults electric power on shipboard has (such as the necessity for a generating plant, the increase of parts, etc.), hydraulics has in at least an equal degree. And it may be iterated and reiterated that every advantage which hydraulics possesses, electricity possesses in an equal degree; and for every disadvantage which electric power possesses, hydraulics possesses another at least equally great. Yet electricity possesses many advantages which hydraulics does not possess, and hydraulics has many disadvantages which electricity has not. The whole trend of engineering professions is away from hydraulics and towards electricity. This is true even in ship work, for many people now understand what it means to keep valves and joints from leaking under high pressure, and recall the fact that in the Maine and the Benbow the water simply froze everything stiff and tight, and put the ships absolutely hors de combat.

The electrical arts are certainly younger than the hydraulic arts, and yet it is time to cease to regard electricity as a species of illusion or humbug, and to cease to look on an electrician as a species of fakir or magician. As a matter of fact, in all the colleges and electric companies of the country we find men of the highest order of intellect and education engaged in the study of electricity from both a scientific and an engineering standpoint, and the amount of money invested in it is many times greater than that invested in all our ships put together.

So, in deciding between hydraulics and electricity for auxiliaries in ships let us not be blind to the fact that if we decide in favor of hydraulics, we shall take a step backward as judged from engineering progress broadly considered, and place ourselves in the position of the only sensible juryman out of twelve.

Let us hope that we soon shall see a civilized modern ship, in which there shall be a fine large dynamo room, like those under the great New York hotels, where power will be generated for lighting the ship, making the signals, hoisting the ammunition, turning the turrets, operating the telephones, hoisting the boats, ringing the bells, weighing the anchor, sounding the alarms, running the launches, firing the guns, steering the ship, etc. And why should we not have a neat electric galley, such as are frequent in New York, where the meals of all can be prepared in cleanliness and quiet, with only a fraction of the fuss and confusion now attending the getting of the food and the coal and the heating of the water? And why should not both officers and men, when they go on night watch, frequently in the wet and rain, be given a light repast, cooked on an electric stove, the size of a quart pot? Would the lookouts, or the quartermasters, or the officers, do their duty any less vigilantly if each had half a pint of hot coffee and a piece of nicely browned toast in his stomach? But whatever will be the exact paths that electrical progress will pursue, it is unquestionable that it will strengthen the hands of the commander and give him better control of his forces both material and personal. This does not mean that a commander—either of a fleet or ship—will be expected to attend to all matters from the conning-tower, because that would overwhelm and overpower him with details which had better be left to subordinates; but it means that he shall be instantly informed of everything that happens, and that he shall be able instantly to give such instructions as he shall think best; it means, in other words, that he shall be able to direct affairs instead of being helplessly directed by them. The real end and aim of discipline is not to put men in the brig or to make them touch their caps, but to give a commander control of the forces under his command, some of which are at a distance. And above and beyond all questions of comfort, and of routine, and of detail, and of beauty, and of the nature of auxiliary engines, and of etiquette, is the question of the control of the ships, and of the various factors, offensive, defensive and directional, which give the ships their fighting value both singly and when combined in squadron. This means that signaling in its broadest sense—signaling both among the parts of a ship and among the ships of a fleet—must be improved, and then improved again and again, with never a rest in the onward march.

SIGNALING AT SEA.

The electrician and the inventor recoil in despair before the difficulties which this problem presents. Guns, armor, hulls and engines change from year to year, but when we wish to signal by day we do the same things that Nelson did at a time when electricity and steam were almost unknown outside the "Proceedings" of scientific societies. Yet there must be a way to signal across the water; the question is, "Where is the way?" If we can talk with ease from New York to Chicago, over a distance of 1,000 miles; if we can telegraph over the same line 200 words a minute and receive the message printed on a page; if we can photograph the interior of the body of a living animal; if we can telegraph under all the oceans, and send news to and from all quarters of the world—why—why—can we not signal half a mile over the water from ship to ship?

The solution of the problem lies probably in the direction of electric induction, the transmitters and receivers being so constructed, and so adjusted relatively to each other in resistance, inductance and capacity, that they will be in sympathy, or resonance, with each other, in which condition the receivers will be at their maximum sensitiveness to vibrations propagated from the transmitter.

Many experimenters have attacked this problem, but each, in turn, has been put to rout, "horse, foot and dragoons." Among others, the writer in 1887 essayed his feeble powers, both at the New York Navy Yard and the Stevens Institute. In one experiment he used the U. S. S. Atlanta as the transmitter and the U. S. tug Nina as the receiver, wrapping them horizontally with many turns of wire. The Atlanta's wire was coarse and traversed by the dynamo current; while the Nina's wire was fine and in circuit with two telephones. The Atlanta then formed the largest electro-magnet ever constructed, and she still holds the record; but the experiment, like all the others, was a failure in a practical sense, though signals were transmitted over, say, a hundred feet. On other occasions, the writer, amplifying some experiments of Prof. A. Graham Bell, signaled by means of electric currents propagated through the water. Fairly good signals were sent a hundred yards, but they could not be induced to go any farther. It is to be said, however, that all these experiments in signaling were conducted by the various experimentrs in a desultory fashion, and before the laws of electrical sympathy or resonance were well understood. And it is the belief of the writer that, if some competent person were given proper facilities by the government, or by private parties, he could develop a system of signaling which would be equally good by day or by night, in clear weather or in fogs. Until then we shall have to be as happy as we can with the Ardois system and electric wig-wags; unless some good magician, with a wave of his wand, will bring into being some simple and beautiful discovery or invention, the like to which we do not dream of now.

CENTRAL STATIONS.

The problem of insuring rapid and sure communication among the various compartments of a warship has brought about the same solution as a similar problem has brought about in modern cities—a "central station"; and the more the subject is considered, the more plain it becomes that a central station is the only thinkable solution in a city, a large building, or a ship. And not only this, but in a warship the solution is the more complete, because, added to all other conditions of the problem, is the important one that the means of communication and the operators must be as much protected as possible. It is an admitted fact that the problem of where to put the conning-tower and how to arrange it has not yet been solved, but the central station below the water-line comes pretty near solving it, because much, if not all, of the complicated apparatus heretofore put in the conning-tower can now go in the central station, and the captain needs only a telephone or large speaking-tube connecting him with his aide in the central station. The conning-tower being thus relieved of most of its apparatus, can be made smaller, and for a given weight, covered with thicker armor, so that it will be extremely hard to hit and almost impossible to destroy.

It has been proved in service that speaking-tube communication, or even telephone communication, is very inefficient between the conning-tower and those parts of the ship, such as the battery, turrets, engines, etc., in which there is much noise; and that it is utterly useless for communicating simultaneously with several persons under the conditions of action or even general quarters. But telephonic communication can be made perfectly satisfactory betweeen two people, one in the conning-tower and the other in the central station; because a central station can be made quiet, and because the two people, say the captain and his aide, can keep their telephone receivers on their heads all the time and become accustomed to each other's voices and modes of intonation. Then from the central station reach out the various visual signals for silently telegraphing ranges, battle orders, directions to the helm, engines, etc.; and there is received news from all parts of the ship for transmission to the captain. The central station should be as near the conning-tower as possible, for obvious reasons; but even if in some ships it should have to be at some distance, yet the telephone will put matters in the same condition as if the captain and his aide were absolutely in the conning-tower together and holding verbal communication. Aside from the value of protection for all the interior signaling apparatus, both for sending and receiving, the advantage of having all the operators in a quiet place, where they will be as free as possible from exciting and disturbing causes is clearly of paramount importance.

It is to be hoped that the tremendous advantages to be derived from a central station properly situated and equipped will be more and more fully recognized, and that in the original designs of our new ships the central stations will be really properly situated and equipped. It would seem that the principle governing the arrangement of electric apparatus in ships should hereafter be the same as in large establishments on shore, viz., that all apparatus which is delicate, or which requires great skill in its operation, should be confined to the central station, and that the apparatus placed elsewhere should be of the simplest character as regards both its construction and its manipulation.

If this plan were adopted, we could get rid of the armored tube with its multiplicity of chains and wires, a blow on which from a heavy shell would paralyze all means of communication and leave the captain helpless. We might even get rid of the conning-tower itself, because all that would be needed would be a strong steel post, or bar, behind which the captain could stand, like a sharpshooter behind a tree; with perhaps a quartermaster near him, to direct the helmsman in the central station.

It is now proposed that the executive officer shall be stationed in the central station in action, in order that, if called upon to take the captain's place, he shall be au courant of what is going on. If this be done, why should not the executive officer be the gunnery officer of the ship, and charged especially with the matters relating to her fighting efficiency, her guns, turrets, electrical mechanism, etc? Then he would, if called on to assume command of the fighting machine, do so with an intimate knowledge of all her fighting factors, instead of with an intimate knowledge of liberty lists. But, as Rudyard Kipling would say, "That is another story."

THE MAKING OF ELECTROZONE IN PHILADELPHIA.

Dr. William H. Ford, president of the Philadelphia Board of Health, in speaking of the action of the Building Commissioners in prohibiting the manufacture of electrozone in the basement of the city hall, said the commissioners were led to take that action because some of the fluid, which had been left in a tank through the mistake of an employé, accidentally leaked out and ran over the electrical wires, eating away the insulation, and, when they made an investigation, they learned that some of the electric power was utilized in making the disinfectant.

"We can manufacture electrozone there ourselves at a very light cost," he said, "and as it is an absolute necessity, it would save the city thousands of dollars were we allowed to continue. The disinfectant is very necessary to the health of the city during the warm weather, the only time we manufacture it. It is in liquid form, and is placed in the gutters, inlets and other places from which bad and dangerous odors emanate and from which many disease germs come. It neutralizes the odors and destroys the germs. If we are compelled to purchase it from manufacturers it will cost us fully double what it is costing us now. I think it is probable that the order will be rescinded."

UNIPOLAR MACHINES AND THE "CUTTING LINES OF FORCE" THEORY.

BY PROF. W. A. ANTHONY.

In your issue of January 20, page 79, is described "Another Unipolar Machine That Will Not Work," and the author's claim that the theory of "cutting lines of force" fails to explain why.

Referring to their figures, illustration, Fig. 1, all the lines of force, according to the theory, go across the space from the pole, S, to the pole, N, through the core, A. The wire passing through the hole, B, in the core, must, therefore, cut those lines just as much as the wires on the surface of the core.

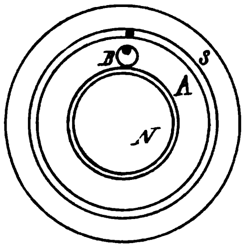


FIG. I.

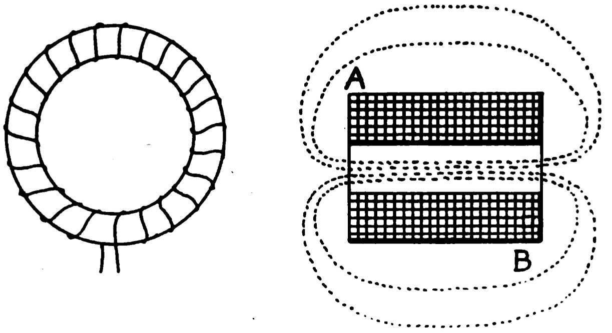
There being the same number of wires through the holes as on the outside of the core, the E. M. F.s developed would exactly neutralize each other and the result obtained by the experimenters should have been expected. Indeed, this scheme for cheating the magnetic field was proposed to the writer some ten years ago, and he then pointed out the fallacy by reference to the "theory of cutting lines of force."

If a single wire, either on the outer surface of the core, or through the hole, B, were connected at the two ends to sliding ring contacts, a difference of potential would be found between those rings when the armature was rotated, and this difference of potential would be the same in amount and direction whichever wire was used.

This is what the line cutting theory teaches, and is what experiment would prove.

While I am upon this subject I wish to refer to another case that often turns up as a stumbling block. In the simple transformer, in which the magnetic circuit is a closed circuit, all iron, as in the sketch, Fig. 2, it is often stated that there can be no cutting of lines of force where the current is reversed.



FIGS. 2 AND 3.

But it must be remembered that by the theory the lines of force are always closed curves. They are never broken and never present any loose ends. When a current flows through the wire around the iron core in the figure, no one doubts that lines of force exist in the core and form closed curves. If the current be broken those lines of force disappear.

What becomes of them? How do they get out of the core? They cannot break in two and gather themselves up into nothing. We are obliged to assume that the closed curves simply expand into outside space, and that when the circuit is again closed lines come rushing in from outside space—as it were, a series of circumferences, rapidly contracting until they gather into the core. According to this view, these lines must cut the wires as they appear in and disappear from the core. In Fig. 3, let A B represent a section through the axis of a solenoid carrying a current. Lines of force exist, as shown by the dotted lines. Suppose the current to be reduced in strength, there will be less lines through the coil. What becomes of those that disappear? We cannot assume that they are broken in two and pulled out endwise, for, upon the theory, lines of force are never broken. There is no way for a closed curve, such as is represented by the dotted lines, ever to get in or out of the coil, A B, except by cutting the wires that form that coil. There is, therefore, force, cutting in these cases, exactly the same as when the wires of a dynamo armature are swept through the field.

X-RAYS—APPARATUS AND METHODS.[1]—I.

By ELMER G. WILLYOUNG and H. LYMAN SAYEN.

THAT Prof. Röntgen's discovery of the X-ray has initiated many lines of thought promising to greatly extend our knowledge of physical phenomena as well as to revise many of our previously accepted views, is generally admitted. That the practical results accruing to humanity by virtue of the applications of this discovery in surgical and medical practice are of even greater promise and value is equally conceded. The writers have been engaged for a number of months past in developing apparatus and methods for practical work with especial reference to the needs of the physician and surgeon. Your programme committee has thought that some of the results secured might be interesting in view of the fact that very little literature regarding the technique of X-ray work has thus far been published.

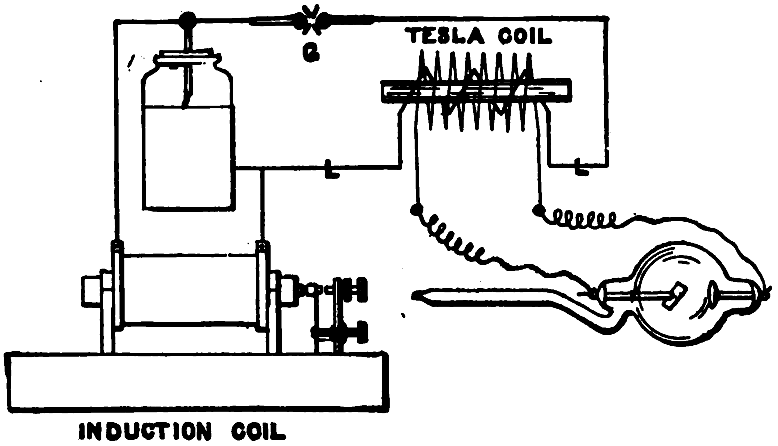


FIG. 1.—TESLA COIL ARRANGEMENT.

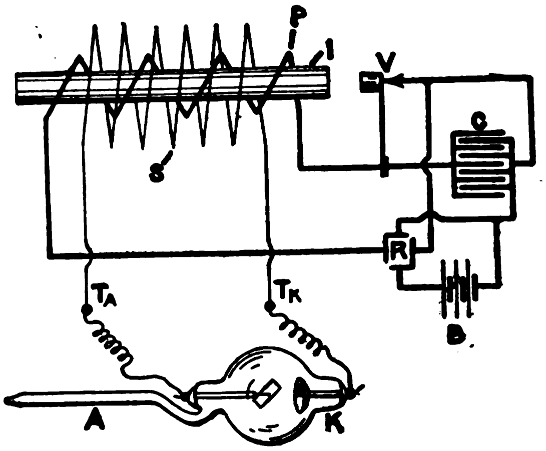

FIG. 2.—ORDINARY INDUCTION COIL ARRANGEMENT.

For conciseness, we divide the matter under discussion into a series of subordinate heads, each of which we shall briefly treat.

Two arrangements of the induction coil are advocated. The one is known as the Tesla or "high frequency" coil, and the other is the direct and old-fashioned use of the simple induction coil in which the high secondary e. m. f. is delivered direct to the terminals of the tube.

The High Frequency Coil.—Fig. 1 shows the diagram of the Tesla combination or "high frequency" coil. It consists, as will be seen, of two induction coils, the induced secondary current of the first being used to charge a Leyden jar. The primary of the second coil is joined, in series with a spark gap, to the two coatings of the Leyden jar. When the Leyden jars are fully charged they discharge across the air gap, this discharge being, by well known laws of electrical circuit flow, an oscillating one of exceedingly high frequency, millions or more oscillations per second. We thus have the primary of the second coil excited by an alternating current of exceedingly great voltage and frequency so that its secondary produces a discharge of still greater e. m. f. and of this same high frequency. So great is this final e. m. f. that it is generally necessary to immerse the entire second coil, primary and all, in a tank of oil, since no solid insulation has yet been found capable of standing these great e. m. f.'s without breakdown.

To excite the Tesla coil, we may use either an interrupted direct current or an ordinary alternating circuit joined directly to the primary of the first coil. But the final result is, in either case, an alternating, high potential, high frequency current. In the tube, therefore, we also have an alternating discharge.

The Induction Coil.—We show, in Fig. 2, the scheme of connections of the simple induction coil. The primary must be excited by an interrupted direct current which may be supplied by primary batteries, storage batteries, or a commercial circuit, as convenience and inclination may elect. The secondary is joined directly to the tube terminals. About the primary is joined a condenser. At break this condenser charges, thus preventing the extra induced current due to the large self induction of the primary, but being short-circuited by the primary at once discharges about the iron core in a direction opposite to the regular "make" current, thus reducing (if correctly proportioned) the magnetic intensity of the iron core to zero. All this takes place so quickly that the practical effect of the action is merely to assist and intensify the dropping off of the core's magnetism; to shove it along, hasten it. Considering the secondary, now, we find that we shall have at "break" an induced discharge of greatly higher e. m. f. than the discharge at "make," owing to the falling off of the core's magnetism at "break" being greatly sharper than its growth at "make." The effect of this is to give secondary discharges in one direction only at all times when the necessary spark gap is not greatly shorter than the maximum spark gap for that particular condition of running the coil, the "make" induced current at such times being of too small e. m. f. to get across the gap at all. This is always the condition when X-ray tubes are used. A further function of the condenser is to suppress burning at the "break" terminals or points of interruption by their taking up of the magnetic discharge of the coil.

In the construction of the induction coil, a number of points may be noted. Our secondaries are wound in sections ⅛ inch thick (according to the plan originally proposed, we believe, by Ritchie). These sections are separated from one another by a large number of discs of paper of a brand especially selected as free from carbon particles and baked at a temperature a little below charring point for some time immediately before use, this to drive out moisture. These sections are then assembled and immediately immersed in a special insulating composition having a very high melting point and some slight viscosity at all temperatures. Paraffine we absolutely prohibit as being too apt to crack and absorb moisture. After cooking for some time in the insulation so as to drive out the last traces of moisture the stack of sections is subjected to a further treatment, by which it is finally cooled. This we consider a point of the highest importance as air present anywhere in the secondary becomes electrified and bombards to and fro, gradually softening the insulation and eventually breaking down the coil. (See Tesla's writings on "High Frequency Phenomena" for confirmation of this point). With this plan of construction we have no static leaks of energy or small direct leaks within the coil itself and deliver the full energy of discharge at the secondary terminals.

We find ourselves able to secure in this way a full inch of spark in all sizes of coils with considerably less than one pound of wire. No. 34 B. & S. We believe that, more than anything else, the large quantites of wire required to produce a given spark length, with many of the coils now in use, is due to the presence of air, and consequent loss of energy by static bombardment, in the secondary. As regards the insulating composition used by us, we may say that we find its power of resistance to spark discharge to be four or five times that of hard rubber. In the arrangement of our secondary we separate it from the primary by a heavy hard rubber tube and, in addition, by a tube of this composition.

---

[1] Abstract of paper read before the Electrical Section of the Franklin Institute, Philadelphia, December 1, 1896.

The Adjustable Condenser.—A coil is working to best advantage when there is a certain definite relation between its primary current, secondary spark distance, and condenser capacity. Speed of break must also be considered. As coils have heretofore been built, however, the condenser value has been fixed once for all and admits of no change, albeit both spark gap and primary current may be so changed. To remedy this, we have devised the form of switch shown in the diagram, Fig. 3, by means of which the condenser capacity may be shifted, at will and instantly, by simply turning the switch. The effect upon the secondary discharge is very marked both volume and musical note of the spark changing with the position of the switch. We find this idea exceedingly convenient in general experimental work with alternating currents, indeed, it being possible with it to alter condenser capacity as quickly and as readily as we may self-induction or resistance. (We have made some experiments in the use of a condenser in parallel with the primary. The volume and vigor of the secondary discharge seems, in many cases, to be greatly increased).

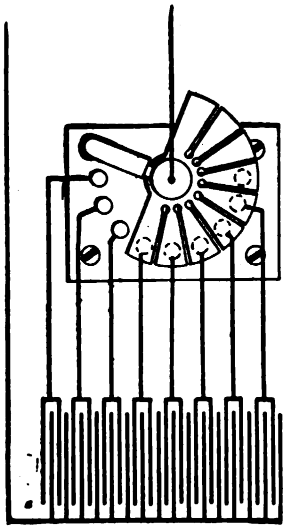

FIG. 3.

In arranging coils to operate from few or many cells of battery it is, of course, merely a matter of winding the primary of coarse or fine wire, the number of ampere turns being kept the same. It is interesting to note, as we have noted experimentally many times, that the larger the primary e. m. f. the smaller must be the condenser capacity employed and vice versa. This is, of course, only to be expected since capacity and self-induction are inverse functions of one another.

Primary Current.—This may be either from primary batteries, storage batteries, or from a commercial direct current circuit. Primary batteries have too high resistance to give sufficient current for coils of much size, say 4 inches and over, unless joined in parallel and then we need a number of such groups to secure the requisite e. m. f. They are a nuisance to attend to, soon run down and are expensive to operate. Storage batteries are exceedingly satisfactory, are comparatively inexpensive to operate, and require practically no attention. Changing them is more or less of a nuisance, however, especially where they must be sent out of the building, as they usually must, besides throwing the entire apparatus out of use while the changing is going on unless one have a reserve set of batteries.

The utilization of a direct commercial circuit, such as the Edison 110 volt, where such is available, is in every way the most convenient and satisfactory. Until Prof. Röntgen's discovery no method of operating large coils upon such a circuit had been developed. Recently, however, several methods have been brought out, notably that of the "air break" with air blast to blow out the spark as used by Dr. Wm. J. Morton, Dr. M. I. Pupin and others. In Fig. 4 we show the form of apparatus devised by us to accomplish this purpose. A Lundell 1-12 horse-power motor is supported upon a base with its shaft vertical. A casting, attached to the motor, supports above the latter a copper can made up of two concentric cylinders joined by a ring below so that the shaft passes up through the inner cylinder and thus avoids the necessity of a stuffing box. From the shaft is hung, well within the can, a heavy brass wheel having stretches of insulating slate let into its periphery. A hard rubber lid fits over the top of the can. Mounted upon this lid are two brushes, one bearing against the wheel periphery and the one against the shaft; suitable springs and screws allow the brush tension to be varied. From the commercial circuit leads are brought to these two brushes the current being first passed through the primary and a rheostat in series.

Before the lid is put in place, the can is filled with distilled water; ordinary hydrant water will answer, although its usual impurity causes the water to soon dirty besides allowing a certain amount of electrolysis during use. With distilled water the break may be run for a number of hours without change of water and very little heating takes place. The real function of the water is not so much to drown the spark as to prevent heating, although it does, of course, also assist in quenching the spark. But a condenser is the real spark extinguisher and this we connect around the break just as we would around an ordinary vibrating break.

The advantages of this break over all forms of vibrating break thus far known and over other forms of rotary break are: (a) Convenience: Mere throwing of a switch being all that is required to start and stop the apparatus. (b) Noiselessness: Only the drowsy hum of the motor being heard. (c) Reliability: No chance of sticking as with vibrating breaks. (d) Variable rate of break: Secured by adjusting rheostat in base of motor. (e) Smooth unvarying fluoroscopic images by reason of the large number of breaks per unit of time.

Two milled heads at top of can permit its lid (carrying brushes) to be withdrawn. A similar head at top of shaft loosens the break wheel and two heads at bottom of can allow it to be lifted away for cleaning and renewal and replenishing of water.

We use three makes and three breaks per revolution and find best results at from 1,200 to 1,400 revolutions per minute equal to 3,600 to 4,800 interruptions. We may secure as many as 2,000 revolutions (6,000 interruptions) per minute by cutting out the motor regulator.

In operation the brush bearing upon break wheel should be positive so as to prevent any electrolysis of the break wheel. We have often broken between fifteen and twenty amperes through this wheel for a considerable length of time without any overheating or overwear of the wheel. Should the wheel wear in time to an undesirable degree it may be removed and turned down. Provision is also made for replacing the brushes when desired.

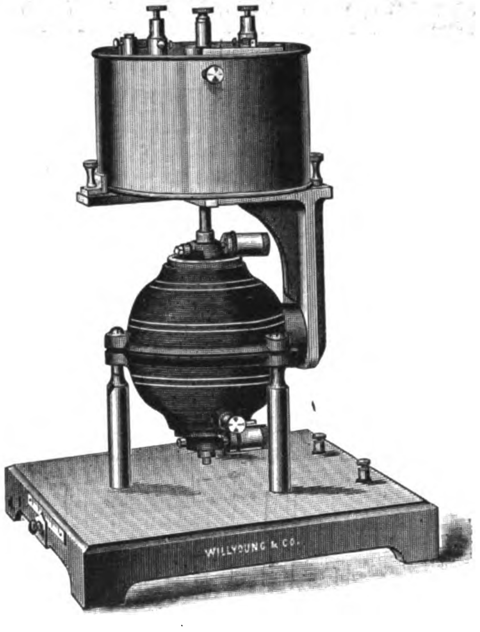

FIG. 4.

General Considerations Regarding Break Frequency.—The question as to whether there is a certain best frequency of break for a given coil or tube or both has puzzled not a few. Very little has been experimentally determined regarding this point. It is certain, however, that, with a given coil or tube, shortness of exposure is not exactly inversely as the number of breaks. Indeed it is often far from being so. Some of the best X-ray pictures that have been taken have been by use of the old "hammer" break of Ritchie and four or five clicks of the break have sufficed. Using the same tube and coil, but a rapidly vibrating or rotary break required forty or fifty breaks to accomplish the same results. It would appear, hence, that the energy of X-ray radiation per break is a function of the number of breaks per unit of time.

We are inclined to believe that this is a matter purely of the "time constant" of the coil. The iron of the core requires a certain time to magnetize and demagnetize. With the breaks few, ample time is given for this process, but when the breaks become rapid this is no longer possible so that the secondary e. m. f. falls. This may easily be verified by observing the maximum spark length of any coil. With single breaks, few and far between, we get much longer spark maximum than if the breaks are frequent. If, however, we increase the primary e. m. f. for the more rapid break we may bring up the secondary spark length to the value given by the single breaks. We should thus be able to shorten the exposure as much as we please by merely increasing the rate of break and the primary e. m. f. at the same time; but here we are limited by the tube which cannot dissipate more than a certain definite amount of energy in a given time and will break down if overdriven. We see, therefore, that whether we use slow breaks or fast breaks, the actual time of exposure remains practically the same, the few breaks requiring to be distributed over the same time as the much larger number of rapid breaks. All this, of course, applies to the photographic plate. For fluoroscopy we require rapid breaks in order to escape the otherwise distressing flickering.

In the above connection particular attention is directed to one point; the rate of break must not be too great. If it is, the iron no longer has time to magnetize and demagnetize. The result is an alternating secondary discharge instead of the direct discharge derived and this means blackening of the tube, rapid fluctuations of the vacuum, and general deterioration of the tube. We doubt whether with any coil of size suitable for X-ray work a rate of break greater than 5,000 per minute should ever be employed.

GROWTH OF POWER TRANSMISSION.

By JOHN McGHIE.

IN the issue of The Electrical Engineer of January 20 an article was published, written to show the extraordinary growth in the use in the United States, of electrical apparatus for power purposes during the past four years. By this is meant electrical machinery used for driving mills, shops, etc., the machinery in mines, and for transmission purposes, over both long and short distances, as distinguished from apparatus used for purely lighting or railway purposes. The figures given were taken from the report of one department of the General Electric Company, the Power and Mining Department, which kindly consented to their publication.

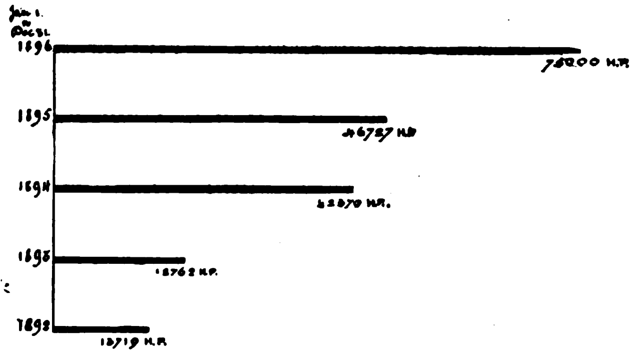

FIG. 1. AMOUNT IN H. P. OF GENERAL ELECTRIC POWER APPARATUS SOLD EXCLUSIVE OF LIGHTING AND RAILWAY APPARATUS.

In order the better to realize the tremendous growth, of which mere perusal of the figures does not convey a fair idea, I have drawn a curve and endeavored to show this growth graphically. Fig. 1 shows the extent of the sale of power apparatus year by year, beginning with the last year of the Harrison administration and continuing through the years '93, 94, 95 and '96.

It will be seen that in spite of the terrible business depression the demand for power apparatus made a bound during 1894, and while not repeating the leap, maintained its position during 1895. The first months of 1896 were months of a gradual restoration of confidence, and if detailed figures were at hand, it could be shown that until the full significance of the presidential nominations came home to the people, the demand for electrical power apparatus increased month by month. It diminished somewhat in the Fall during the preoccupation caused by the electoral campaign, but rose again as soon as the popular will had found expression. The sum total, however, of the year's business reached the very respectable figure, expressed in horse-power, of 75,000. Compared with the business in 1895, and in view of the depression, this showing is extraordinary. From January 1 to July 31, 1895, a period of seven months, the aggregate orders received for power apparatus amounted to 25,737 horse-power. During the same period in 1896, the amount was over 48,000 horsepower.

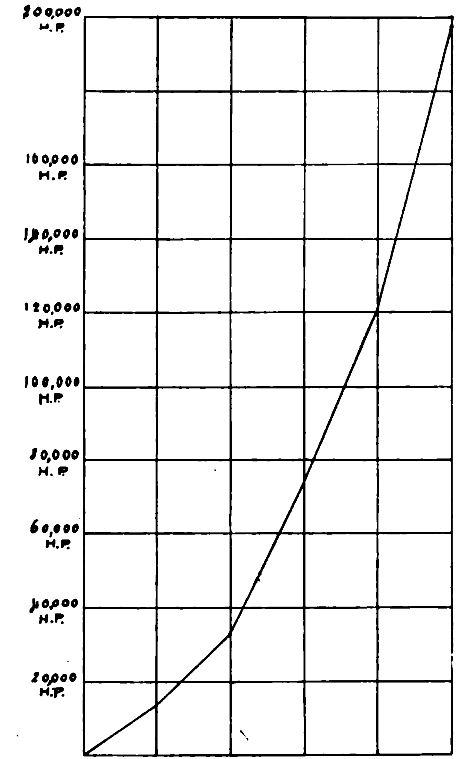

FIG. 2. CURVE SHOWING GENERAL ELECTRIC POWER APPARATUS SOLD FROM 1892 TO 1896.

Fig. 2 shows the total growth of the power business, also expressed in horse-power. It reached with the end of last year 196,587 horse-power. If to this figure were added the aggregate of the power apparatus sold by the many other manufacturing companies in this country, the total would reach so remarkable a figure, as to give good reason for the repeated observation that this country is truly becoming an electrical country.

The power business during 1897 opens well, with the extensive contract for electrical machinery involved in the utilization of the Falls of St. Anthony at Minneapolis, and all signs point to a largely increased use of electricity during the year in mills, mines, factories and for the transmission of power.

NIAGARA POWER FOR THE GRAIN ELEVATORS.

The Electric Grain Elevator Company has been incorporated to conduct a general elevator business for the storage of grain and to buy, sell, and deal in grain in Buffalo. The capital is $350,000, and the directors are Edward W. Eames, Buffalo; Yale Kneeland, Franklin Kneeland, Ormsby M. Mitchell, and Ruleman Muller, New York. The Messrs. Kneeland said last week that they were not ready to talk of the scheme. They will have an elevator with every modern adjunct, and the motive power will come from Niagara Falls.

THE FALLS OF ST. ANTHONY TRANSMISSION.

As already announced in these columns the contract for the electrical utilization of the Falls of St. Anthony at Minneapolis has been awarded to the General Electric Company. It will be remembered that the St. Anthony Water Power Company, and the Pillsbury flour mills and elevator lines were merged into the Pillsbury-Washburn Flour Mills Company, which controlled not only most of the developed water power of the Falls, but also the undeveloped water power below the Falls. A dam to utilize this power was constructed and the total available is calculated at 10,000 h. p.

The water will pass through turbines of Stillwell-Bierce Smith-Vaile manufacture, seven of which, each of 1,000 h. p. capacity, will form the initial hydraulic equipment. The electrical equipment will consist of a plant comprising both direct current railway apparatus for the needs of Minneapolis, and three-phase apparatus for transmission of part of the power to St. Paul, ten miles distant.

The direct current portion consists of two 70 k. w. General Electric multipolar generators, with a speed of 130 revolutions per minute, furnishing current at 600 volts, and two 100 k. w. exciters for the three-phase alternators.

The three-phase generating plant consists of five 700 k. w. alternators, with a frequency of 35 cycles, and an initial voltage of 3,450 volts. This pressure will be raised to 12,000 volts in six step-up transformers of the well known air blast type, and at this voltage the current will go to St. Paul either by overhead or underground wires. This has not yet been settled. At St. Paul the pressure will be reduced in fifteen step-down transformers, when the current will be led into the rotary converters of special type. Of these there will be five. They will resemble in appearance those which the General Electric Company has installed in the power house of the Buffalo Street Railway Company, to take care of the power transmitted from Niagara Falls. They are 8-pole machines, each of 600 k. w. capacity, running at 520 revolutions and turning out direct current at 580 volts. They are designed to operate in parallel with each other, or with the generators now driven by steam in the existing station.

The water power development and the electric plant completed by the Pillsbury-Washburn Company will be operated by the Twin City Rapid Transit Company, a lease having been made between the two companies to that effect. The street railway company will send to St. Paul about 3,000 h. p., leaving 4,000 h. p. to be used at Minneapolis.

When the new power is set to work running the street cars the street railway company will dismantle the Thirty-first street power station, using the room for other purposes. They will continue the main power station at Third avenue north and Second street, and also the power station in St. Paul. These will be kept ready for emergencies, such as a breakdown, a sudden call for extra power and similar occasions. In case there is water enough and conditions are favorable there are still three more units to be installed at the dam.

LITERATURE

ALTERNATING CURRENTS AND ALTERNATING CURRENT MACHINERY. By D. C. and J. P. Jackson. New York, D. Macmillan Company, 1896, 729 pp., 5 x7½. Price, $3.50.

This book forms Vol. II. of the Text Book on Electro-magnetism and the Construction of Dynamos, the first volume of which treated of continuous current machinery. Looking at the volume broadly we must say that the writers have made a most valuable text book on a subject which is not unaccompanied by difficulties. The science of alternating currents, as applied to the construction of dynamo electric machinery can hardly be said to have crystallized into a shape applicable to class room instruction more than a few years ago, and yet in that brief space of time much has been done to bring the science close up to that of the continuous current in exactness.

The authors have constructed the work much on the same basis—and happily so, we may say,—as are the standard text books on other engineering subjects, such as those on the steam engine, hydraulics, etc., and have brought together an enormous amount of matter which has heretofore been scattered in technical periodicals, and elsewhere, and thus entirely unavailable for general instruction purposes.

The authors begin the subject by a discussion of the electric pressure curve and the effect of style of winding on the pressure. This is exemplified by an excellent table, showing the relative dimensions of continuous and alternating current dynamos, including the conductor lengths of the armature wire per pressure generated. The authors point out that with a fixed size of armature and depth of winding it is apparent that an alternating current armature will carry only about one-half as much wire as is carried by a similar continuous current machine. Hence in order to gain an equal output from the machines it is necessary to increase either the size of the alternator armature or its speed. The latter expedient has largely been used in the past, though we are rapidly coming to direct connected alternators of large size. This is followed by a chapter on the various types of armature windings for alternators, illustrated by numerous diagrams, which, however, are intended to illustrate principles, rather than to give a series of working diagrams. We here also find a discussion of induction alternators, and their construction; insulation, and the method of building up armature coils, etc.

In a work of this nature, treating of a subject involving induction phenomena at every turn, naturally much space would be occupied in the discussion of these effects, and we therefore find much attention given to the treatment of self-induction and its counterpart capacity. In this part of the work the authors define briefly the terms discussed, and treat successively of the laws underlying inductive pressure; the units of self-inductance accompanied by various examples of inductances, together with the effect of the angle of lag, of capacity and similar effects; the methods of measuring self-induction of alternating current power, etc., are also discussed. This is followed by a chapter devoted to graphical, analytical methods of solving problems in alternating-current circuits.

These chapters lead naturally to others relating more to practical construction, and include the magnetic circuit of alternators, in which the losses are defined, and in which we find rules for the determination of the number of armature conductors, the self-inductance of the armature; the field windings, etc.; characteristics, regulations, and efficiencies of alternators. Methods of testing in the laboratory, as well as shop tests, round out this part of the subject in a very practical way.

The transformer next claims our attention, and their treatment in general follows closely that adopted in the preceding part of the work, special reference being had, of course, to the nature of the principles and actions underlying the transformer. Polyphase conducting systems and the measurement of power in polyphase circuits form the subject of a brief but very practical chapter, in which special reference is made to methods actually employed in practice. Under the head of alternating current motors, we find a very extended discussion of the various principles involves in this class of apparatus, and there is no part of the subject which seems to have been neglected, though, of course, in a work of this kind little more than a general outline can be given of the topics treated. A chapter on polyphase transformers closes the work, which has a number of short appendices on electrical resonance, oscillatory discharges, etc.

We believe this is the only text book on the subject worthy of the name, and it is, in our opinion, a matter of congratulation that the student has at last at his hand something adapted to his needs. Of course no work can be expected to give the student a complete knowledge of all that has been done in the department to which it is devoted. The authors have designedly, and we think with great advantage, omitted all descriptions of machines and apparatus, except where such descriptions were absolutely necessary for a clear understanding of the text, but they have very wisely assisted the student in these studies by numerous references to original articles in periodicals, and other works, which treat specifically of the topics to which they refer.

Where there is so much of merit it would indeed be ungracious to offer criticism on minor points, and we can only repeat our expressions of satisfaction at the appearance of so meritorious and timely a work.

FROM A WESTERN COMPANY.

"It is with pleasure that I ask you to send us the bill for the subscription to your paper for 1897, and by so doing testify to our appreciation of it as a newsy, up-to-date journal. For the past four or five years we have taken nearly all the American electrical publications, but since your connection with The Electrical Engineer, it has stood at the head of the list."

VOL. XXIII. NEW YORK, JANUARY 27, 1897. No. 456.

BREAKBACK BURDENS.

IN addressing its constituents, our new and excellent contemporary "City Government," which has been doing good work towards the creation and adoption of better methods for managing municipal affairs, remarks very sententiously: "You must be a wise man to be a city official." This is neat and true, but it generally escapes acceptance, and, in the current passion for making the municipality do everything, appears to be entirely forgotten. Whoever turns over the valuable pages of "City Government," filled with data of all kinds, realizes at once how wide the scope of municipal affairs has become; but the paper itself clinches the matter in a cogent appeal for support in which, by the way of illustration, it enumerates some twenty distinct and separate matters which any modern mayor or alderman is expected by his constituents to know all about. This list is by no means exhaustive, for we could easily double it ourselves; but it includes such trifles as electric and gas lighting, trolley travel, police, franchises in general, parks, paving, garbage, sewers, libraries, education, water supply, systems of taxation, saloons, the social evil, fire, handling public securities, building up a city, and a few other like trifles of no consideration.

But, seriously, is not such a list in itself one of the explanations why city government so often breaks down, and why it is unwise to increase the burdens—or the temptations—of those who are entrusted with the management of the city's affairs? Strive to master these subjects as they may, and even with the aid of such admirable guides and mentors as the paper we have named, the mayors and other elective officers can but often break down or fall short in their efforts to keep up with the mass of miscellaneous duty heaped upon them. These duties require expert skill or knowledge, not only in those who carry on the departments, but at least to some extent in those who are the legislative body; and if the masters are ignorant, the servants are not likely to remain either expert or honest in the long run. Whether the city be regarded as a small state or as a business corporation of the citizens, this increase in number and variety of functions is a startling menace to good administration of affairs in general.

Analogies from old times are not necessarily safe and sound, but it does seem to us that, as in old Rome, the dangers of coming social disintegration increased about in proportion to the degree in which the government absorbed all the functions involved in preserving, punishing or pleasing the citizens, so in our modern tendencies toward centralizing all kinds of heterogeneous management and ownership in the city, we are running risks that are perilous for future social welfare. The assumption that everything goes well and cheaply the moment a public functionary assumes it, or is paid for doing it, is based on a blind disregard of all the teaching of history and all the observation of current events. The more a state or city engages to take care of its citizens the more helpless those citizens tend to become; the latest proof of which is seen in the fact that the new laws of Austria and Germany compelling universal insurance have been followed by an alarming increase in the number of accidents. And so it goes. One man wants a state church, another advocates a national theatre, a third favors public prizes for horse races, a fifth wants a city printing office, the next fights to set up a city bakery, and every one has designs, good and bad, on the purse that can only be filled out of the ever growing burden of heavy taxation. People have literally been going crazy in their zeal for taxing other persons in support of their hobbies and whims, and we need not have very strong prejudices in favor of leaving a few things to individuals or corporations—such as lighting and street railways—if we should venture to express a hearty sympathy with the movement just started in far New Zealand for personal liberty and against having the state or city government choke every impulse for freedom and initiative out of its people. If the Liberty League fails, and the majority insists on being governed by its minority in uniforms, we hope to be able to move on to Mars.

INCANDESCENT LAMP AND CENTRAL STATION.

THE central station operator is inclined to look upon the supply man as a necessary evil, whose sole desire it is to sell him something, the exact value of which he can not determine until it is too late to claim a rebate. There has been some justification in the past for the existence of this sentiment, but there ought not to be any room for it at the present time, or in the future, since every central station ought to be equipped with the means of testing the supplies purchased by it. Yet, on the other hand, it cannot be denied that manufacturers have constantly given their customers good advice and points worth noting. Of the latter order are some of the hints contained in the admirable paper read by Mr. F. S. Terry before the Northwestern Electrical Association. It cannot be too often repeated that one of the essential factors in the life of incandescent lamps is uniformity of pressure; and yet how many central stations are there, particularly among those of the alternating type; which have the means of knowing the pressure at all points of their distribution system; or, having the means, maintain the pressures constant? With this condition of affairs, of what avail are the guarantees of lamp manufacturers as to the life of incandescent lamps? This brings us to the question of the much-talked-of 2½ watt lamp. As Mr. Terry correctly points out, such a lamp would require even closer regulation that the present 3.1 watt lamp in order to give at all satisfactory results as to life, and hence even if such a lamp were commercially available it would, under existing conditions of central station operation, prove impracticable. This whole question of life and efficiency of lamps must sooner or later receive the attention it merits; indeed, we know of scarcely any other industry where goods are bought and sold on so little knowledge of their intrinsic value. As recently pointed out in these columns, a step in the right direction has been made in Germany, where manufacturers and central station operators have combined to draw up a set of specifications to which lamps must conform, and in which an adequate number of lamps from each package are subjected to a regular test, upon which the purchase or rejection of the lot depends. We see no good reason why a similar agreement should not be arrived at in our own country, and the German arrangement even improved upon. Thus a stipulation might be agreed to by which lamps not coming up to the full standard, but not bad enough to reject entirely, would entitle the purchaser to a rebate; while, on the other hand, lamps exceeding the standard performance would entitle the manufacturer to a bonus. Such an arrangement would be equitable to both sides, and no manufacturer having faith in his products would, we think, object to it. Of course, an agreement of this nature would require the equipment at central stations—where such equipment did not already exist—of a photometric room and standard measuring instruments, for without such, no comparative tests of any kind would be impossible. This feature of the case does not present the difficulties that it would have done ten years ago, since to-day direct reading electrical measuring instruments can be obtained whose indications can be relied upon to within a fraction of 1 per cent., and which can be readily calibrated. The only weak spot would still be the photometric tests where the standard of light as well as the personal equation might be disturbing factors; not sufficiently great, however, to render the object aimed at nugatory. We throw out these hints in the hope that they may be discussed and their practicability or non-practicability determined.

THE NORTHWESTERN MEETING.

THERE was some pretty plain talking at the convention of Northwestern Electrical Association, and on no subject was there a freer exchange of opinion than on that of municipal ownership of electric lighting plants. That many of the members are sorely troubled about the situation of affairs is evident, but the remedies suggested to counteract the evil were not many. Among them we note the suggestion that central stations should institute what amounts practically to a boycott of those manufacturers of electrical and steam apparatus who equip municipal plants. We do not believe in boycotts under any circumstances, and in the present case fail to see what particular object would be gained by such a course. If persisted in it would surely turn the boycotted companies into pronounced enemies of the private lighting companies, where now they at least profess to deprecate the establishment of municipal plants. As to the origin of the municipal plant agitation, it was truthfully pointed out that much of it is due to the over-bonding and capitalizing of many of the early plants. Still there is something to say on the other side of this question, having in view the uncertainty and risk involved in the establishment of a new industry, which required a strong incentive to enlist capital. To our mind, the only proper and feasible way to counteract the present tendency is to inaugurate a campaign of education, to take up each case individually and, by the dissemination of authentic information as to the actual cost of operating central stations to municipalities, place every voter in a position to form his own judgment in the matter. There are enough precedents of failures of municipal plants already available to back up the anti-municipal arguments, and we have sufficient faith in the fairness and judgment of the American voter to let him decide the question for himself. We are convinced that many of the municipal stations erected in the past were the result of misinformation as to the true conditions involved, and that if the question were to be submitted at the present time to the same voters a tidal wave of opinion in the other direction would probably be noted. We do not ignore the fact that individual municipal plants have shown good results, but it can be readily shown that such instances are due to special circumstances and conditions which cannot be depended on to obtain in even a small fraction of the cases which have arisen in the past or may arise in the future; and even in the cases referred to there is no telling when the conditions, now so favorable, may turn the other way.

"ONE SIDED REPORTS."

UNDER the above caption our esteemed contemporary, the American Machinist, dilates to the extent of two columns on the large predominance of the human element in technical reports, which calls for the assignment of a high value to the personal equation of the writers of such reports. Our contemporary is moved to make these remarks by the appearance in our columns of the record of a test of an electric mine pumping plant as compared with a compressed air plant, which Mr. Lewis Searing, a mechanical engineer, contributed to our columns recently. It would seem that our compressed air friends do not like the prospect, and Mr. Searing has also been criticised abroad for alleged errors of commission as well as omission. The answer to an English critic which Mr. Searing makes in another column, shows that he stands on safe ground and is well able to take care of himself. We must confess to some amusement at the bland statement of the American Machinist that it has no interest in the one greater than the other, that is, electricity and compressed air, and that it will gladly do what it can to secure adequate representation for each. This is very kind of our contemporary, but we note on the very editorial page which criticises Mr. Searing's tests an editorial note on compressed air cars in New York, which could hardly be called unfavorable to compressed air—indeed, which some critics might term distinctly encouraging to the promoters of those enterprises. On the other hand, we think we have discerned a marked tendency on the part of our contemporary in the past to show up electricity in as little favorable a light as could be done consistent with established facts. Perhaps this may have been an illusion, but no one who glances through the pages of our valued contemporary's last two issues would consider it inimical to compressed air.

TELEPHONE VS. STREET RAILROAD.

WE note that the old fight between telephone exchange and street railroad has cropped up again at Canton, O., where the Central Union Telephone Company wants an injunction against the Canton Light, Heat & Power Company because the latter has recently so handled its generating plant as to cause a fearful inductive buzzing in the adjacent telephone lines. The trouble is sufficient to make several subscribers order out their instruments. Such a situation should be easily remediable, and we hope it will be. In the meantime it is interesting to note how steadily Cincinnati has remained a double trolley wire city, and a recent number of the local paper "Chic" quotes a number of very pretty things said about the roads and their service by distinguished citizens. This satisfactory state of affairs we can perhaps trace to the influential presence of telephonic interests in the street railway management, in the person of Capt. G. N. Stone, so worthily associated with Mr. John Kilgour. We note that Capt. Stone in some recent remarks gave the railroad company credit for no less than 200 miles of single track, with 7 electric power houses, 3 cable houses, 23 car barns, and 1,183 cars. These are striking and splendid figures, but as indicated above, the things that strike us most are the successful use and increase of the double overhead trolley wire and the harmony between telephone exchange and street railway. Long may the state of peace continue! But as to the double trolley it is funny that nobody else seems able to make it go or wants it. The passenger in Cincinnati rides 14 miles for 5 cents.

DIRECT DRIVEN UNITS.

THIS is certainly the day of big units in power house practice, but a tendency exists perhaps to exaggerate the extent of such work. A well known mechanical engineer remarked to us recently that he doubted whether in electrical work there were to-day in this country a full hundred direct driven generating units of 1,000 h. p. each, and that he was confident a large proportion of them ran nearer 600 h. p. half the time. He thought there was plenty of work to be done in the field up to 500 h. p., and that for a long time to come the bulk of work and improvement would lie there. It must be confessed that these remarks betray a shrewd observation of the actual conditions. Another engineer in the steam industry informed us of his belief that the direct driven unit, no matter what size, was a delusion as to economy, and that he could beat it, especially with a rope-driven combination of engine and dynamo each of the greatest possible economy and efficiency for the specific employment. All of which is very interesting—if true.

IT is generally the little thing that helps bring home a great fact to every body, and so within the last few days the swallowing of a pin badge by tiny Tommy Madden, its skillful location in his throat by Dr. W. J. Morton with the X-ray, and its successful removal by surgery, have interested and excited all New York. Such a thing has done more than anything else to show that the knife and lancet can now be safely guided, and that the means of rescue from internal dangers have been vastly augmented. We do not wonder at the enthusiasm shown in the clinic by the surgeons and students. Dr. Morton's success and accuracy of location with so large and clear an X-ray plate serves to mark and emphasize the new departure, and in this respect again he proves himself a worthy son of his great father. The X-ray hasn't done much outside of surgery, but there it is already known to be an inestimable boon to mankind in its practical applications.

THE success of the Niagara power enterprise on the American side of the dividing waters, has naturally provoked some jealously on the Canadian side, and we regret to see a clamor raised in several Dominion newspapers for a non-extension of the privileges granted on their side to the Canadian Power Company, which consists virtually of the same men as the American company. What good will a forfeiture do Canada? The Dominion is to-day getting $25,000 a year for absolutely nothing, and if the franchise terminates, that stops too. Absolutely no one will be benefited by lapse. On the other hand, to maintain the present status will in time bring power on their side. This big work takes time and money, and meanwhile, for our own information, we would like to inquire how many Canadians are ready to go to Niagara, as Americans have been, to use the power that can be generated? We venture to express a modest conviction that the men interested would need very little such inducement from would-be users of their power anywhere within reasonable reach.

ELECTRIC LIGHTING

THE ENCLOSED ARC LIGHT.[1]—I.

By L. B. MARKS, M. M. E.

THE unprecedented industrial utilization of the enclosed arc light in America during the past two years has aroused the attention not only of American electricians and engineers, but of scientists the world over. Although some of the earlier inventors in this field achieved a modicum of temporary success, every attempt to introduce the enclosed arc lamp commercially eventually met with decided failure.

Before going into the details of the subject or presenting a sketch of the earlier history of the art of enclosed arc lighting, it may not be amiss to point out the characteristic distinction between the ordinary arc and the enclosed arc. The ordinary arc, commonly known as the open arc, is generally enclosed in a globe more or less tight at the top and bottom. This is also the case with the enclosed arc. In the former, however, the arc depends for its efficient operation upon an excess of air or oxygen-bearing gas, while in the latter, provision is made for the partial or total exclusion of the atmosphere. With this preface I shall now revert for a few moments to the earlier forms of enclosed arc lamps.

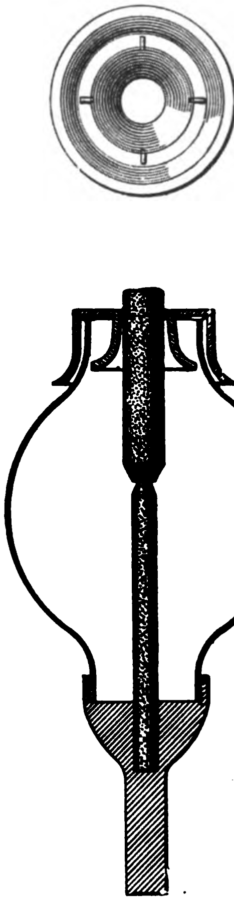

FIG. 1.—VENTILATED ENCLOSED ARC.

HISTORICAL SKETCH.—The history of the art may be said to date back to about 1846, when Wm. E. Staite first produced an enclosed lamp in which one carbon was supported on a rod passing through an air-tight bushing into a globe, and the other carbon mounted in a tube projecting through the base of the globe, and fed by a rack operated by clock-work. In this lamp the arc was struck by pushing the carbons apart by hand. At that early date Staite pointed out that "the more rarefied or de-oxygenated the air around the point of ignition is, the more continuous and brilliant the light, hence may be deduced the propriety of enclosing the electrodes in a vessel of small dimensions hermetically sealed from the external atmosphere, but with a valve in it for the escape of the included air when the expansion begins to exceed those limits which experience may show to be compatible with the safety of the apparatus."

About a year later Staite improved this lamp in various details. Instead of springing the arc by hand, it was done automatically by an electro-magnet. The arc was enclosed in an air-tight globe and the regulation effected by electro-mechanical means.

After Staite's experiments there followed a period of inactivity in this line, and it was not until the '70's that the work was again zealously taken up. In 1878, F. H. Varley brought out a lamp containing an air-tight chamber in which carbon powder was allowed to fall from one electrode to another as from an hour glass, the carbon being heated to incandescence in transit. The mechanism of the lamp was so arranged that the carbon, after falling through the arc space and becoming incandescent, was again returned by suitable carriers to go through the same operation. In 1879 George G. André devised an electric lamp in which the carbons were enclosed air-tight in a large globe, no provision having been made for egress or ingress of gases. The oxygen of air in the globe gradually combined with the volatilized carbon, when the lamp was in operation, until finally the electrodes burned in an atmosphere consisting largely of carbon gas.

About this time there was considerable activity in the production of enclosed arcs of a different type, viz., the semi-incandescent arcs. In this form, the carbons or other electrodes as the case may be, are in imperfect contact, the point of juncture being heated to a state of incandescence when the current is passed. Such was the lamp of Brougham in which the carbons were enclosed in a receptacle from which the atmosphere was excluded; no arc was sprung in this lamp, the light emanating from the incandescent points. Following closely on this, in the year 1880, André and Easton produced a lamp similar to the older type already described, but differing from the latter in that the movable carbon was maintained in contact with the negative in a closed chamber, and was fed upward as the carbons burned away, the feed being effected by a weight released by a magnet acting on a friction disc. The same type of lamp is also described by Hedges, who substituted a metal disc for the metal carbon, the positive carbon feeding and continuously bearing against this metal disc and heating the joint to incandescence.

The well known lamp of Werdermann, which was brought out in 1882, is another type of the typical incandescent arc. In Werdermann's lamp the carbons were enclosed in an air-tight globe. A thin carbon pencil was propelled against a large negative electrode by a spring; the pencil passed through a block of magnesium or other refractory substance and a considerable length of the electrode between the block and the contact was rendered incandescent. After the lamp was started the oxygen contained in the globe quickly combined with the carbon, the residual gases thus consisting of nitrogen and carbonic oxides. Among other lamps of the same type, in which no true arc was sprung, were the earlier forms of Jansen in 1875 and Scott in 1878, and subsequently those of Rapieff, Nordenfeldt, Pilloux and Quesnot.

The record of development between 1880 and 1884 shows that a number of lamps of the enclosed type in which a true arc was sprung were produced. The principal ones were that of Varley, in which the arc was enclosed in a glass globe or shade filled with carbonic anhydride, or hydrogen, or dried nitrogen; those of Wallace, Brewer and Menges; that of Beardslee, in which the arc was enclosed in a small globe, air-tight at the bottom and having a contracted neck at the top through which the movable carbon passed; that of Baxter, in which the entire lamp mechanism was enclosed air-tight, provision for the egress of heated gases under pressure being made by suitable valves connecting the enclosure with the outer air; and that of Short, similar to the last. Besides these there were several others, differing from those cited only in detail.

The Enclosed Arc in America.—In America the first attempts to utilize the enclosed arc in commerce date back to the early eighties, when Beardslee produced an enclosed arc and Wm. Baxter experimented with long-hour enclosed lamps. Baxter's experiments and tests covered a period of years but resulted in failure. From time to time other inventors took up the subject, but as the ground covered by them differs very little from that of earlier efforts, it will not be necessary to dilate here upon the various schemes attempted since the original presentation of the Beardslee and Baxter lamps, respectively. This brings us to the time when Howard took up this line of work in conjunction with me about five years ago.

Most of you are familiar with the tests reported by me in a paper read at the International Electrical Congress at Chicago in August, 1893. That paper was hastily prepared to present a subject which, in the opinion of those who had witnessed the trials, was deemed worthy of the fullest description possible at the time. The arrangement of parts disclosed in the lamp referred to in the paper at Chicago was rather unique in some details, but in principle did not differ essentially from earlier forms.

---

[1] Read before the Société Internationale des Electriciens, Paris, France, Jan. 20, 1897.

It was thought at that time that the enclosed arc would have a large field on constant current circuits and an attempt was made to equip existing lamps with the enclosing device. This device, which was very crude, consisted of a cylindrical glass receptacle clamped by discs which pressed tightly against its upper and lower edges respectively, the lower end being closed air-tight and the upper end provided with an opening through which the positive carbon passed. In this equipment the negative electrode was made of metal. I shall have occasion to allude to this metal negative later on; also to point out the prime cause of failure in this, as well as in many of the other forms of enclosed arc herein referred to. Subsequently another device was used which consisted simply of a small bulb fitted practically air-tight at the bottom and closed on top by a valved cap through which the upper carbon fed. This appurtenance could be attached to any arc lamp. The negative electrode was in this case made of carbon. A circuit of lamps of this type was tested in the winter of 1893 and early part of 1894 at Buffalo, N. Y. The report and discussion of the tests were published in the electrical journals of the time, also in the Transactions of the National Electric Light Association, Washington, D. C., Convention, 1894.

We come now to the ventilated enclosed arc which was devised by me a few years ago and described in some of your technical journals. You will note in Fig. 1 that the enclosure is provided with means for directing the path of the ingress of air and the egress of gas. You observe that the bulb is pressed tightly against a practically air-tight bottom and is closed at the upper end by bell-shaped cap or plug wherein resides the novelty of the equipment. This plug is made of metal and is shaped so that the rim is brought closely adjacent to the exterior wall of the envelope, thus providing a narrow annular passage for the outside air into the envelope by reason of which the entering air is highly heated in transit before reaching the interior of the bulb. You will also see that the tubular opening through which the upper carbon feeds is conical in shape, the opening at the top being only a little greater than the diameter of the electrode so as to permit a free feed of the latter and afford an obstructed egress for the gases from the envelope. As the closure touches the glass only at four points, shown in the engraving, the tendency of this arrangement is for all egress to take place by way of the central tubular opening and of ingress by way of the bell-shaped chamber. In other words, the convection currents naturally formed by the heat of the arc are taken advantage of to secure a steady and uniform circulation of oxygen-bearing gas in the enclosure. By the use of this equipment the life of the electrodes was prolonged three or four times, the lamps being operated on a constant current circuit under practically the same conditions as to current and voltage, as the open arcs. In practice it was found that the ventilated enclosed arc had many shortcomings and could rarely be operated under favorable conditions on commercial circuits.

INCANDESCENT LAMP IMPROVEMENT.

BY JAMES CLEGG.

THE possibilities of improvement of the incandescent electric lamp can only be in the emissivity of the filament and in the maintenance of a high vacuum in order to prolong its life. Metallic oxides, such as the rare earths, as used in the Welsbach lamp, cannot be employed by themselves alone, because they are not electrically conductive and they cannot be intermixed with, or used as a covering for, carbon, because their expansion by heat differs so greatly from that of carbon. If carbon and metallic oxides are mixed together they swell and crack when heated. If the oxides are made to coat the carbon, neither will they hold together when heated. The Welsbach mantle consists only of metallic oxides.

It has been universally accepted by lamp authorities that only a filament of carbon, and the more graphitic the better, will work efficiently in an incandescent electric lamp, and referring to Mr. Howell's letter in The Electrical Engineer of January 13, I have found that the more homogeneous and solid, and more even and uniform is the surface, the greater the efficiency and length of life at a given candle-power. Tests which I have made have proved again and again that a filament with a smooth surface of a light color of the least porous graphite will emit 16 candles of light at a lower temperature, and consequently with a higher efficiency and longer life, than a filament of a dark shade and a rough surface. This is a simple law of light emissivity of all bodies. A white body with a smooth surface is the most emissive of light.

The best incandescent lamps have the greatest homogeneity of structure and evenness of surface with a coating of the least porous graphite deposited on them at the highest temperature, and these results will be obvious to all incandescent lamp makers if they will examine the product under the microscope, and then compare the emissivity and life with that of other different filaments.

INCANDESCENT LAMPS.[1]

BY FRANKLIN S. TERRY.

THE subject of the incandescent lamp has been so many times and so ably treated from a scientific standpoint that I could add little that would be new and I will, therefore, confine my attention principally to those points which will be of practical interest to the central station.

The making of an incandescent lamp requires more than thirty distinct processes, most of which affect its quality rather than its appearance. The character of the filament, the way it is flashed and the exhaustion may generally be said to have most to do in determining the quality, but the defect in a lamp may be traced to a defect in either the filament, the glass, the platinum, even the base, or due to poor workmanship in any one of the several processes in putting them together.

As light is the only useful product, the incandescent lamp may be said to have a real efficiency of from 3 to 5 per cent., the rest being wasted in heat. An incandescent lamp may be operated at such a low voltage as to give heat but no light. The filament that will stand the greatest degree of heat without vaporizing, other things being equal, is the best.

It is customary to state as the efficiency of an incandescent lamp the watts of energy required to produce one candle of light. By increasing the voltage we increase the light more than in proportion to the increase in the energy consumed and the lamp is then said to be more efficient. For example, a lamp giving 16 candle-power of light at 100 volts pressure and consuming 56 watts of energy we would call a 3½ watt lamp. If we should increase the voltage to 110, the candle power would be increased to 28, the energy consumed to 70, the watts per candle would then be 2½ and we would call it a 2½ watt lamp. There is no difference in the lamp itself between what is termed a 2½ watt lamp and what is termed a 3½ watt lamp.

As lamps are operated at a higher efficiency, their defects become more apparent. If one is satisfied to operate a lamp at an efficiency of 6 or 7 watts per candle (and such lamps are made and sold), what is in reality a very bad lamp may give a customer good satisfaction.

The life of an incandescent lamp will be shorter as it is operated at a higher efficiency, or in other words at a higher voltage. For example, if at 3½ watts a lamp would have a life of 2,400 hours, at 3 watts it would perhaps have a life of 1,000 hours and at 2½ watts a life of 350 hours. It is not correct to take the life of an incandescent lamp as the measure of its quality. The practice of asking for guarantees of life has been nearly discontinued. The absurdity of such a guarantee is apparent when we consider that the conditions governing the life are under the control of the one operating the dynamo, and further, the life of a lamp is a factor of small relative importance in determining any economy in incandescent lighting. Every manufacturer can make long life lamps and those that are inferior in quality will usually be found to have a long life.

The decline in candle power is due to an increase in the resistance of the filament; consequently it then requires a higher voltage to produce the same amount of light as at first. Every incandescent lamp will decline in candle power after a certain number of hours burning. If operated at a higher voltage or efficiency the decline will be more rapid. The difference between different makes of lamps as to the rate of decline is due principally to the filament used and the exhaustion, and when operated at the same efficiency this rate of decline is the correct measure of their relative quality.

Sometimes central stations raise the voltage that they may give customers a better light or in order to burn out the old lamps. This is bad practice as it will result either in burning out new lamps or reducing the candle power until they will no longer give a serviceable light. Lamps should be "smashed," as it is now usually termed, when they have ceased to give a satisfactory light and should be replaced by new lamps of full candle power.

---

[1] Abstract of a paper read before the Northwestern Electrical Association, January 20, 1897.

If a lamp bulb has become black, it is almost a sure indication that the lamp has been subjected to a higher voltage than was intended, or has been burning a good many hours. Blackened lamps should not be complained of as defective.

Probably there has not been an article written on the operation of incandescent lamps without calling attention to the importance of maintaining a uniform voltage and still this is not fully appreciated in many central stations. The trouble is sometimes due to incorrect station voltmeters, sometimes to large pressure loss on the lines; and on alternating circuits may be due to poor regulation of transformers. A fluctuating voltage must always result in an unsatisfactory lighting service. If it would be an advantage to the central station to have a higher efficiency lamp, the first step to take in that direction is better regulation, which will result in the lamps being of higher efficiency when operated at the normal voltage.

In a paper read at your last year's meeting, Mr. Buckley recommended the use of 2½ watt lamps, "and 2 watt lamps if you can obtain them." You all have 2 watt or 2½ watt lamps in your stations now. Just increase the voltage at which they are burned until the energy consumed divided by the candle power of light gives you 2½ and you have a 2½ watt lamp. If you are using the best lamp you will have the best 2½ watt lamp that can be made. Mr. Buckley gave some figures showing the saving made by using 2½ watt lamps. The figures given exaggerated the saving as no allowance was made for the more rapid decline in candle power of the 2½ watt lamps which in practice will soon lose from 40 to 50 per cent. of their candle power. The customer that wants a light of 16 candle power will not be satisfied with one that gives but 8 or 10 candle power, even if it may cost less to operate.

The 2½ watt lamp would not do at all on most central station circuits, as they are now operated. When overrun in voltage they would be immediately burned out or the candle power would afterwards be so low as to make the light unserviceable. A high voltage will injure so-called high efficiency lamps more than those of lower efficiency. With better regulation you can use higher efficiency lamps and it is profitable to operate lamps at as high efficiency as will give satisfaction to your customers. Probably a 3½ watt lamp will give the best satisfaction in most moderate sized stations as at present operated.

One difficulty in furnishing lamps to central stations is the lack of knowledge of how the station is operated. Often the voltage is higher or lower than is stated, due perhaps to an incorrect voltmeter and lamps made for the voltage as ordered would not be satisfactory. Again the voltage may be irregular and a lower efficiency lamp would be more suitable. If all central stations were operated the same it would be much easier to furnish a lamp that would always give satisfaction. This will perhaps explain how it is that a certain make of lamp is considered the best at one station and the worst at another.

Lamps can be obtained of from 4 candle power to 500 candle power. In this country the 16 candle power lamp is the standard and is the lamp mostly used in both stores and residences. In some of the foreign countries the 8 candle power lamp is the standard. In store lighting a bright light is wanted and I predict that in the near future the standard for that service will be higher than at present, perhaps 20 candle power. In residence lighting the demand is for a certain number of separate lights and that the monthly bills shall not exceed a certain amount. There are many places in residences where the smaller candle power lamps, consuming less energy, will give as good satisfaction as the 16 candle power. In decorative lighting and in sign work a small candle power lamp, even as low as 4 candle power, will give quite as good an effect as the 16 candle power, and with about one-third the cost for energy.

As the purpose of the business of central station electric lighting is to make a profit and pay dividends to the stockholders, every intended economy must be judged by its effect on the profits or dividends.

Sometime ago I obtained from a number of electric lighting central stations statistics showing the capital invested and the results of their operation, and from an average of these I have made up some figures that I believe fairly represent the results that will be obtained in the average station.

We will take for our example a station having an investment of $100,000. I found the average gross receipts of the stations above referred to was 26½ per cent., of the investment, or this station should have a gross income of $26,500.

The average price charged customers for energy was 15 cents for 1,000 watt hours, which would be equivalent to ¾ cent. per lamp hour for a 50 watt lamp. The electrical energy that this station would supply to customers in a year would, therefore, be 175,666 k. w. hours. Operating expenses, including general expenses, taxes and ordinary repairs for the year, $14,700, or about 8⅓ cents per k. w. hour.

If the business is profitable the earnings should be sufficient not only to pay dividends, but in addition provide for a reserve or sinking fund in order to return to the stockholders their original investment at the end of the natural life of the business and the smallest amount that should be laid aside for this purpose is 5 per cent. of the capital annually, or for this station the sum of $5,000, or about 3 cents per k. w. hour for the energy delivered to customers. This would leave a sufficient amount to pay dividends at the rate of about 6½ per cent., which certainly is not too large, considering the character of the investment.

Now let us see what part of the cost of operating expenses is the item of lamp renewals. A 50 watt, 16 candle power lamp we will assume will have a life of 600 hours, or the total consumption of energy of this lamp during its life will be 30,000 watt hours. If the cost of the lamp is 18 cents each, this will be equivalent to 6-10 cent per 1,000 watt hours, or 7 2-10 per cent. (about 1-14) of the operating expenses, or including the reserve fund, which is a legitimate item of the cost of operating, the cost of lamp renewals will be 5 per cent. (or about 1-10) of the total cost of energy. What effect would one cent difference in the cost of each lamp have on the dividend rate?

Taking the total energy generated for the station referred to above, 176,666 k. w. hours, and dividing by 30 k. w. hours, the energy consumed by each lamp during its life, we find that this station would annually consume 5,888 lamps.

A difference in price of one cent per lamp would, therefore, amount in a year to $58.88, or 1-17 of 1 per cent. of the investment, or it would take seventeen years for one cent added to the price of lamps to equal 1 per cent. of the capital stock.

Now let us turn to the question of quality. Are all incandescent lamps practically the same? Considering for a moment the lamp to be a device for generating heat, we would certainly expect to find that two different makes would differ from each other at least 1 per cent., or if one lamp transformed 95 per cent. of its energy into heat, we might reasonably expect another would transform 96 per cent. into heat. These would not then differ from each other very much in their general conditions, but one would transform 5 per cent. of its energy into light and the other 4 per cent., or in the amount of light produced for the same consumption of energy they would differ from each other 20 per cent. I have stated it this way to show that such a difference cannot be considered absurd.

What is the value of this difference to the customer? If the customer pays ¾ cent per lamp hour and a lamp burns 600 hours, he pays for the energy consumed for that lamp during its life $4.50, and as light is the only product that is useful to the customer, a difference of 20 per cent. in the amount of light obtained from two different lamps would be a difference in value to the customer of 90 cents. I have seen tests of different makes of incandescent lamps showing even a greater difference than that stated above.

I believe that it is a well established rule of business that those business enterprises are in the end most prosperous where the customers' interests are most carefully considered. I remember several years ago being informed by one who had made a study of the operation of a number of large central stations, that those stations that were the most liberal in their lamp renewals were the most prosperous. The use of a lamp that is inferior, I believe will always result in reduced profits to the station even if the lamp should cost nothing.

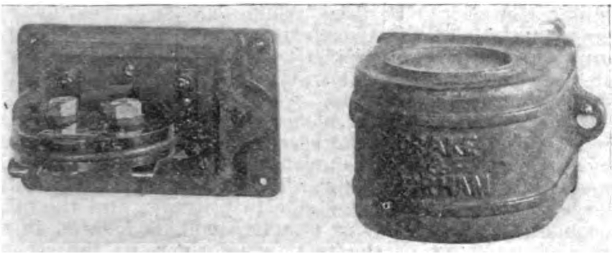
Large expenditures are made to obtain economical generating apparatus for the purpose of converting electrical energy into light and the device that must be depended upon to make the final conversion—the incandescent lamp—is often almost disregarded as a subject of careful study and investigation, although the result of the investment that has been made largely depend upon its operation. Its importance has been very appropriately referred to in an article in The Electrical Engineer, from which I quote: "The incandescent lamp is the very essence, the soul, of incandescent lighting, around which all other details of current production revolve as satellites to a central sun."

LIMA, O.—The Lima Railway Company now has a capital of $200,000. Mr. C. Currie, the general manager, informs us that it now has seven miles of road, regular gauge, sixty-six pound rail, with nine motor cars and two trailers, of the General Electric system. The other officers are: E. W. Moore, president; Edwin Stone, vice-president; superintendent, A. B. Lambe.

PROTECTIVE DEVICES FOR TRANSFORMERS.[1]

BY HERBERT C. WIRT.

THE transformer itself is a protective device, as it was introduced to permit the operation of incandescent lamps from high voltage circuits, with safety to human life. It has so well accomplished this purpose, that there are in operation in the United States four million 16 candle-power lamps, which are supplied with energy by means of transformers. A large number of transformers were introduced ten years ago, at a time when experience with electrical machinery, for operation on high voltage circuits was limited, and therefore many transformers were not properly constructed, and the failure of insulation may be laid in part to faulty design. The object of this paper is to call attention to several protective devices, which have been designed to render the transformer absolutely safe, and to suggest some precautionary measures that should be used by managers of central stations.



ELECTRICAL ENG'R N.Y.

FIG. 1.—CARDEW EARTHING DEVICE.

The cases which have occurred where the primary current has passed to the secondary wiring are comparatively few, but still sufficiently numerous to warrant the taking of greater precaution to prevent the possibility of fatal accidents. This subject is receiving careful attention on the part of the Underwriters, and many central station managers are looking into the question. Very little information has been published on this subject. Mr. William H. Merrill, Jr., electrician of the National Board of Fire Underwriters, has issued very valuable and interesting reports relating to fires of electrical origin, and during the past three years sixty-two cases have been mentioned by him, where the primary current has passed to the secondary wiring, and which have been considered only as a fire hazard.

The author then cited a number of cases of converter burn outs which had been investigated, all of which had occurred in converters not insulated with oil.

You will note in every case, the electrical discharge ignited the gas. It is easy to see the cause of this. The current passes from the secondary wires to the fixture, and then across the insulation in joint to the gas pipe system and to earth, forming an arc at the insulated joint, thus setting fire to the gas. If, however, insulated joints were not used, the path to earth from the secondary wires would be made easier, and probably a greater number of breakdowns would occur.

Note that all these accidents occurred in transformers that were not insulated with oil. Note also that many of these breakdowns occurred during a lightning storm, proving conclusively that most transformers are burned out, not by the alternator current, but by electrical discharges, due to disturbances of the atmosphere. It is, therefore, necessary to have a transformer insulated to stand such discharges, rather than to stand the alternator potential.

In the early days of transformer construction, the insulation was not designed to stand any definite voltage in excess of the alternator voltage. A transformer was supposed to be properly made if it did not burn out when tested on the standard current for which it was designed. Transformers of early design will just stand a high potential test of 3,000 volts.

The majority of transformers manufactured during the past year are made to stand a test of 5,000 volts between primary and secondary windings. One manufacturer has brought up the standard of insulation on his transformer sufficiently to stand a 10,000 volt alternating current test between primary and secondary.

The insulation of transformers should always be measured by high potential current, rather than by an insulation resistance test, in which a moderate voltage is used. Even 500 volts is not sufficient to properly test transformers, for it is easily seen that a small gap or break in insulation may be great enough not to be bridged by a 500 volt current, but the normal alternator potential of 1,000 or 2,000 volts will immediately start an arc across the defective insulation.

Oil should always be used to insulate transformer windings, as a high potential current will jump a space in air five times as great as in oil. The oil keeps the air from the coils, and prevents oxidation of the insulation material. The air in a transformer not insulated with oil, is heated and expanded from the coils, and when the transformer is cooled, air containing moisture can be drawn into the coils.

A number of automatic devices have been designed to be connected to the secondary wiring of transformers, so that in event of the high tension primary current passing to the secondary wiring, it will be automatically connected to the earth, thus preventing any danger of a shock, or the possibility of causing a fire. The most prominent devices are those designed by Prof. Elihu Thomson, in this country, and by Major Cardew, electrical adviser of the Board of Trade in England.

The Cardew earthing device, Fig. 1, consists of two metal plates, separated and insulated from each other by ¼-in. air space. The plates are held in a horizontal position. A thin strip of aluminum foil, about 3 inches long and ¼ in. wide, is flexibly attached at one end to the upper plate, which is connected to the secondary wiring, and the other end is supported near to, but normally not in contact with, the lower plate, which is connected to a good ground. If a difference of potential of about 300 volts exists between these two plates, the aluminum foil is attracted to the lower plate and will remain in contact with it until the primary fuses are blown. This, therefore, automatically grounds the secondary whenever there is a difference of more than 300 volts potential between secondary wires and earth.

Several thousand of these devices are in use in England, as such apparatus is required by the regulation of the English Board of Trade.

On the three-wire system, the device is connected to the neutral wire. With small transformers it is connected to only one side of the secondary circuit, and with large transformers one is placed on each secondary wire. It should be mentioned that most of the primary wires are run underground in England, and the transformers are not, therefore, subjected to atmospheric discharges of electricity.

Prof. Elihu Thomson has invented several protective devices. The "film cut-out," so called, is quite similar in its action to the Cardew earthing devices, the only difference between the two being that the plates are separated by a thin film of paper, which is pierced by a potential of 300 volts, making a good connection, and thus permitting the primary fuse to melt. The device was first commercially used in 1890. The transformers at that date were so poorly insulated that it was found that the primary current passed to the secondary wiring so frequently their use had to be abandoned.

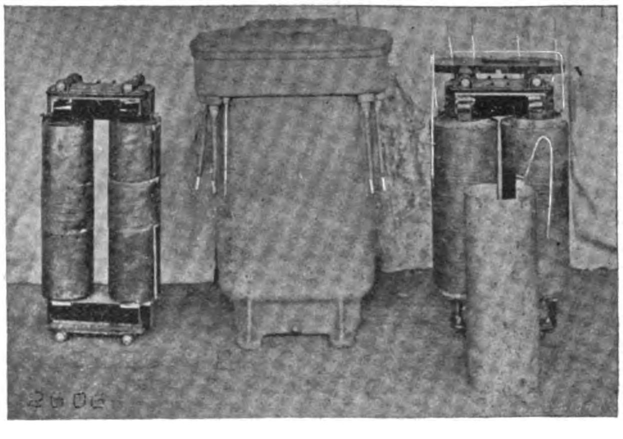


FIG. 2.—GROUND SHIELD OF TRANSFORMERS.

Prof. Thomson's most prominent protective devices, developed in 1885, are known as the ground shield and grounded secondary. The ground shield, Fig. 2, consists of a sheet metal covering, placed in the transformers between the primary and secondary windings in such a way that it is impossible for any current to pass from the primary to the secondary windings without connecting with the metal shield. The shield is connected to a good ground, and therefore the primary current will not pass to the secondary wiring. The grounded secondary is shown in Fig. 3.

The most notable installation in this country of transformers with ground shield, is at Elizabeth, N. J. The transformers were constructed to stand a 10,000 volt high potential test from primary to secondary, and 5,000 volts from primary to ground shield. There are 225 transformers installed, and they have been in operation about three years, and the total number damaged by lightning has been seven.

---

[1] Abstract of a paper read before the Northwestern Electrical Association, Jan. 20, 1897.

The lines are protected by sixty line arresters and an equipment of station arresters of an approved type. The engineer reports that whereas the ground shield seems to create more of a tendency for the lightning current to burn out the transformer, it has prevented the primary current connecting with the house circuit and thereby endangering life.

In the grounded secondary system, the house wiring is permanently connectly to ground. This connection may be made from either side of the secondary, or carried from the middle point of the secondary winding in the transformer. In the latter case there is a difference of half the potential of the secondary system existing between the secondary wires and the earth. If only one of the secondary wires is grounded, there exists a difference of potential between the earth and the other secondary wire equal to the full secondary voltage. These systems, therefore, are objectionable from an insurance standpoint, as it has not been thought desirable to have the secondary system grounded, on account of the danger of leakage of the secondary current.

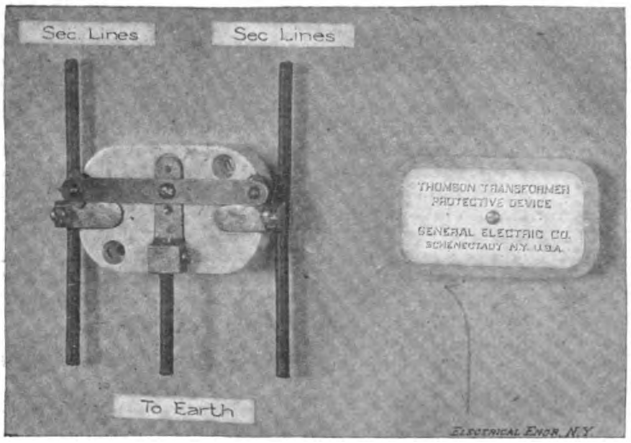

FIG. 3.—THOMSON PROTECTIVE DEVICE FOR TRANSFORMERS.

The film cut-out and Cardew earthing device have an advantage over permanently grounding the secondary, as there is less liability of a leak from wires to ground, except at the time when the devices are short circuited.

A large installation in the town of Suncook, N. H., has been in operation during the past year, with a grounded secondary. The installation consists of 2,000 lights, located in several mills, and about 500 in the town. The generating station is located six miles from the town and mills; primary 2,500 volts. A three-wire secondary system is used—100 volts on each side. The neutral wire is grounded. The lines are well protected by lightning arresters, which were not of the short gap type.

Two transformers have burned out, but after a careful examination, the conclusion was arrived at that one of the transformers at least had been injured by water, as the transformer box had been opened during a heavy rain storm. If the short gap lightning arresters were used, there would be less liability of the transformers burning out.

It will be seen from the above, that the lightning arrester is a very important protective device, as we must depend upon arresters to conduct the lightning discharges to the ground. If we did not use arresters, it would be almost impossible to construct a transformer that would not burn out. We might use a protective device, to prevent any danger from the current passing to the secondary wiring, but we would frequently have transformers burn out. Arresters have heretofore been designed solely for the purpose of preventing the dynamo current maintaining an arc after the passage of the lightning discharge. A new arrester has been designed, which affords an easy path to ground for the lightning current.

A careful test of the various arresters on the market to-day shows that 1,000 volt arresters require from 3,000 to 4,500 volts, and the 2,000 volt arresters require from 6,000 to 9,000 volts potential to cause the current to pass from line to ground across the gaps.

The necessity of a short gap arrester has undoubtedly been known to many experimenters, but until recently no method was devised to permit the short gap arresters to be used on high voltage alternating currents. We are pleased to say that an arrester has recently been designed so that but one gap of 1-32 inch is required for a 1,000 volt arrester, and two gaps of 1-32 inch each for a 2,000 volt arrester, requiring 2,000 and 4,000 volts, respectively, for the current to pass across the gaps. It is believed that these arresters will afford protection to transformers provided with insulation that will stand a 5,000 volt potential test. This arrester consists of large metal cylinders, separated by short air gaps in series with which is placed a low non-inductive resistance to limit the current at short circuit. The arc is cooled so that upon the reversal of the alternating machine current, it is extinguished.

Transformers having defective insulation between primary and secondary should be immediately disconnected. The only way to discover a transformer of this kind is to make insulation tests, and therefore it is apparent that periodical tests should be made of the insulation between primary and secondary of all transformers.

As a high potential current is necessary, a small step-up transformer should be used, which can be carried around to the points where the transformers are located. This transformer should have a capacity of at least 2 kilowatt for testing transformers of 30 kilowatt capacity and less, in order to supply the capacity current.

In making a test, the house transformer is disconnected from both the primary and secondary wires. The primary of the test transformer is connected to primary lines, which are energized by the alternator. The secondary is connected to the house transformer; one side to primary, and the other to secondary. A rheostat, or re-active coil, is located in series with the primary of the test transformer, so the secondary voltage may be varied between the limits of 2,500 to 10,000 volts. A fuse should be located in the primary circuit, to open when the insulation is punctured.

The high potential current should be applied for 60 seconds, and any transformer that will not stand a 3,000 volt test should be scrapped. It will be found that the transformers that have poor insulation, also have very high core losses, and are not economical, for in many cases it will be found that the revenue obtained from the transformer will not be sufficient to pay for the coal used in generating the current to supply the iron core loss. Therefore, it will be most economical to scrap such transformers.

This test should be made as frequently as possible, and at least once a year. When making this test, the secondary should be connected with the iron core, as this acts as a condenser and a high potential current would be generated in secondary wires, which would burn out the insulation between secondary wires and core.

Transformers are not generally tested for leakage between primaries and secondaries, and as they are isolated on the line, there is no means of testing for leakage at the central station without extra wires. It is apparent that it is necessary to make frequent tests of this kind. An interesting method of testing transformers has been in operation at Great Falls, Montana, for the past two years. The secondaries of half a dozen transformers are connected to a common test wire, Fig. 4, which is run to the central station, and tests are frequently made there between this test wire and each side of the

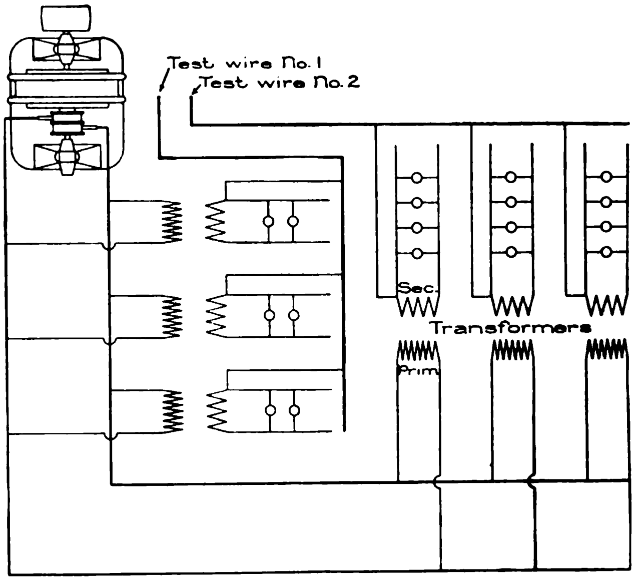

FIG. 4. CONNECTIONS OF TRANSFORMER TEST WIRES FROM CENTRAL STATION.

primary circuit. The normal primary current of 2,080 volts is used for testing. Since using the test wire, the system has been operated without accident and a great saving of time has been effected by means of the test wire. It would seem that there might be many cases where this system would be of advantage.

A fatal accident can only occur when the following connections are made: 1. A ground on one of the primary wires. 2. A leak between primary and secondary on the opposite side of the system on which the ground is located. 3. A person in circuit with the secondary and ground. As the majority of lamps are installed in locations where it is impossible to get a connection to ground, many chances of receiving fatal shocks are avoided. If the primary lines are kept free from grounds, no shock can be obtained. It is, therefore, essential to use the most approved appliances at central stations for indicating grounds on primary wires.

The most common ground detector in use at present consists of a transformer, the primary of which is attached to the line to be tested and the ground. The secondary winding of the transformer is in circuit with an incandescent lamp. The ground is indicated by the brilliancy of the lamp. This seems to be a very crude method of indicating grounds, as there is an opportunity of error, and the detector is connected only at stated periods. It has been said that alternating lines always have a slight ground, as the ground lamp always burns at a dull red. This is due to the capacity effect of the lines, and not to actual leakage of primary current.

The transformer system can be greatly improved in the following manner:

1. There should be used at the station and on outside lines, short gap lightning arresters that will permit the passage of the current across the gaps, before the insulation of the transformers will be broken down.
2. Transformers operated on 3,000 volt circuits or less, should be constructed to stand a high potential test of 7,500 to 10,000 volts for 60 seconds between primary and secondary windings.
3. A safety device should be used in connection with transformers, that will prevent any difference of pressure in excess of 300 volts between secondary wires and ground.
4. Transformers should be filled with oil.
5. Transformers should be periodically tested for insulation between primary and secondary, with high potential currents.
6. A ground detector which will positively indicate a leakage of current from primary wires to ground should be used at the central station. It should not be affected by the capacity effect of lines and it should be designed to be left permanently in circuit.

ON MUNICIPAL AND OPPOSITION OWNERSHIP.[1]

BY H. L. DOHERTY.

Your committee finds a large field of work, and the association probably acted none too soon in recognizing the growing sentiment of municipal ownership. The municipal wave passing over this country is widespread, and numerous central stations are threatened. Each municipal plant installed incites the neighboring city to do likewise, and no central station can consider itself safe from this evil. Investigations warrant the statement that this is the most important subject for the attention of central station men, and every member of this association should feel responsible in aiding the work of demonstrating to the public that the municipal scheme is not practical, and the majority of municipal plants if carefully investigated will prove to be gross failures.

We were instructed to confer with the electrical manufacturers and obtain their promise of co-operation in preventing the misrepresentation as to cost of installation, operation and results obtained from municipal plants. All of the large manufacturers claim to co-operate with us, but in spite of their statement to that effect, they are not all supporting us. The opportunity offered them to hide behind the efforts of electrical engineers, makes it possible for them to agitate and abet the installation of municipal plants without openly showing their hand. We therefore think the best evidence of good faith they can furnish the central station men of the country is to let this branch of the business alone. We therefore suggest that the committee carrying on this work be instructed to report at each meeting the number and locations of municipal plants installed, and the names of the manufacturers furnishing the steam and electrical apparatus. Persons in the electrical business who guide their opinions by observations of municipal operations cannot honestly claim that municipal ownership is apt to prove beneficial to the municipality, and hence, the advocates of this scheme must be regarded as either lacking the ability of observation, or else self-interest prompts their motives. All advocates of municipal ownership must be regarded as the natural foes of central station men and others who desire the welfare of the business as a whole. Central station men should patronize their friends, and they should satisfy themselves that their manufacturers are not aiding and agitating the establishment of municipal lighting plants and thus wrecking the property of some fellow central station owner.

We endeavored to obtain the co-operation of the National Electrical Association, but were unsuccessful. We regret the fact that they cannot see the advantage to be gained by both by a consolidation of our interests as we are each endeavoring to accomplish the same end.

We have also written the General Electric Company, the Westinghouse Company, and the Fort Wayne Corporation, requesting to know the number of municipal plants established throughout the Northwest during the past year where private stations already existed, and also the names of the manufacturers furnishing the steam and electrical apparatus. We hope to have their replies in hand so we may incorporate them as a portion of this report.

We have had four appeals from central stations which were threatened with municipal ownership. As this is a public report, we think it well to withhold the names of all but one of these, which is Negaunee, Mich. In this case we did all possible to protect the central station owners from having their property rendered useless to them, but the matter has progressed to such an extent where apparently nothing could help them except the courts, and we understand that the matter is now pending a decision of the Supreme Court.

At Madison, Wis., the establishment of a municipal plant was attempted, but failed to be erected as sufficient votes could not be secured in the council to warrant the issue of bonds necessary to cover the purchase price of the plant. However, they went as far as they could in the matter; accepted the bid of the Fort Wayne Electrical Corporation for a plant complete, and later on gave a second reading to an ordinance granting the Fort Wayne Electrical Corporation a contract for putting in a plant on the installment plan, as the lack of funds was all that prevented its installation. This last ordinance was never brought up for final passage, as it was apparent that the parties interested could not secure sufficient votes for its passage, and the city made a one year's contract with the local lighting company.

We have endeavored to investigate the results obtained in the municipal plants already established, but find that this cannot be properly done except by sending a capable representative to these municipal plants. We have written for regular city reports, and have sent out blanks requesting answers to a number of questions asked. We find that in the majority of instances, the expense report as covering the cost of electrical lighting does not cover such cost, as is evinced by finding electrical light expenses charged under separate heads, and in but few instances does the city figure anything against the plant for interest, depreciation, taxes, water rent, office rent, management, fire insurance, employers' liability insurance and general risk. It is needless to say that without including but a portion of the expense of conducting an electrical light plant, they can send out reports that look very inviting to other cities who are paying a fair rate for lighting their streets and houses.

In regard to the information gathered, we consider it advisable to hold this as confidential for the use of our members and such central station men who are threatened with this form of opposition. By making the facts public nothing can be gained, and it allows the advocates of municipal ownership to avoid quoting the plant that they know we have evidence with which to disprove their assertions. We also think it best not to disclose our manner of obtaining information on the failure of municipal plants as this would give our competitors an equal footing provided they have not already availed themselves of the same avenue of information.

POWER TRANSMISSION DATA WANTED.

Mr. Charles Renwick, C. E., Government Engineer, Montego Bay, Jamaica, West Indies, wishes to receive catalogues and data relating to the development of power from water and the transmission of that power to motor pumps which can raise the water from the reservoirs into which it flows after reaching the plains from the mountains. Mr. Renwick will be glad to receive full information that will enable him to decide on the feasibility of such work in the island, which has well watered mountains with numerous towns in the adjacent plains.

---

[1] Report of a committee of the Northwest Elec. Ass'n.—Abstract.

SOCIETY & CLUB NOTES

FIFTH ANNUAL CONVENTION OT THE NORTHWESTERN ELECTRICAL ASSOCIATION AT MILWAUKEE, WIS.

THE convention was called to order at 11:40 a. m., Jan. 20, at the club house of the Pfister Hotel, Milwaukee, Wis., by Mr. H. C. Higgins, second vice-president, the president, W. B. Baker, being absent, owing to illness.

Secretary T. R. Mercein read his report, which was highly praised by the members.

The programme committee then presented its report, which was adopted unanimously.

The secretary then read a list of twenty-eight applications for membership in the association; all applicants were elected. Various communications were read offering facilities for the next meeting of the association.

On motion Messrs. Bebell, Copeland and Hanley were appointed as committee on adjustment of secretary's salary.

Mr. F. S. Terry, of Chicago, then read a paper on the subject of "Incandescent Lamps."[1]

A vote of thanks of the association was unanimously tendered to Mr. Terry for his excellent paper.

On motion the representatives of the press were invited to attend the banquet.

WEDNESDAY AFTERNOON SESSION.

The convention was called to order at 3:50 p. m. by Second Vice-President Higgins. The Electrical Exchange of Chicago, and the Charles E. Gregory Company, of Chicago, were elected to membership.

A paper was read by Mr. H. C. Wirt, of Schenectady, N. Y., on "Protective Devices for Transformers."[2]

MR. F. McMASTER inquired how the grounding core is arranged so that there are no losses from induction in the protective device.

MR. WIRT: The shield is a sheet of copper and the ends are insulated so that there is no current passing in the shield. If you made a complete loop around the core, of course there would be current wasted in the shield.

MR. S. PIERCE inquired what kind of a device he recommended to have permanently left in the circuit in order to show the ground, which would not cause trouble in some other way.

MR. WIRT replied that a static instrument could be used something like Lord Kelvin s static voltmeter. Each line would form a coil and the capacity effects of line would balance and if there were a leak the difference would be measured by an indicator. In the course of six weeks, he said, such an instrument would be on the market.

PROF. W. M. STINE inquired if there were any scientific connection between the high core loss and the low insulation in the second wire.

MR. WIRT replied that there was no scientific connection between the two. He merely wanted to make it as easy as possible for the gentlemen to take off their old transformers. (Laughter and applause.) In the case of a transformer supplying his house, which has been in operation 16 months, Mr. Wirt had taken the bills for 16 months and measured the core losses and found that the central station had made just enough money to pay for fuel for core losses, to say nothing of the energy lost in supplying the lights.

MR. CARYL D. HASKINS thought that there might be some connection between the poor insulation and core losses. Poor insulation might result in heating which might very readily break down such insulation, as is used in insulating the plates of the core one from the other, and that would cause increased current losses; he thought Mr. Wirt's point very well taken.

A paper on "Insurance as Affected by Electrical Construction," was then read by Mr. George S. McLaren, of Milwaukee.

MR. P. H. KORST inquired if when electric light is used it was considered a better risk than kerosene lamps.

MR. McLAREN considered correctly installed electric light equipment as far better in every way than a kerosene lamp outfit. If a building had had its premium rate increased on account of the use of kerosene lamps and then they are removed and a correctly installed electric light plant put in, the premium rate would be correspondingly reduced. No increased rate was added for the common use of gas. First-class electric light installation was the safest there is. There was no real difference in the rate.

Mr. McLaren, in reply to a question said that the insurance people did not consider the use of water proof wire inside of buildings at all. Rubber covered wire, with good braid, was the only satisfactory insulation. He believed the correct place for cutouts was not in a canopy, but in a properly made cabinet so arranged that one could tell just where a difficulty lies in case one arises. Mr. McLaren stated further that in some special factory buildings where coal oil lamps are used in Milwaukee, there is an increase in rate, but where they are taken out of such buildings and electricity put in, rates are reduced. But in general business buildings there is no rate added at all for the use of lamps of any kind.

MR. F. C. McMASTER thought it would be for the benefit of all concerned if those engaged in construction work were examined and licensed like plumbers.

MR. McLAREN thought the only way to get at that would be for the association to get an act passed by the legislature requiring an examination for all electrical workers. He thought such a law could be passed.

MR. GEORGE L. THAYER stated that the insurance inspectors of the eastern district of Iowa last year sent a man out on a tour of education, and he had with him a draft of an ordinance prepared, which he asked all central station men to see that the city council put through, and the ordinance provided that all contractors doing wiring should take out a license and should pay a fee of $20 a year for their licenses; and there were several different schemes for the examination of the contractors. It depended upon the size of the town and the amount of wiring done. Through the adoption of that scheme they were getting a better system of wiring done throughout the territory.

MR. H. L. DOHERTY thought that might be a very nice thing for the insurance companies, but it certainly curtailed the rights of central stations, which, as things stood now, could have the work done by any one and could protect themselves, by refusing to turn on current on poor wiring.

MR. DEBELL was of the same opinion.

MR. McMASTER agreed with what had been said, but in a large number of towns the stations were selfish in a way and would not, if they could possibly help it, allow a man to go in and do any work.

MR. DEBELL thought that any central station would be working very much against its own interest if it adopted any arbitrary measures of that kind to keep out any particular wiring man. He did not think that legislation or anything else would help such a station at all.

MR. CUTTER believed that the association should not approve any action looking to legislation, as contrary to its best interests. They already had disturbing elements enough. They had got the insurance underwriters telling them what to do, and now the politicians were to tell them what to do. (Applause.)

PROF. JACKSON: One aspect of this affair strikes at the root of the matter, and if properly considered by the central stations, would practically remove most of the trouble. I have found through all this State and all through the Western States, and largely in the Middle States, that not only do a large proportion of the contractors for wiring in small towns at least know very little of the details of the underwriters' code, but even the employés of the central stations that have the inspection of the wiring after the contractors put it in, knew little of the code in many cases. If that code were thoroughly drilled into the minds of the contractors by central station people and into the minds of the employés of the central stations, I doubt very much whether we would have much complaint regarding the dangers of electric wiring. The trouble is largely due to the lethargy of the central station managers themselves, though I do not want to attack them.

MR. PLINY NORCROSS thought that further discussion of the subject would be useless. The fellows that were on their trail were the insurance companies and they did not let up on them. Twelve years ago the only wire he adopted was the underwriters' wire, and more miserable wire was never invented. (Applause.) The underwriters' rules of five years ago were no more the rules of to-day than black was white.

MR. COPELAND: I am interested in a plant (not electric) on which sometime ago I had an insurance with a premium rate of 3 per cent. The insurance company informed me that if I would change from a shingle roof to a metallic roof they would reduce the insurance rate; and if I would put in water sprinklers they would make a further reduction; that if I would put in a larger supply pipe they would make a further reduction. My rate, however, is still 3½ per cent. (Great laughter and applause.)

MR. BEAN inquired why the insurance companies charged as much where coal oil lamps were used as they did where good wiring is done..

---

[1] See page 111.

[2] See page 113.

MR. McLAREN replied that in certain classes of buildings they charged more if lamps were used, but not in all buildings. If they were charging a rate of 10 per cent. for using a coal oil lamp if you took out the lamp and put in an electric plant they would take off the 10 per cent. But in many cases they did not charge for the lamps. If they are using oil lamps they may be only using a few and the insurance company might not consider the matter dangerous to a sufficient degree to increase the rates in all cases. Matches were dangerous, but they did not charge for the use of matches in buildings.

MR. R. F. KOUNTZ stated that he began in the early days to use underwriters' wire as recommended by the New York and Philadelphia Board of Underwriters, and had not changed yet, and did not know that he ever would. (Applause and laughter.)

It was moved and seconded that the statistics referred to by the secretary in his report as being obtained from the various central stations be printed in pamphlet form and a copy sent gratis to each central station that had furnished the information and to each member of the association, without names, but with a key. Unanimously adopted. Mr. Kountz contributed $5 toward the expense of printing the pamphlet.

MR. DOHERTY, chairman of special committee on municipal ownership then read the report of the committee.[1]

MR. DOHERTY stated that he had essayed to obtain the co-operation of the National Electric Light Association, but that correspondence he had had with that end in view had not turned out satisfactorily.

MR. COLEMAN then continued the report of the committee on municipal ownership of lighting plants.

MR. W. J. BUCKLEY said he had been identified with the Fort Wayne Corporation ever since it was started, and he was very glad indeed of an opportunity to say that the Fort Wayne Electric Corporation, as well as himself, took the position that municipal ownership was a fallacy and a failure; that a majority of all the municipal plants that had been erected were failures in that it had cost the cities that had built them more money to operate per light than the local companies offered to give them light of equal service for. It was not in the province of this association, nor was it in the province of the central station manager whose station and whose property were jeopardized by this municipal ownership idea to attack the manufacturers of apparatus or to directly look to the manufacturer of apparatus for the cure of the disease that threatened them. A city wishing to buy a plant usually wanted arc lights. In that case they could get bids from but three companies, the Brush Electric Company, the General Electric and the Fort Wayne. If they wanted incandescent lights then of course they must include the Westinghouse Company. He was sure that prices on apparatus were such, and the profit in their business was so small, that they could not afford to do anything that was so diametrically opposed to the interests of their various organizations as to sell to any municipality that was going to deprive them of the revenue from the central station men. Mr. Buckley suggested that a central station manager ought to become acquainted with and cultivate the city council men. He believed that Massachusetts had set the best example of any State in the Union for the handling of this question. The various central station managers there combined together, formed a purse, sent their representatives to the legislature, and the legislature made an enactment whereby any municipality that wishes to purchase its own electric lighting plant must first receive and consider the proposal of a local company for such parts of their apparatus as may be applied to a city plant. If they refuse that proposition, or do not accept it, stating that the price is not right, then the city selects an arbitrator, the central station man selects an arbitrator, and those two fix the price, and the municipality is compelled by this enactment to pay the local lighting station the price fixed by the arbitrators for such part of their apparatus as may be utilized. He advocated the following of a like plan in Wisconsin.

MR. COLEMAN: The fact is, this business itself is responsible for the distrust that has come upon it among the people, because the installation of some of the plants through this country has been most stupendously fraudulent. I know of those things to my own personal knowledge, as an attorney, and I can tell you of a plant where not more than $50,000 was invested, which plant was bonded for $400,000, stocked for $400,000, and its notes were out for another $100,000. (Laughter.) I say we are at fault in this business, and we have got to put this matter before the people in the right way, in a clean handed way, in an open way, as a business proposition, and not sneakingly showing them that we have got something to cover up and intimating, "We will give you Hail Columbia if you don't do it." If the people understand thoroughly the exact situation, how much expert and careful work it takes to make the two ends meet, to say nothing of paying dividends, then, gentlemen, we are not going to have a great deal of trouble in regard to this municipal lighting business. Let us clean our hands and show them clean and keep them clean to the people, and this municipal lighting business will be a success. (Applause.)

MR. BEAN: The gentleman remarked that we ought to get better acquainted with city councils. With all due deference to him, if reports are true, I do not want to get acquainted with common councils like the Fort Wayne Company has. (Applause.) We do not fool with councils that way. Our propositions are plain and clean cut and we do not want to get in with councils, because we all know them in the cities and have a personal acquaintance with them before they are elected. (Laughter and applause.)

The report of the committee was referred to the directors with power to authorize and furnish means for the committee to carry on their work on the lines that they had been following so far.

MR. F. S. TERRY suggested that the members write the Gas and Electric Light Commission of Massachusetts, at Boston, for their report containing interesting matter in regard to regulating competition, etc.

The committee on secretary's salary recommended that the salary of the secretary for the ensuing year be fixed at $150, and that $50 in addition to that amount be allowed as extra compensation for the last year's work.

The association then adjourned to meet January 21, 1897, 10 a. m., same place.

In the evening the convention assembled to listen to a lecture on and demonstration of "Röntgen Ray Phenomena"[1] by Mr. Caryl D. Haskins.

THURSDAY MORNING SESSION.

The convention was called to order by the second vice-president, Mr. Higgins, in chair.

Mr. Pierce, of Negaunee, Wis., was then requested to address the convention on the subject of the municipal lighting plant at Negaunee.

MR. PIERCE: I live in the Upper Peninsula, which Wisconsin rightfully claims as part of the State of Wisconsin, and in which place the municipal ownership idea is prevailing somewhat. As regards the plant in Negaunee I will give you the facts of the matter and then you can see who is to blame. About a year ago Mr. Pingree made a visit to the Upper Peninsula and came to Negaunee. Mr. Kirkwood, mayor of Negaunee, is a great admirer of Pingree, and thought by following out Pingree's Detroit example in Negaunee money would be saved for the city. Through Pingree they engaged Mr. Rae who was to give them an estimate of what it would cost to operate 30 street lights and 1,000 incandescent lights. The figures he gave were somewhat of a fairy nature, that is, they were to run 30 street lights on a dark night schedule and 1,000 incandescent lamps (that is, what they would use regularly) on less than 300 tons of coal per year (!). This was of much interest to the council and they thought that by putting in this plant right away, that is, providing they could put it in for less than ten thousand dollars, they would go ahead, and his figures pointed out where they could make 60 per cent. profit on the plant.

Mr. Pierce then detailed the reasons why several of the councilmen were opposed to the electric light company, all on purely personal grounds, and then continued. At a meeting they discussed the subject and came to the conclusion that they would advertise for bids. Bids were advertised for, and there were three or four bids. He thought the Fort Wayne, the Westinghouse and the Western Electric Companies all bid on the electrical apparatus. There was only one bidder for the engines, which was the Russell Company. The contract was let by the three hostile aldermen with whom they had had these difficulties. They were the members of the electric light commission and they let the contract to the Fort Wayne company through Mr. Rae's suggestions.

They went to work in such a way that the people throughout the town were somewhat disgusted with their operations, and there was an injunction got out on the ground that they were spending other people's money without the consent of the tax payers of the town. The injunction was made permanent and that required an election in the State of Michigan. In the council at the present time there are only two tax payers.

A VOICE: The same as elsewhere.

VICE-PRESIDENT HIGGINS: There is none in ours. (Great laughter.)

---

[1] See page 115.

MR. PIERCE: After the election we found out that we had lost and then proposed to bid on the plant ourselves, and the General Electric Company said they would bid. We thought that it was right that if the municipality was determined to put in this plant that we ought to have some recognition, that is, that they should buy our machinery, as we would have a fair plant lying idle. There was a meeting of the council after that in which they decided to readvertise for bids. In the second asking for bids there were three bidders, ourselves, the street railway company, the Fort Wayne Company and the General Electric Company. We bid on a complete plant. The Fort Wayne Company bid on the electric apparatus and the Russell Engine Company bid on the engine; and they were somewhat combined, I guess. The General Electric Company bid on the electric apparatus alone. Our bid was $2,000 lower than the Fort Wayne's, that is, the complete bid. The General Electric Company was about $250 lower than the Fort Wayne bid for electric apparatus. There was an executive session held, in which Mr. Rae was asked to take part. Nobody else was there except the aldermen and Rae, and we could easily tell that the thing was all cut and dried before they went upstairs. But when they came down everything was let to the Fort Wayne Company the same as usual, they being the highest bidders. (Great laughter and applause.)

After these bids were let, another injunction was gotten out on the grounds of fraud, illegal election and that the outlying lands were not properly taxable for the purposes of municipal electric lighting. The case was tried at the circuit court and the injunction was dissolved, but the matter has been appealed to the supreme court and only a few days ago the supreme court granted a stay of proceedings, which really means another injunction from the supreme court. The point that they are bringing out is that of the outlying lands not being taxable for the purposes for which they were taxed. That point is this: The plans are drawn up, the lights are located and the city of Negaunee in order to raise taxes enough for the support of the city government is obliged to annex more property to the city. Some of this property is at least two miles from the city; and these people objected to paying the tax for electric light purposes. So that is the way the matter stands at the present time, and the case is to be heard on February 2. A few days ago some of the Fort Wayne machinery arrived. And a few 15-foot poles. (Laughter.) There were a few 30-foot poles, I think, about 6 or 7, and the rest of them were 15-foot poles. The plans and specifications call for 35-foot poles, while we have put in in our plant 40, 45 and 50-foot poles. On the way up the Fort Wayne representative was given a note by Mr. Rae, asking the city council to pay over to the Fort Wayne Company half of the contract price, which was $3,250; that everything was O. K.; and it was signed by the engineer. The city council refused to pay it, and in some of their discussions they have come to the conclusion that Mr. Rae and the Fort Wayne Company are working in conjunction with each other. Every thing shows that. I think from what I have seen and heard up there that they are getting somewhat tired of the engineer right along from the way he is acting in regard to the money and other things that are happening there right along.

MR. SCHUETTE, of Manitowoc, then read a paper on the "Defects and Dangers of Municipal Ownership."

Mr. Schuette added, after concluding the reading of his paper, that at the present time as the law stood, any city in Wisconsin could build its own municipal plant, operate it and sell light to private individuals; but not unless the owner of the existing plant did not want to sell his plant; that is to say, that they must condemn those plants if there are any; but if the owner is not willing to sell then they can build a plant in opposition to him. He advocates assessing electric light companies 10 cents per kilowatt capacity, to maintain a representative at the State Capital to watch legislation.

The election was then proceeded with and resulted as follows:

President H. C. Higgins, of Marinette, Wis.; first vice-president, G. L. Cole, of Beloit, Wis.; second vice-president, J. H. Harding, Laporte, Ind.; secretary and treasurer, T. R. Mercein, Milwaukee, Wis.; directors, Messrs. Debell, Rand and Bean.

A paper was then read by PROF. W. M. STINE, of Chicago, on "Safety Devices for Electrical Circuits."

Prof. Stine added that if one buys from a supply house a spool of fuse wire stamped 15 amperes, that really meant nothing except that for four inches in length in that sized wire that would be the fusing point of that wire; but that was not a commercial length. What should be the duty of a supply man in this matter? He should accompany that wire with such a curve as that indicated in the diagram embodied in the paper, or the results indicated in a table. Since publishing his first paper on this subject, a fuse company in Chicago had undertaken to do this. PROF. KLINE also briefly discussed the paper.

The selection of a meeting place for the next convention was left to the Board of Directors to report upon later.

The meeting then adjourned until 2 p. m.

THURSDAY AFTERNOON SESSION.

MR. SCHUETTE again brought up the subject of the association being adequately represented at Madison, to guard its interests in the legislature, and after some debate a resolution was passed that a committee be appointed and the necessary funds for them to carry on this work be raised by the Ways and Means Committee by assessing the stations in the State of Wisconsin pro rata by kilowatt or otherwise, sufficient to cover the expense necessary.

After a lengthy discussion as to the work of the Protective Committee in States other than Wisconsin, MR. KOUNTZ moved that the Protective Committee under the laws and regulations of the association attend to the legislation within its jurisdiction, and that the plants in the jurisdiction be assessed a reasonable sum to defray expenses, and that it be left to the judgment of the committee as to what portion should be expended in each territorial jurisdiction.

La Crosse was then selected as the next meeting place. Five applicants for membership were acted upon favorably.

The secretary then read a paper on "Gaseous Fuel as a means of Cheapening Electricity," by N. W. Perry.

Mr. W. W. Low, of Chicago, then read a paper on "Electrical Supplies." Mr. Low added during the reading of his paper that in regard to slow accounts, 75 per cent. of the central station accounts of that character were municipal accounts. Some were very prompt, but the majority were slow. He believed that between 30 and 35 per cent. of the orders that they received (and that included traveling mens' orders) have to be held until further information is secured, because the orders are not given explicitly.

Mr. George Cutter, of Chicago, then read a paper on "Electric Heating."

MR. LORD stated that in his water power plant at Waupaca he might increase his profits largely, if he could get a heating load on the plant which is now completely shut down at daylight, letting 250 horse-power run to waste all day. A discussion was also had on the advisability of utilizing and distributing exhaust steam for heating purposes. MR. THAYER described the Webster system of exhaust steam distribution.

MR. DOHERTY: We have one associate member on our committee who last year obtained eleven new members for the association. I refer to Mr. Christie. Mr. Mercein has also mentioned the matter in his report, but I think it is no more than proper to acknowledge Mr. Christie's services in some way.

The secretary then moved that a vote of thanks be extended by the association to Mr. S. E. Christie, of Chicago, for his zeal in securing new members for the association.

MR. DOHERTY suggested the establishment of what might become the "question box" from which questions might be taken to be discussed at meetings.

After a brief discussion on miscellaneous topics the convention adjourned sine die.

MUNICIPAL OWNERSHIP OF ELECTRIC LIGHTING PLANTS.[1]

If the municipal lighting movement is right, we gain nothing by kicking, but will be injured by reaction. If that movement is without proper foundation it must be met by facts and figures.

We have much to contend with in dealing with the people. They have good reason to be cautious in dealing with electrical matters. Probably the majority of electric plants today were installed on a fictitious basis. With the capital stock much above the actual investment and bonds issued to a vastly larger amount than the real investments.

This was the electric era of promoters. And was quickly followed by the era of assignments, foreclosures and receivers. The former fraudulent transactions have been shown up, the impression being left upon the public mind that electric light can be produced at a much less figure than is paid for it. We who are in the business know how far they are out of the way.

The third era of the business is now on, and the bondholder, the creditor, the purchaser at foreclosure sale and the honest investor are now on deck with the full understanding that only honest work will bring good results.

---

[1] Supplementary Report, by Mr. E. Coleman, Northwest Elec. Ass'n.

We must meet the agitators for municipal ownership with open hands, and when they think judicially on all sides of the question the agitation will cease.

Water works corporations and lighting corporations are from their very nature quasi-public corporations. They cannot operate without a franchise from the municipality. That franchise when accepted becomes a contract between the city and the corporation, and carries with it obligations binding both. The city signs it for two reasons: First, that private parties shall put in the capital and produce the electric current to light the streets and public buildings, and, second, to light the houses and business places of the citizens.

If the company does its work well and in good faith, it has a right to expect good faith from the municipality. The company pays its taxes, furnishes good light, and is a booming card for citizens to boast of. Is it equitable on the part of the city to enter the field against such a company and as a competitor to it, merely because with its help the city treasury has become plethoric and it can build its own plant?

On the other hand if the company, after receiving its franchise has only played the role of a leech, then the city fathers should cause its franchise to be judicially annulled and proceed to build its own plant, or to do what is better; contract with a reliable company to furnish the city and its citizens with equitable but living rates.

The latter procedure is worthy of all honest commendation while the former can best be illustrated by the familiar story in song of a faithful mother who had borne and patiently reared to manhood an ingrate son, who when he thought her of no further use to him sent her over the hills to the poor house.

Your committee does not give an opinion that the municipality either has or has not a legal right to thus destroy the value of the local plant. That question must be settled by the terms of the franchise itself. All will agree that it has neither the moral or equitable right to do so.

It is therefore certain that the municipality should not be given the power to put in plants, unless (1) the existing companies shall be bought out, or (2) their stock bought up, or (3) if agreement of purchase cannot be made, that process of condemnation be had under power of eminent domain as in railroads. While hardships might come to some, these methods would all be fair and equitable.

The remaining questions are these: 1. Is municipal ownership practical? 2. Will it be remunerative?

The office of a town or city is not to dig our potatoes, cut wood, or chop our hash, or to do any of the ordinary work of life, excepting of course to furnish lawyers with lawsuits—but its office is to do for all its citizens such work as individuals or corporations cannot do for themselves such as furnishing protection, building and maintaining streets and furnishing water and lights and the two latter can better be done by the quasi-corporation in most cases than by the city itself, and these franchises are given to these corporations to relieve the city of an additional swarm of blood-suckers—both political and personal. When once the additional crowd has fastened its fangs on the body politic there is no such word as "Let go."

In the financial phase lies the greatest objection. 1. A commission (non-partisan, of course) must be appointed. 2. A manager must be hired. 3. An expert electrician must be had. 4. Duplicate machinery must be put in, for commissions, boards of experts and common councils, can keep no pace with electrical currents, machinery or men. 5. If the public plant furnishes electricity for private consumption the sucker citizen will forever be hounding the manager for rebates political, rebates special and rebates on general principles. 6. The manager and manufacturer will put their heads together to fool the board and the public bleeds at every pore. 7. If the ever alert central plant manager cannot keep pace with the rush of improvements where will the foregoing crowd be left?

Our hasty conclusions are, then, as follows:

1. That legislatures should grant no powers to municipalities to erect and maintain lighting plants for general use, unless where franchises have been given the owners of the same shall have been remunerated as herein set forth.

2. That honorable manufacturers will not sell to municipalities until these steps have been taken, and central station men cannot afford to deal with manufacturers showing themselves thus dishonorable.

3. That if we cannot show to municipalities that the business is unprofitable to a city including, of course, the item of taxes, lost interest on investment, depreciation, etc., then we should be silent.

CONVENTION AND EXHIBIT NOTES.

AMONG THOSE PRESENT at the convention and not mentioned elsewhere were: F. A. Brown, M. A. Burt, G. L. Cole, E. Colman, F. A. Copeland, Edward Daniell, E. Debell, H. L. Doherty, C. Faust, T. F. Grover, G. W. Hanley, J. H. Harding, H. C. Higgins, F. Kellog, L. E. Kerns, P. H. Korst, R. F. Kountz, J. D. McLeod, G. S. McLaren, M. Nippert, C. C. Paige, H. F. Pearce, O. M. Rau, J. Schuette, W. C. Smith, G. H. Strang, R. A. Willson, H. F. Boggis, J. J. Brenk, W. L. Church, H. H. Pease, F. H. Ford, A. H. Ford, P. H. Karl, W. H. Scholt, W. Goltz, Thos. R. Mercein, Prof. D. C. Jackson, Albert Smith, H. Jones, G. L. Thayer, J. P. Barrett, S. G. Coleman, W. H. Schott.

THE GENERAL ELECTRIC COMPANY were represented by B. E. Sunny, Western Manager and George K. Wheeler, Chicago, C. D. Haskins, Boston, H. C. Wirt, Schenectady, N. Y., Percy A. Clisdell, Chicago, Thomas Ferris, Milwaukee. They exhibited a nice line of supplies in Parlor No. 8, near the Convention Hall. A line of samples of the new Wirt alternating current short gap lightning arresters, were displayed, together with their new 3 ampere and 5 ampere long burning arc lamps, type H. transformer and Thomson inclined coil instruments, which were all favorably commented upon. The Bulletin of the University of Wisconsin, containing a report of the complete test of Modern American Transformers, made by Mr. A. H. Ford, was distributed together with other literature. The apparatus manufactured by the General Electric Company for generating X-rays, as shown by Mr. Haskins, was the hit of the convention and elicited universal favorable comment.

THE COLUMBIA INCANDESCENT LAMP COMPANY, St. Louis, showed a fine display of their incandescent lamps, which included not alone their regular product, but they also had on view some 220 volt, anchored filament street railway type, and some of their fancy lamps. They also exhibited specimens of the material out of which the filaments are made, showing it in different stages of its manufacture; first the liquid mass which greatly resembles in appearance and consistency a thick varnish; the threads in the second stage; and also the coils of material ready for forming and carbonization, the carbonized filaments ready for treatment. This portion of the exhibit attracted considerable attention, and Mr. A. C. Garrison, secretary and treasurer of the company, who was in charge, explained the process of manufacturing the filaments to interested listeners.

THE AMERICAN ELECTRIC HEATING CORPORATION, of Boston, had a line of their electric heating apparatus, which included a set of cooking utensils, sad irons, and other specialties of the kind, the whole being in charge of Mr. F. P. Leuther, manager of the Western department, Chicago.

THE ELECTRIC APPLIANCE COMPANY, Chicago, were to the fore as usual and showed a fine line of supplies which, although they were not all exactly electrical, had quite an electrifying effect. The visitors to room 2 in the Pfister were cordially welcomed there by Mr. W. W. Low, the president of the company, and his able lieutenant, Frank McMaster.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, showed a new alternating current ceiling fan operated at 100 volts and 7,200 alternations, and it is so designed as to operate at the same speed as direct current ceiling fans. It has ball bearings, which rest in a cup filled with oil to last under ordinary conditions of operation 18 hours per day for two years without replenishing. There is but one bearing which consequently does away with a great amount of friction. The blades are attached direct to the revolving field and can be set at any angle desired. The switching device is located slightly above the motor proper, and is operated by a handle, which is the oil cup for the bearing already referred to. The motor is started by turning the oil cup to the right, and is stopped by turning the cup again in same direction, a continuous turning having the tendency to turn the motor on or off. It takes between 120 and 125 watts to operate it. It is absolutely impossible to burn this motor out, and the Wagner Company guarantee that it will operate with ordinary care and attention for a period of one year from date of purchase, and can be adapted to any height of ceiling. It is the intention of the Wagner Company to make only a limited number of these fans this year, and as things appear it would indicate they will not have to wait long before the anticipated lot is sold, judging from the attention it attracted and the many favorable comments passed upon it. It is rumored that the Wagner Company have already secured a number of orders for delivery this spring. They also exhibited a 20 light standard type transformer with their latest "X. L."

fuse boxes. Their carbon break, polished knife switches also attracted considerable attention, but what appeared to interest the visitors chiefly was a quick break baby switch. The spring comprising the feature of the quick break is located in the front of the post, and the mechanical construction of this switch is much more rigid than that of any of the baby switches that are now offered. The Wagner Company also distributed amongst the central station men several of their handsome transformer ink wells as souvenirs of their visit. The interests of the company were looked after in a very able manner by Mr. Eugene H. Abadie, manager of the Sales Department.

THE STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY, Chicago, were represented by Mr. M. C. Wheaton, and displayed a long distance telephone as well as central exchange desk outfits complete, and also magnetos, signal bells, and the intercommunicating system for interior use.

THE MUNICIPAL DEBATE. The leading feature of the convention centered on the subject of municipal ownership and the electrical men are thoroughly aroused on this matter. A strong effort was made to suppress the agitation, but it is evident that nothing but a final decision on this matter will satisfy the central station men of the Northwest. Many central station men expressed their regrets that Mr. Doherty, the former chairman, was not reappointed as he certainly worked hard and earnestly on this subject. The committee, however, is well manned for the coming year, and it is hoped they will accomplish much.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY showed a two-phase motor of 5 horsepower with a speed of 1,800 revolutions; also a Shallenberger integrating wattmeter for alternating currents, and some of their transformers. The alternating current which supplied the motor and also ran the rest of the exhibits at the convention, was supplied from the junction box patented by Mr. Jacob Cloos, of Milwaukee, who represented the Westinghouse Company at the convention.

MR. W. R. BRIXEY was present in the interests of Day's Kerite, and was welcomed by many friends. His able Western representative, Mr. S. F. B. Morse, was unfortunately prevented from putting in an appearance as he had hoped to do, but Messrs. Crook and Earl were around also attending to the interests of the company.

THE PECKHAM MOTOR TRUCK AND WHEEL COMPANY were represented by Mr. W. H. Gray of the Chicago office, who distributed a very handsome souvenir in the shape of a long memorandum book enclosed in a leather case, and for which there was considerable demand.

MESSRS. F. S. AND A. S. TERRY were present in the interests of the Sunbeam incandescent lamps, Cutter switches and circuit breakers and Lakon transformers.

THE NEW YORK INSULATED WIRE COMPANY were represented by their Western manager, Mr. James Wolff, and to say that he did things up in fine shape is only doing him small justice.

MR. GEORGE S. SEARING was present in the interests of the Hart & Hegeman Manufacturing Company, of which concern he is Western manager. Mr. Searing is a well known man at conventions.

THE WESTERN ELECTRIC COMPANY, Chicago, were represented by Mr. C. D. Wilkinson, who displayed his usual activity for the good of his company.

MR. M. B. AUSTIN was on the scene as representative of the Safety Insulated Wire and Cable Company.

THE C. E. GREGORY COMPANY, and The Electrical Exchange were represented by two hustling members of the firms in the persons of Mr. A. L. Kuehmstedt and Mr. T. S. Leane.

DONLEY & BUNCE, Chicago, as representatives of the Sawyer-Man Electric Company, and several other concerns, had a busy time of it, and Mr. W. E. Donley, and A. C. Bunce, the latter being a conspicuous figure at the Northwestern conventions since their beginning, were hard on the go during the entire proceedings.

THE CENTRAL ELECTRIC COMPANY, Chicago, were very ably represented by Messrs. C. G. Burton and W. P. Upham.

THE LESHEN-MACOMBER-WHYTE COMPANY, Chicago, had Mr. George Whyte on hand, and to state that Mr. Whyte is a pusher would be to express the case very mildly.

GOLTZ & SINCLAIR, Milwaukee, showed some Bergmann arc lamps in operation.

THE METROPOLITAN ELECTRIC COMPANY, Chicago, had Mr. Walter A. McKinlock on hand, who was very actively engaged in talking supplies, and on the merits of the Metropolitan oil filter.

MR. C. H. ROCKWELL, of the Buckeye Electric Company, Cleveland, O., was a visitor to the convention.

THE CHICAGO INSULATED WIRE COMPANY had their interests very ably looked after by Mr. W. M. Smith.

MR. CHARLES E. GREGORY, who was always a familiar figure at conventions up to a year or so ago, was on the ground again looking as fresh as ever.

THE PEOPLE'S ELECTRIC COMPANY, Madison, Wis., had Messrs. Burch and Ford around hustling after business for their concern.

J. C. WORMLEY & COMPANY were represented by Mr. J. C. Wormley, who was on the alert looking for lamp orders, and he added incidentally that his system of giving a discount off as he has advertised had borne good fruit.

A. O. SCHOONMAKER, New York, was represented by his Western sales agent, Mr. John Childs.

THE PRESS. The following representatives of the electrical press were present: L. L. Summers, "Electrical Engineering"; F. L. Perry, "Western Electrician"; W. P. Sullivan, The Electrical Engineer; J. V. S. Church, "The Electrical World"; W. R. Smith, "American Electrician."

THE FORT WAYNE ELECTRIC CORPORATION was represented by Mr. W. J. Buckley of their Chicago office.

MISCELLANEOUS. The following concerns also had representatives present: American Electric Heating Corporation, F. P. Luther, Chicago, manager; Diamond Electric Company, Peoria, Ill., W. Wilson; Chicago General Fixture Company; L. W. Kittwan; Ohio Brass Company, J. H. McGill, Western manager; A. L. Ide, A. L. Ide & Company; A. H. Pierce, Pierce & Richardson; Julian Roe, Sargent & Lundy; C. T. Gage, Washburn & Moen Manufacturing Company; D. G. McDonough, Washington Carbon Co.; W. D. Mahaney, M. A. Knapp; M. E. Baird, Eddy Electric Manufacturing Company; Jacob Cloos, Electrical Engineer, Milwaukee; Crouse-Tremaine Carbon Company; S. E. Christie, Dearborn Drug and Chemical Company; W. H. Grisson, Eureka Tempered Copper Works; A. Smith, Keelyn & Smith; J. Rohn, Rohn & Myer; F. J. Mocametz, Wisconsin Electrical and Construction Company.

NEW MEMBERS. Secretary Mercein furnishes the subjoined list of new members elected by the association: H. E. Shedd, Elgin, Ill.; J. Cloos, Milwaukee, Wis.; E. Reallic, Marquette, Mich.; W. Worth Bean, St. Joseph, Mich.; J. I. Case, Racine, Wis.; T. Ferris, Milwaukee, Wis.; W. H. Crawford, Milwaukee, Wis.; W. L. Church, Milwaukee, Wis.; M. E. Mayfield, Rockford, Ill.; E. Holcomb, Springfield, Ill.; W. L. Elliott, Chicago, Ill.; J. Bradshaw, Milwaukee, Wis.; Wagner Electric Manufacturing Company, St. Louis, Mo.; Columbia Incandescent Lamp Company, St. Louis, Mo.; G. L. Thayer, Belle Plaine, Ia.; A. S. Terry, Chicago, Ill.; W. P. Upham, Chicago, Ill.; Chapman Valve Manufacturing Company, Chicago, Ill.; Appleton Electric Light and Power Company, Appleton, Wis.; Westinghouse Electric and Manufacturing Company, Chicago, Ill.; F. B. Williams, South Milwaukee, Wis.; G. W. Harrison, Ashland, Wis.; J. R. Dee, Houghton, Mich.; A. H. McCorkle, Monmouth, Ill.; D. H. Pierce, Appleton, Wis.; C. E. Hay, Springfield, Ill.; C. T. Gage, Chicago, Ill.; Electrical Exchange, Chicago, Ill.; Kenosha Light and Power Company, Kenosha, Wis.; D. C. DeWolff, Chicago, Ill., and C. E. Gregory Company, Chicago, Ill.

THE ANNUAL BANQUET of the association was held on Wednesday evening in the banqueting hall of the Hotel Pfister, when some eighty people were present. At the conclusion of the banquet, and before the toasts were called, Mr. James Wolff arose as representative of the associate members, and made some very fitting and complimentary remarks in respect to the able and obliging manner in which Mr. Thomas R. Mercein, the secretary of the association, fulfilled the duties of the position. On concluding his speech Mr. Wolff presented Mr. Mercein with a very handsome gold badge, similar to the silver badge of the association, with the exception that the pendant from the gold circlet instead of being a tiny incandescent lamp, which is used, consisted of a large handsome solitaire diamond. Mr. Mercein responded in his usual inimitable manner, dilating at some length and with considerable feeling upon his appreciation of the compliment which had been paid to him. The following also spoke: J. C. Spencer, "The Great Northwest;" C. H. Hamilton, city attorney, "The Cream City;" George M. Hanley, "Marinette and Menominee;" L. L. Summers and F. L. Perry, "The Electrical Press." Prof. D. C. Jackson, B. E. Sunny, H. C. Higgins, W. J. Buckley. George Cutter, "Electrical Education." A band of music played during the evening. Mr. George Whyte favored the guests with a Scotch song, and Mr. F. McMaster went through his ludicrous "dwarf act" by walking around one of the tables on his haunches. The proceedings terminated at a late hour.

On Thursday evening the delegates attended at a vaudeville performance at the new Wihlein Theatre, which is one of the finest places of the kind in the West.

RULES AND REGULATIONS OF THE NATIONAL BOARD OF FIRE UNDERWRITERS.

Messrs. Pettingell, Andrews & Co., of Boston, have got up a neat pocket edition of these important rules, enclosed in Russia leather covers. The front cover bears the legend "The Golden Rule: Use Interior Conduit and Okonite Wire." A copy can be had on application.

HEATING AND VENTILATING.

The American Society of Heating and Ventilating Engineers will hold its third annual meeting this week at 12 West Thirty-first street, when a number of interesting and valuable papers will be presented in that field of work. The sessions begin at 10 a. m. Tuesday and last until Thursday afternoon.

NEW MEMBERS OF THE INSTITUTE.

At the meeting of the Executive Committee on January 20 the following associate members were elected: Putnam A. Bates, student, Columbia University, residence 113 West Seventy-second street, New York City; John Louis Hermessen, chief of Data Department, Union Electricitäts-Gesellschaft, Kleist Strasse, Berlin, Germany; Ludwig Hommel, Superintendent of Construction, Standard Underground Cable Company, Westinghouse Building, Pittsburg, Pa.; Wm. R. Kenan, jr., chemist and electrical engineer, Australian Carbide Company, Sydney, N. S. W.; Willard H. MacGregor, draughtsman, 359 West Twenty-seventh st., New York City; Calvin Winsor Rice, consulting electrical engineer, 8 Easton street, Winchester, Mass.; Francis Arthur Rich, Consulting Mining and Electrical Engineer, Auckland, New Zealand; D. Franklin Stakes, electrical expert, The Fort Wayne Electric Corporation, 240 West Washington street, Fort Wayne, Ind.; Samuel G. F. Townsend, electrical engineer, 131 Fifth avenue, New York City.

THE OHIO TELEPHONE ASSOCIATION.

The Ohio Telephone Association met at Columbus, Ohio, on January 11 and 12 and it was found that the organization, which has for its object the perfection of an inter-municipal telephone exchange, will equip it with long distance circuits. There are now in operation in Ohio and West Virginia sixty-three independent exchanges and almost 12,000 instruments in use. The following officers were elected for the ensuing year: James W. Thomas, Chillicothe, president; D. J. Cable, Lima, first vice-president; George W. Beers, Fort Wayne, second vice-president; J. W. Hoyle, Cambridge, third vice-president; H. J. Critchfield, Mt. Vernon, secretary, and Edward Kibbler, Newark, treasuer.

LETTERS TO THE EDITOR

ELECTRICITY vs. COMPRESSED AIR IN MINING PLANTS.

In the London "Electrical Review" of December 25, 1896, I note a letter by Mr. A. L. Steavenson in which he makes several attempts at criticising my article on "Electricity vs. Compressed Air" appearing in The Electrical Engineer of November 25, 1896.

My object in writing the article was to bring before those interested in the subject, actual working data of the two plants operating side by side under similar conditions, and I believe that this is the first real comparative test ever published. The article is simply a rehearsal of facts as I found them, and it cannot be said that I attempted to hide any defects of the air plant, for the fact they are very clearly indicated. It must also be considered that the electric plant was working under disadvantages due to underloading of both engine and pumps. I have noticed that the air men are very ready with figures on paper to attempt to show that compressed air transmission is more efficient than electricity, but I have yet to find a man who will show records of a compressed air pumping plant where the efficiency is any where near 50 per cent.

Now, regarding the particular criticisms. I have no doubt that our critic has written many interesting and instructive (?) articles of which the one about "headless ones in charge of mines" is probably the latest and the best, but not having read his best I fail to see the application. Our critic states: "The description of the pumps with their pipes is so obscure in its wording that I do not attempt to unravel it, but——" and then he describes the situation exactly! If this can be done without an "attempt to unravel it," the description must certainly have been very clear.

He goes on to say, "Of course, it was no part of Mr. Searing's business to ascertain why the air plant was giving less than 9 per cent., when, as Prof. Unwin has shown, that under intelligent care it might have afforded from 44 to 51 per cent." As there was nothing in the article to show whether the cause of the inefficiency of the air plant was investigated or not, he is not justified in his assumption that this was overlooked. As a matter of fact the plant was in good working order when tested, as it necessarily had to be to do the work required, and both the chief engineer and general master mechanic of the Fuel Company were there to take part in the tests and no doubt were interested sufficiently in having their own work fairly treated to know "how the tests were conducted" much better than any air man could from "a copy of the diagrams."

Although Prof. Unwin may have shown (on paper) that air transmission may have an efficiency of from 44 to 51 per cent., has he proved this to be the case under working conditions and with a mine pumping plant? Assuming the 44 per cent. could be obtained under exceptional conditions, how is the evil effect of operating this plant at an altitude of 6,000 feet above sea level to be counteracted, as it would have to be in the plant described. Our critic makes no mention of this point, and has perhaps never encountered a problem involving high altitudes. Take Prof. Unwin's plant to an altitude of 6,000 feet and his efficiency of 44 per cent. would drop to about 37 per cent. At 10,000 feet, an altitude very common in Colorado, his efficiency would drop to 32 per cent. Give Prof. Unwin the direct acting pump universally used in the United States instead of a complicated and delicate air engine to operate with his compressed air, and his efficiency would be nearer 9 than 37 per cent.

To our critic's question, "Why was the air not cooled by water injection during compression?" I would answer because it was cooled by a water jacket, as described. The expense of constructing these water jackets which our critic states as being "of no value at all" was undergone by the compressor manufacturers just for fun, and although I have seen the compressors run so smoking hot as to cause a shutdown wherever the water pipes to the jacket clogged up, yet the "headless ones in charge of the mine" would persist in the pernicious use of these same jackets. Our critic's method of ascertaining the leakage in the pipes is unique, "let the engine stand and ascertain how long it required for the pressure in the pipes to drop to zero." Determining the leakage to be so many minutes, hours or days would be of little value considering the pipes were conveying air, and not minutes or clocks.

The "slip-shod" calculations which he says contain an error of 22 per cent. are perhaps not so "slip-shod" as his assertion proves our critic's limited experience to be, for he has evidently used imperial gallons, whereas in the United States we naturally use United States gallons. If he will go over his figures using United States gallons, he will not only find no error in my figures, but a mistake in his computed error of 9.1 per cent.

LEWIS SEARING, Consulting Engineer,
The Denver Engineering Works Company.
Denver, Colo.

PERSONAL

MR. JAMES F. CUMMINGS, of the Armorite Interior Conduit Company, of Detroit, has been in New York for the past few days and has consummated a few important deals for the use of his conduit in the East.

MR. YSLAS, director of the Federal Telegraphs of Mexico, has issued to his friends a very handsome engraved card of New Year wishes, the background of which shows the network of main lines in red upon the map of Mexico.

MR. E. G. BERNARD contributes to "Cassier's Magazine" for February a very interesting article on "Electric Ship Lighting," of which he has long made a special study. He installed in 1884 the Sawyer-Man plant on board the U. S. man-of-war "Omaha," which was the second ship in our navy to receive the electric light.

MR. H. McNULTA, of Chicago, has become superintendent of the Helena, Mont., Power and Electric Company, taking the place left vacant by the resignation of Mr. A. B. Elliott.

MR. NICHOLAS S. HILL, JR., engineer to the Baltimore Subway Commission, whose excellent report was digested in The Electrical Engineer of January 13, has now been appointed chief engineer of the Water Department of that city. Mr. Hill is a highly accomplished and thoroughly trained engineer, and the selection of him for the post is admirable.

MR. E. WARD WILKINS, of the firm of Partrick & Carter Co., the well known manufacturers of Electrical House Goods and general supplies, has started on an extensive Western trip stopping at many of the principal cities between Chicago and San Francisco.

MR. MAX OSTERBERG, of The Electrical Engineer editorial staff, has succeeded in taking two splendid X-ray pictures of Yvette Guilbert's hands, and is the proud possessor of copies to which she has affixed a couple of charming autographic sentiments. The bones are curiously long, fine and delicate—artistic, even.

Mr. LOUIS H. ORR, one of the managing partners of the publishing and printing house of Bartlett & Co., so well known for its artistic work of the highest order, has just been elected a governor of the New York Athletic Club, without opposition. Mr. Orr has a host of friends in electrical circles, is an accomplished athlete and bicyclist, and is popular everywhere.

PROF. A. M. BELL has changed his allegiance at last, according to the "Washington Times," and on January 12 became a citizen of the United States. He is the father of Prof. A. G. Bell, and was born in 1813.

PATTON-THRALL.—Invitations are out for the marriage of Mr. Edward Kendrick Patton, on Tuesday, February 9, to Miss Jeanne Thrall, of Cincinnati. Mr. Patton has been associated with the electrical business for years, more especially in late years with the incandescent lamp industry. At present Mr. Patton is manager of the Chicago office of the Perkins Electric Switch and Manufacturing Company, and is deservedly popular amongst the general trade.

MARRIED

HOWARD-PAYSON.

Charles T. Howard, secretary and treasurer of the Providence Telephone Co., and Miss Gertrude Payson, both of Harris, were married at the home of the bride's mother at Harris on January 5. The wedding was a quiet one, only the immediate members of the two families witnessing the ceremony, which was performed by Rev. C. H. Smith, pastor of the Phenix Methodist Episcopal Church.

BURKE-RYDER.

The marriage occurred on Jan. 14, at Salem, Mass., of Mr. Frederic Sherman Burke and Miss Bessie Ryder, daughter of Mr. J. Orme Ryder, secretary and treasurer of the Crown Woven Wire Brush Company, of which Mr. Burke is the manager. The ceremony was celebrated in St. Peter's Church and was largely attended by friends from Boston, Providence and New York. The happy pair received gifts both numerous and costly, and left for a prolonged wedding tour.

LEGAL NOTES

DAMAGES WANTED FOR TEARING DOWN NEW YORK WIRES.

The trial of a suit brought to recover $250,000 from New York City by the Electric Power Company for the summary removal of the poles and wires belonging to the company, pursuant to an order made in 1889 by the Mayor, was begun before Justice McLaughlin in the Supreme Court recently.

Roger Foster, counsel for the plaintiff, said the Mayor's order was the result of an attack upon the system of overhead wires in the city, but that the right possessed by the Electric Power Company to hang overhead wires could not be taken away without compensation. Not only, said counsel, did the city remove the plaintiff's wires, but sold about $10,000 worth of them and refused to give up the money. The company had, he said, invested $300,000 in the business, and would have made money but for the action of the city.

Assistant Corporation Counsel Connoly maintained that the orders of the Mayor were an act of the Legislature for the removal of overhead wires, and that they had not been taken down until subways were ready for them.

OBITUARY

LOUIS HART.

As we go to press, we regret to receive the news of the death from blood poisoning, consequent upon a former attack of grip, of Mr. Louis Hart, so well known in connection with "Heating and Ventilation," an excellent paper, founded by himself a few years ago with much success. Mr. Hart was an old railroad man; was at one time in the electrical field, and at the time of his death was secretary of the Society of Heating and Ventilating Engineers. He was a popular man everywhere and was still in the prime of life. He leaves a widow and one son. As he was a prominent Odd Fellow, his funeral is in charge of that organization.

EDUCATIONAL

UNIVERSITY OF NEBRASKA.

Prof. R. B. Owens, head of the electrical engineering department of the University of Nebraska, informs us that on January 8, under highly auspicious conditions, the Nebraska Engineering Society was organized at Lincoln, where its permanent home will be. The meetings will be held from time to time in different parts of the State. Professor Owens is on the Executive Committee.

Mr. B. J. Arnold, the well-known electrical engineer of Chicago, is to visit the University in February, to give a course of ten lectures on central station design and construction.

THE NOBEL SCIENTIFIC PRIZES.

ALFRED NOBEL, the engineer and inventor of dynamite, has left his fortune for the advancement of science throughout the world, to be administered by learned bodies at Stockholm. The will was drawn up at Paris on November 27, 1895, and was opened at Stockholm on December 30 last. After disposing of two or three million francs in bequests to about twenty persons, friends, relatives and servants, it goes on to say, according to "Le Figaro":

All the residue of my fortune that can be realized shall be disposed of as follows: The capital converted into safe securities by the liquidators shall constitute a fund, the income of which shall be distributed yearly to those who during the year preceding shall have rendered the most eminent services to humanity.

The income shall be divided into five equal parts, which will be awarded yearly:

The first to the person who shall have made the most important discovery or invention in the domain of physics.

The second to the person who shall have made the most important discovery or improvement in the domain of chemistry.

The third to the person who shall have made the most important discovery in the domain of physiology or of medicine.

The fourth to the person who shall have produced the greatest work in the ideal sense in the domain of letters.

The fifth to the person who shall have exerted the greatest or the best action for the fraternity of peoples, for the suppression or diminution of permanent armies and for the formation or spreading of Peace Congresses.

The first two prizes (Physics and Chemistry) shall be awarded by the Academy of Sciences of Sweden; that for physiological or medical works by the Carolus Institute of Stockholm; the literary prize by the Swedish Academy, and that for the spreading of peace by a committee of five members chosen by the Norwegian Storthing.

It is my express will that no consideration of nationality should be taken into account in awarding these prizes, so that the most worthy may receive the reward whether he be a Scandinavian or no.

Mr. Nobel's convertible fortune consists of real property in Paris and San Remo, but for the greater part of securities deposited in his house at Paris, and with bankers in London, Paris, Berlin, St. Petersburg and Stockholm. It will take some time to find out the exact amount of the bequests, but it is safe to say that it will amount to at least $10,000,000, and that each of the yearly prizes established by Mr. Nobel will be as large as $60,000. These are tne largest prizes that have ever been established. It remains to be seen what advancement of the objects which M. Nobel had at heart will be attained by so profuse liberality.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JANUARY 12, 1897.

Alarms and Signals:—

ELECTRICAL SIGNAL SYSTEM. R. Skeen, Madison, Ill., 574,953. Filed March 4, 1895.

Adapted for grade crossings on electric railways.

ELECTRIC SIGNAL. R. Skeen, Madison, Ill., 574,954. Filed May 11, 1895.

Self-locking means automatically operated by electrical connections whereby the signal will be locked, and also the switch mechanism controlling the signal.

RAILWAY SIGNALING SYSTEM. N. Henquin, Schenectady, N. Y., 575,065. Filed October 8, 1896.

Apparatus operated by the engine of a train at a starting station to signal and record on paper the time of departure and rate of speed of the train at stations along the route.

ELECTRIC BELL. J. W. Holdsworth, St. Louis, Mo., 575,156. Filed April 9, 1896.

A stationary electro-magnet is combined with a coil wound upon a vibrating armature.

Conductors, Conduits and Insulators:—

CLEAT. C. F. Adams, Trenton, N. J., 575,090. Filed May 11, 1896.

Embodies a groove for the reception of the wire, the groove being provided with teats placed at an angle to the direction of the groove and to the wire.

ELECTRIC CONDUCTOR. H. T. Richards, Brooklyn, N. Y., 575,170. Filed Nov. 20, 1896.

A conductor provided with a braided covering, one of the threads of the braiding being thicker than the other to serve as a distinguishing mark when used with other conductors.

Dynamos and Motors:—

MEANS FOR ADJUSTING COMPOUND WOUND DYNAMOS. B. G. Lamme, Pittsburg, Pa., 574,914. Filed Dec. 28, 1893.

Consists in varying its compound effect, while maintaining a constant resistance between its terminals.

DIRECT CURRENT DYNAMO ELECTRIC MACHINE. M. Hutin and M. Leblanc, Paris, France, 575,115. Filed Feb. 12, 1894.

Of the closed circuit armature type, provided with a commutator having a lesser number of segments than there are armature sections, and means for rotating the commutator at a proportionally higher speed than the rotor.

DYNAMO ELECTRIC MACHINE. G. L. Campbell, Kinsman, O., 575,210. Filed Oct. 8, 1895.

Comprises supports movable toward and from the armature, field magnets pivotally carried by the supports, and means for holding the field magnets in position.

STATIC GENERATOR. A. J. Gawne, Sandusky, O., 575,231. Filed Oct. 10, 1896.

Of the "Wimshurst" type.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. R. O. Hood, Danvers, Mass., 574,905. Filed July 6, 1896.

Comprises a mass whose expansion under the action of the electric current separates the carbons employed therein and a magnet in series with the arc for feeding the carbons toward each other when the current flowing across the arc is at a predetermined value.

GAS FIXTURE. E. A. C. Kaysel, New York, 574,907. Filed June 24, 1896.

The electric conductors are carried in the same pipe with the gas.

ILLUMINANT FOR INCANDESCENT LAMPS. A. De Lodyguine, Pittsburg, Pa., 574,002. Filed Jan. 4, 1893.

A filament composed of an incandescent metallic body and containing a conducting fillet of different material.

ELECTRIC CURRENT REGULATOR. W. Hawker, Windsor Mills, Canada, 575,235. Filed Sept. 25, 1896.

Adapted for use with incandescent lamps.

Miscellaneous:—

ELECTRIC CIGAR LIGHTER. J. W. Dawson, Louisville, Ky., 574,889. Filed Aug. 17, 1895.

Combines a cigar cutter, lighter and advertising device.

ELECTRIC CALENDAR CLOCK. G. W. MacKenzie, Beaver, Pa., 574,922. Filed Dec. 28, 1895.

Secondary clock, details of construction.

ELECTRIC VALVE APPARATUS. J. V. Stout, Easton, Pa., 575,045. Filed June 7, 1892.

Intended for steam valves.

BICYCLE ELECTRIC BELL. H. B. Ewbank, Jr., Baltimore, Md., 575,059. Filed May 18, 1896.

Means whereby all the parts may be mounted on the handle bar so that all shall remain immovable to each other.

ELECTRICALLY OPERATED PIANO ATTACHMENT. E. G. Simpkins, Toledo, O., 575,072. Filed Dec. 26, 1895.

An attachment whereby any particular key may be operated to give a predetermined tone, and at the same time the hammer mechanism may be controlled to give the desired volume of tone.

AUTOMATIC ELECTRIC MARINE SOUNDING APPARATUS. J. F. Babcock, Bangor, Me., 575,093. Filed March 11, 1896.

Details of construction.

MANUFACTURE OF CASTINGS. A. E. Hunt, Pittsburg, Pa., 575,115. Filed Sept. 21, 1896.

Consists in heating the metal by first passing a current of electricity through the conductive material of the mold and substantially through the entire length of the mold, and then progressively shortening the portion included in the electrical circuit.

APPARATUS FOR STOPPING ENGINES. G. W. Brown, West Newbury, Mass., 575,144. Filed Oct. 4, 1895.

Comprises a vent controlling valve, an actuator therefor, an armature serving as a detent normally restraining the actuator, and speed controlling means actuated by the power of the engine to displace the detent by the centrifugal force.

Measurement:

ELECTRIC METER. J. Hessberger, Niedersedlitz, Germany, 574,903. Filed Aug. 10, 1895.

Comprises means for producing a magnetic field, a bismuth conductor movable in the field and indicator connected with the bismuth conductor.

Railways and Appliances:—

ELECTRIC RAILWAY. L. Dion, Natick, Mass., 575,053. Filed Dec. 30, 1895.

Closed conduit system.

ELECTRICAL PROPULSION FOR RAILWAY CARS. L. Dion, Natick, Mass., 575,054. Filed Feb. 27, 1896.

Embodies a main electrical conductor having its upper surface grooved longitudinally, and a flexible, helically formed auxiliary electrical conductor adapted to normally rest in the groove of the main conductor.

TROLLEY HEAD FOR ELECTRIC CARS. W. S. Troutwine, Indianapolis, Ind., 575,080. Filed May 22, 1896.

A trolley head in which the wheel can be removed and a scraper inserted in its place, and to provide a scraper that can be quickly applied and that will be effective in removing ice and sleet from the wires.

TROLLEY STAND. J. E. Bishop, Indianapolis, Ind., 575,099. Filed Aug. 22, 1896.

Details of construction.

ELECTRIC RAILWAY. G. W. C. Lomb, Birmingham, Ala., 575,303. Filed Feb. 18, 1895.

The conductor is enclosed in an isulating tube and contact is had with the trolleys through contact-pieces embedded in the tube by the collapsing of the tube upon the passage of the trolley wheel.

ELECTRIC LOCOMOTIVE. William L. Silvey, Dayton, O., 575,314. Filed Nov. 7, 1895.

Details of construction.

Switches, Cut-Outs, Etc.:—

COMBINED RHEOSTAT AND REVERSING SWITCH. J. P. B. Fiske and C. P. Smith, Alliance, O., 574,896. Filed March 18, 1895.

Designed for controlling motors for propelling vehicles.

CONTROLLER FOR ELECTRIC MOTORS. H. P. Davis, Pittsburg, Pa. 574,885. Filed Dec. 3, 1895.

Controller of the commutator type especially applicable in crane and elevator work.

OVERHEAD ELECTRICAL KNIFE SWITCH. J. Menchen, Kansas City, Mo., 574,926. Filed Feb. 25, 1896.

A knife switch provided with pivotal terminals and retractile springs connected with each pair of pivotal terminals.

ELECTRIC QUICK BREAK SWITCH. A. H. Armen, Philadelphia, Pa., 575,047. Filed March 30, 1896.

Comprises a switch lever and push button working in planes perpendicular to each other, with a button arm auxiliary to the button and a spring working between the switch lever and button arm.

SYSTEM OF LIGHTNING PROTECTION FOR ELECTRIC CIRCUITS. A. Wurts, Pittsburg, Pa., 574,987. Filed July 19, 1893.

Combines a source of current, translating devices, and a line circuit provided at suitable intervals with underground inductive resistances, the resistances serving to dissipate static charges by transforming their energy into heat.

DEVICE FOR PROTECTING ELECTRIC CIRCUITS. A. J. Wurts, Pittsburg, Pa., 574,979. Filed Oct. 2, 1895.

The combination with a lightning arrester of a choke coil provided with a slotted strip of insulating material in contact with several of the turns thereof, a conducting strip of the insulating strip and an insulating covering for the parts.

Telegraphs:—

PRINTING TELEGRAPH. B. Hoffmann, Paris, France, 574,994. Filed July 17, 1895.

Comprises a transmitting keyboard, a receiving mechanism, a call bell, and a series of switches for effecting different circuit connections, the two stations being connected by a single line wire.

REPEATER. W. M. Chapman, Needham, Mass., 575,025. Filed Dec. 12, 1895.

"Non-interfering" repeater.

Telephones:—

TELEPHONE. C. C. Gould, Philadelphia, Pa., 574,901. Filed April 29, 1895.

Comprises a diaphragm, rolling electrode and a plate provided with outwardly projecting pointed arms having beveled edges for the accommodation of the rolling electrode.

SIGNALING APPLIANCE FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 575,131. Filed Nov. 4, 1895.

Comprises a plug circuit, a calling key in the plug circuit and a generator of signaling current having the terminals of its armature connected with switch contacts of the calling key, and a ground connection to the middle point of the active wire of the armature.

TELEPHONE SYSTEM. J. H. Weckel, Breakabeen, N. Y., 575,186. Filed March 7, 1896.

Means for connecting any one of a series of branch lines in circuit with stations on the main line either above or below the points of exchange.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JANUARY 19, 1897.

Alarms and Signals:—

RAILROAD SIGNAL. W. F. French, Omaha, Neb., 575,601. Filed April 23, 1896.

A railway track signal adapted to be sounded by the wheels of a train moving in one direction only, being idle when encountered by a train moving in the opposite direction.

PUSH BUTTON. C. O. Mailloux, New York, 575,528. Filed June 4, 1896.

Comprises the contact mechanism in a push button, a case enclosing the same, the circuit terminals of the mechanism located exteriorly to the case, and a removable face plate covering the terminals.

Batteries, Primary:—

TELEGRAPH BATTERY JAR. A. L. Werner, Delano, Pa., 575,449. Filed June 29, 1896.

Provided with an integral spout and having its rim formed into outwardly projecting hand grasp flanges which extend almost around the jar.

Connectors, Conduits and Insulators:—

WIRE COUPLING. W. Gerard and J. H. Lawrence, Bond Hill, Ohio, 575,641. Filed November 23, 1896.

Consists of a sleeve having a bore at each end, two serrated jaws in each bore adapted to engage the end of a wire.

Lamps and Appurtenances:—

INCANDESCENT LAMP SOCKET. R. B. Benjamin, Chicago, Ill., 575,322. Filed March 16, 1896.

Means for mounting the socket upon the conduit carrying the conductors.

CLUTCH FOR ARC LAMPS. E. Finkbeiner, Brooklyn, N. Y., 575,341. Filed July 27, 1896.

Details of construction.

ILLUMINANT FOR INCANDESCENT LAMPS. A. De Lodyguine, Pittsburg, Pa., 575,668. Filed April 10, 1894.

Consists in imparting the desired shape to a conducting fillet, immersing the fillet in a mixture of hydrogen and a gaseous chlorin compound of a refractory metal, and heating the fillet while so immersed.

Miscellaneous:—

ELECTRICALLY ILLUMINATED JUGGLERY APPARATUS. M. Cronin, London, England, 575,332. Filed October 30, 1896.

Consists in jugglery apparatus containing electric glow lamps and battery in the interior of a partly transparent outer frame.

DEEP-SEA ELECTRIC CURRENT METER. C. L. Berger, Boston, Mass., 575,455. Filed September 28, 1896.

Comprises a rotator, its shaft bearings therefor and electrical make-and-break devices, combined with an oil-well for the latter, the make-and-break devices being mounted in the upper portion of the oil-well and the latter having an extended lower portion open freely below the make-and-break devices.

FLOATING TRACTION DEVICE. T. P. Milligan, Cambridge, Md., 575,488. Filed March 26, 1896.

A rail adjacent to the surface of the water, a boat carrying a suitable motor, a traction device connected with the motor and provided with rolls arranged to grip the rail, and a suitable connection for towing the load.

APPARATUS FOR PURIFYING OR DISINFECTING. E. Hermite, Paris, France, 575,645. Filed January 17, 1894.

Consists of electrolyzing a solution containing chloride of magnesium and subjecting the material to be disinfected to the action of the electrolyzed solution.

ELECTRICAL CONDENSER. J. C. Lee, Brookline, W. R. Westcott, Cambridge and E. C. Robes, Medford, Mass., 575,653. Filed July 8, 1896.

Consists in winding strips of the material constituting the plates and of the dielectric, in layers onto a flattened roll, and in subjecting it to pressure whereby the material of the dielectric is caused to yield, and the strips constituting the plates and dielectric are brought into intimate contact and caused to cohere, thereby forming the roll into a thin, flat rectangular solid having rounded ends.

GALVANIC ATTACHMENT FOR EYEGLASSES. A. Mayer, New York, 575,658. Filed June 3, 1896.

Comprise contact batteries to produce a therapeutic current.

MAGNETIZING BOX. C. A. Hussey, New York, 575,679. Filed August 10, 1895.

A containing case having a metallic bottom and magnetized upturned ends.

Railways and Appliances:—

ELECTRIC RAILWAY. W. Grunow, Jr., Bridgeport, Conn., 575,346. Filed October 28, 1895.

An underground conduit for a conductor which employs a depressible rail on which the trolley bears so as to be brought into contact with the conductor.

ELECTRIC RAILROAD. W. Jens, Johnstown, Pa., 575,354. Filed June 30, 1896.

A portion of metal similar in nature to the metal of the bond-bar, integrally united to the rail and adapted to have the bond bar attached to it.

RAIL BOND AND CONNECTION. M. K. Bowen, Chicago, Ill., 575,388. Filed October 9, 1895.

A bond of relatively small cross section having enlarged ends in contact with the rail.

SERIES MULTIPLE CONTROLLER FOR ELECTRIC MOTORS. E. M. Bentley, Lawrence, N. Y., 575,454. Filed November 13, 1896.

Comprises a shunt for the two motors containing a resistance, an automatic circuit breaker placed in the series circuit between the two inner terminals of the shunts and dependent on the volume of current passing therein.

ELECTRIC MOTOR AND DEVICE FOR CONDUCTING CURRENTS THERETO. D. N. Osyor, Columbus, Ohio, 575,615. Filed October 17, 1889.

Adapted for use in motor cars in mine railways.

Regulation:—

ELECTRICAL CONTROLLER. W. H. Morgan, Alliance, Ohio, 575,366. Filed September 4, 1895.

Comprises an open main frame, an annular open frame within the main frame, and an annular series of resistance coils spaced apart and supported on the annular open frame.

ELECTRIC ELEVATOR OR HOISTING MACHINE. R. M. Hunter, Philadelphia, Pa., 575,479. Filed April 5, 1894.

MEANS FOR OPERATING ELECTRIC MOTORS. J. F. McLaughlin, Philadelphia, Pa., 575,490. Filed September 1, 1891.

Comprises a clutch for coupling the motor to the work, a brake for the motor armature, and connections between the clutch and armature brake for operating them in succession.

ELECTRICAL CONTROLLING APPARATUS. O. H. & A. F. Pieper, San Jose, Cal., 575,573. Filed December 19, 1895.

Adapted for controlling motors operating dental apparatus.

Telegraphs:

TELEGRAPHY. P. B. Delany, South Orange, N. J., 575,419. Filed April 21, 1896.

Feed mechanism for tapes in printing telegraphs.

Telephones:—

MAGNETO TELEPHONE. S. D. Field, Stockbridge, Mass., 575,394. Filed August 11, 1896.

Adapted to be used as a receiver.

COUNTER E. M. F. REGULATION OF ELEVATOR MOTORS.

A patent has just been issued to Mr. R. M. Hunter, No. 575,479, January 19, 1897. This patent, it is claimed, covers the method of controlling elevator motors by means of a counter e. m. f. device.

REPORTS OF COMPANIES

A WINTER CHILL.

It is well, on the whole, that a recovery should not go too fast, and for such a reason the slight irregularity and reaction in Wall street last week may be regarded with equanimity. Disquieting rumors were afloat as to some of the railroads, but nothing happened to justify them, and the undertone of the market in general was strong, the ease in money being reflected by the low rate for loans and the activity in the bond market. In industrial circles quietude and a waiting policy prevailed, though nobody seems to know why. Bradstreet's says that while trade is proceeding on conservative lines the volume is slowly increasing.

In New York, electrical stocks show a slight decline, General Electric having opened the week at 35½ and falling to 34⅛, on sales of 18,326 shares; while Western Union on sales of only 6,967 shares ranged during the week between 86 and 83⅞. In Boston, American Bell, however, showed a decided gain from 209½ to 213, but only 842 shares were sold, or less than 150 per day.

The New York Edison Co.'s annual report makes a most excellent showing, and is evidence of the general betterment of local companies. Its gross earnings for the year were $2,247,437, its net $1,080,156, and its gain in balance after providing for bonds, 6 per cent. dividends and depreciation, no less than $158,976. The gain in gross business over 1895 was $246,581, and in net $102,105.

REORGANIZATION OF THE ST. LOUIS EDISON CO.

The Edison Electric Company, St. Louis, which has long been burdened by the interest charges it had to pay on its $4,000,000 bonded indebtedness, is said to be seeking relief in the shape of a reorganization, of which the scheme is that the interest-bearing coupon, due February 1, is not to be paid. Each holder of a $1,000 6 per cent. bond is to be offered a new $500 4 per cent. bond, and 10 shares of preferred and 10 shares of common stock in the reorganized concern. This would reduce the bonded indebtedness by $2,000,000 and the annual interest charge from $240,000 to $100,000.

T. J. MURPHY & CO.—Schedules of T. J. Murphy & Co., manufacturers of electrical supplies at 511 West Thirteenth street, New York, show liabilities of $6,806, nominal assets of $10,293, and actual assets of $8,347.

W. C. WHITNEY'S COMPRESSED AIR COMPANY.

A certificate has been filed with the County Clerk by the Compressed Air Power Company, showing that one-half of its stock of $1,000,000 has been paid in. The directors of the company are: William C. Whitney, Thomas J. Ryan, Frederick S. Pearson, William W. Cook, and William L. Elkins.

ENCLOSING THREE DOLLARS.—A St. Louis reader is kind enough to write: "I have been buying your good-for-nothing, no account sheet from news dealers for over four years, and I intend to stop doing so. My reason is that I have become convinced I cannot get along without it, as I consider it the best paper for a street railway man. I herewith enclose $3 for one year's subscription. I can testify that the Engineer has been worth more to me than the $5.20 per year that I have been paying for it."

TRADE NOTES & NOVELTIES

ISOLATED LIGHTING PLANTS OF C. & C. 4-POLE COMBINATIONS.

THE combination of C & C dynamos and engine, illustrated in the accompanying engraving, is specially designed for small isolated lighting plants, such as steamer and house lighting, and wherever space and weight are important factors. Standard flange couplings connect the dynamo to the engine, the entire combination being securely bolted to a sub-base. Perfect alignment is thus insured, while at the same time this arrangement facilitates the repairing of both the engine and dynamo; in fact, they are absolutely independent of each other.

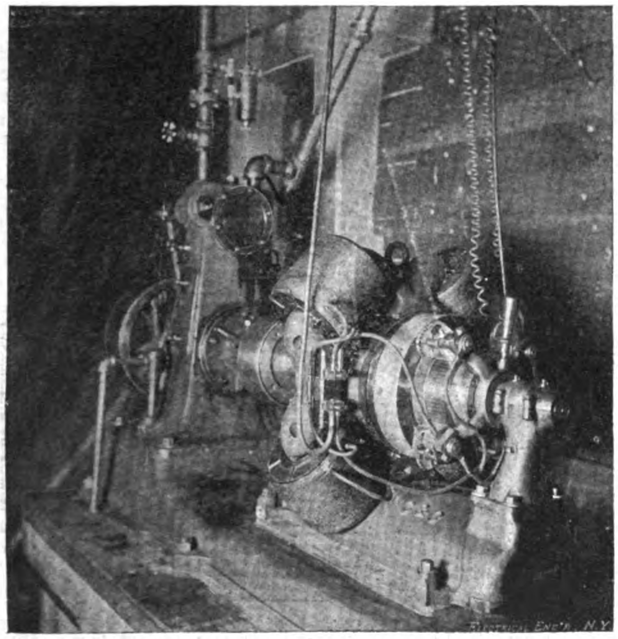
The speeds of these combinations, which are built in various sizes, are based on 80 pounds pressure one-quarter cut-off, and, with the compound-wound dynamo, permit of excellent regulation, producing a steady light, unaffected by load changes.

The temperature increase is less than 40 deg. Centigrade under full load in continuous service.

The material and workmanship are first-class, and the combination is of handsome appearance, as shown in the accompanying engraving.

The C & C Co. also build a 4-pole motor of a type similar to the generator illustrated.

The armatures are of the ring type, designed to secure good ventilation and low heating effect. The windings are ample, and the commutators especially have large surface area and brush contact. The insulation throughout is of the best, insuring long life.



C & C 4-POLE COMBINATION.

The mechanical construction is very rugged and the bearings are self-oiling, making these machines well adapted for hard usage.

The C & C Co. recommend this type of motor as being economical, smooth running, of high efficiency and of large starting torque, making it specially adapted for direct connected elevator work or printing press driving, and whenever countershafting is objectionable.

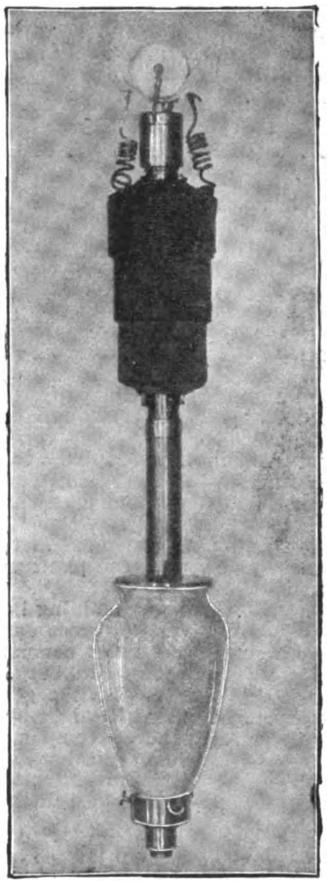
MR. F. S. PALMER, general manager of the Electric Heat Alarm Company, 145 High street, Boston, reports closing a very nice contract for an equipment in a coal pocket belonging to the City and Suburban Railway Company, Baltimore, to be installed under the supervision of the electrical engineer, Mr. P. O. Keilholtz. The outlook for this thermostatic appliance is excellent.

THE UPTON LONG-BURNING ARC LAMP.

AS is frequently the case when a departure from the customary types of an apparatus is brought out, the desire to be early in the field leads to the placing on the market of devices which are not always reduced to the simplest elements.

Believing that the simplest lamp with the fewest parts to wear or mechanism to get out of order, one that would combine steadiness and economy of light with a minimum of attention from the user in order to operate successfully, would most surely and satisfactorily meet the requirements of the case, the makers of the Upton Long Burning Lamp have kept these points most prominently in mind. Now that their lamp is perfected and on the market, they with good reason claim that the result has justified the wisdom of their course, in postponing its appearance until perfection had been attained.

The description of the Upton Long Burning Lamp below shows that it is an entirely new departure in arc lamp manufacture. There is absolutely no mechanism in its make-up, such as gears, clutches, chains or ribbons; in fact, all appliances which will wear, gum or stick and require cleaning or adjustment are entirely dispensed with in this lamp. All that is used is electricity and gravity. The current flowing through the solenoid magnetizes the armature, to which is attached the carbon, draws and holds the arc, and as the carbon is consumed the force of gravity maintains a positively steady and constant feed.



THE UPTON LONG-BURNING ARC LAMP.

The frame of the lamp is a brass pipe, threaded at both ends, over which is fitted the solenoid or magnet. This magnet is perfectly ventilated and machine wound, each layer of wire being coated with an insulating paint as the winding progresses, and the whole when completed baked to withstand a temperature of 400 degrees Fahrenheit; then it is tested at 1,000 volts pressure for leaks and short circuits, thus insuring a coil that will not burn out from any heat generated in the lamp.

The armature which is the only moving part of the lamp, is an iron pipe, which acts as carbon rod, holding the carbon at its lower end. A cast flange threaded on the outside is screwed to the bottom of frame and fits into a threaded ring attached to the inner globe, by which it is supported and completes the sealing of globe, thus forming an airtight joint at the top.

The lower carbon holder is fitted to the inner globe, by which it is supported and completes the sealing of the lamp.

In the lamp for outdoor service, the resistance and switch are fitted inside the hood. For indoor use the resistance is fitted on the cover at the top of the outer globe, provided in both cases with a changeable cut-out enabling the lamp to burn on any voltage desired from 85 to 125 volts.

The makers can furnish the lamp to consume from 3¾ to 5 amperes, as desired.

After the lamp is once in position, the labor of trimming is reduced to a minimum. When the outer globe is lowered, one turn of the ring of the inner globe holder and the same is unfastened; another turn of a thumb screw and the lower carbon is ready to be removed. The unused portion of the positive carbon is then placed in the lower carbon holder and a new 12-inch carbon placed in the upper holder, the latter forced up as far as it will go, the inner globe and lower holder replaced with a turn of the ring and screw, and the lamp is ready for current again.

The lamp is absolutely steady in operation, gives a white light without any shadow, as there is no lower frame extending into the globe to cause this objectionable feature; burns on the amperage for which the magnet is wound from the moment the current is turned in and does not vary.

The Standard Thermometer and Electric Company, of Peabody, Mass., who manufacture the Upton lamp, invite correspondence and will cheerfully give any further information that may be desired.

LARGE ORDERS FOR THE BALL ENGINE.

The vertical engines built by the Ball Engine Company, of Erie, Pa., for electric service have been received with favor by those who appreciate merit and good workmanship in an engine. Since October 1 last, these works have been running till 10 o'clock every night, and part of the time all night, on account of several large contracts received for vertical engines. Some of these orders are just being completed. Among these is a 400 horse-power vertical cross compound engine, arranged for direct connection to a 225 kilowatt Siemens-Halske generator, whcih was shipped a few days ago to the Nicopol Mariopol Mining and Metallurgical Company, Mariopol, Russia, and will furnish electric power to various machinery in the steel works mentioned.

The company will ship in a few days to the Chicago Public Library four 200 horse-power vertical cross compound and one 100 horse-power vertical tandem compound engine, each engine being direct connected to two General Electric Company machines. The form of arrangement and the details of these engines are entirely new, and the plant when erected will be a very complete one.

Besides the above, there are building in the works at present one 400 horse-power vertical cross compound engine, and one 150 horse-power vertical cross compound engine, for the Shoenberger Steel Company, of Pittsburg, Pa., each of which is direct connected to Siemens-Halske generators.

Also for the Apollo Iron and Steel Company, of Apollo, Pa., one 150 horse-power vertical cross compound engine direct connected to a General Electric alternating lighting machine, both the dynamo and exciter being driven from the shaft of the engine, and arranged on the same base with the engine.

PROMPT WORK BY THE WAGNER CO.

Mr. E. H. Abadie, manager of the sales department of the Wagner Electric Manufacturing Company, St. Louis, sends us the following note, which indicates laudable swiftness in executing a hurried request for apparatus:

An order was recently secured by us aggregating over 7,000 lights capacity in standard transformers; the requirements of the sale were immediate delivery. We received the order over the Long Distance Telephone located in our office at five o'clock on the evening of January the 13th. For transporting this order one of the largest cars was required, with an ability to carry thirty odd thousand pounds. By ten o'clock on the 14th of January the car was loaded, it left that evening at four o'clock for Chicago and was delivered the following morning at seven o'clock. The following is a copy of part of a letter from the purchaser, and you will note his appreciation of our prompt attention to his order: "You are certainly to be congratulated upon the promptness in filling and shipping the order and it occurs to us that the ability of a manufacturing company to so promptly respond to urgent requests for so large transformer capacity is a good argument for the use of their make of transformers. We do not understand that any other one manufacturer was prepared to accept the order and guarantee delivery within the time required." Our ability to make prompt shipment has resulted in a great deal of business.

THE QUEBEC ELECTRIC RAILWAY.

The contract for the complete rolling stock of the Quebec Electric Railway, including cars, motors, etc., has been awarded to Ahearn & Soper, of Ottawa. The system at Quebec will be as nearly as possible a duplicate of that at Ottawa which is recognized as a model. The motors used will be of Westinghouse make, and will be specially adapted for the grades which exist at Quebec.

DIRECT-CONNECTED PRINTING PRESSES IN MILWAUKEE, WIS.

PROBABLY one of the most completely arranged printing establishments in the West is that of the Germania Printing Company, Milwaukee, Wis. Their new home consists of a massive eight-story stone and brick structure of Italian renaissance style. It is the home of one of the largest and wealthiest publishing houses in the West. The president is Mr. George Brunder, one of Milwaukee's solid old pioneers, who has accumulated a large fortune by his industry and honesty. His name is familiarly known throughout the West among leaders of Western journalism. Electric drive has been adopted for all the machines, presses and elevators in this building. The contract for the equipment of these presses and machines with motors has been awarded to the Northern Electrical Manufacturing Company, of Madison, Wis., for direct connection of a "Northern" spherical steel invertible motor to each separately. It has been the desire of the engineer in charge of this building (A. M. Patitz, of Milwaukee), to make it the most complete electrically of any printing establishment in the West. Simplicity and substantiality in design, economy in operation and high efficiency of all machines are the salient features. The basement and two top floors are for the presses, typesetting and bookbinding machines, direct connected to "Northern" electric motors. The intermediate floors are offices, single and en suite, to meet any requirement and furnished with every modern convenience. We understand there were a large number of bids presented for the large electrical equipment of this building, and the Northern Electrical Manufacturing Company were certainly very fortunate in securing the work. This company started in a small way about two years ago, but, unlike most small concerns, they are fortunate in the possession of very strong financial backing, thus enabling them to enlarge their facilities as their business increases. They have already gone into large new shops fully equipped with a fine line of machine tools adapted to the specialties which this company has taken up and the entire shop is electrically driven.

MORTON & SMITH.

Messrs. D. G. Morton and Julian C. Smith, both of Baltimore, have formed a partnership to carry on a general engineering and contracting business, with offices in the Law Building, that city. Mr. Morton was formerly in the employ of the Southern Railway as assistant engineer of construction, and later with the B. & O. as supervisor of the Philadelphia Division. Mr. Smith has been engaged for a number of years on street railway construction work in Baltimore and Washington as assistant to Mr. A. N. Connett, and was superintendent of the Metropolitan Conduit electric road in the latter city. The new concern will make a specialty of electric railways, but will undertake electric lighting and other work.

ADVERTISERS' HINTS

THE C. McINTIRE COMPANY, 13 Franklin street, Newark, N. J., continue to supply the large demand for their patent connectors, terminals, fuse wire, links and strips.

DIEHL MANUFACTURING COMPANY, Elizabethport, N. J., are furnishing the Diehl electric motors directly coupled to the Wing, Blackman and American Blower Co.'s exhaust fans. They are wound for any direct arc or incandescent current and are furnished with three-speed regulators.

THE C & C ELECTRIC COMPANY, 143 Liberty street, New York, direct notice to their apparatus for small isolated lighting plants and also to their C & C 4-pole combinations for all direct connected power work.

NON-SPARKING, FLEXIBLE COMMUTATOR BRUSHES are manufactured by Charles Wirt, 1028 Filbert street, Philadelphia.

THE NORTHERN ELECTRIC MANUFACTURING COMPANY, Madison, Wis., have been devoting special attention to direct-connection of motors upon all kinds of machinery. Their spherical steel invertible type is particularly adapted to this service.

THE NATIONAL PIPE BENDING COMPANY, New Haven, Conn., have sold over 700,000 horse-power of the National feed water heaters during the last ten years, and they may justly be proud of such a record.

HAMMACHER, SCHLEMMER & CO., 209 Bowery, New York, are American agents for Felten & Guilleaume's steel music wire, for which they claim high tensile strength and absolute uniformity. They carry every kind of spring wire.

THE STANDARD THERMOMETER COMPANY, Peabody, Mass., have recently brought out the Upton long-burning arc lamp for direct current, low potential circuits. Among the advantages they claim for it are no mechanism, no parts to gum or wear, no shadow, no carbon and no guide rods to clean and polish.

FRED M. LOCKE, Victor, N. Y., is manufacturing a large variety of insulators of china and glass for all purposes. These insulators have been tested up to 70,000 volts and he has received some strong testimonials as to their efficiency.

RILEY BROS., 16 Beekman street, New York, are exploiting their new kineoptoscope for depicting every movement of actual life on a screen. Besides these they carry a full line of magic lanterns and all the accessories pertaining thereto.

THE GENERAL ELECTRIC COMPANY publish a table illustrative of the application of electric transmission in power work and show very clearly the enormous scope of their installation in this field.

THE AMERICAN TECHNICAL BOOK COMPANY make a very advantageous offer to those desiring to secure some valuable work in electricity.

NEW YORK NOTES.

COLONEL BOOKER, of the Phœnix Carbon Manufacturing Company, of St. Louis, Mo., has been in the East for the past week, renewing his many friendships, and making many new ones.

THE GOULDS MANUFACTURING COMPANY, 16 Murray street, New York City, have issued a very neat little pamphlet, tastefully illustrated, in which the good points of their triplex electric pumps are cleverly pointed out. The increased use of such appliances is large and remarkable.

HUEBEL & MANGER, 278 Graham street, Brooklyn, have sent us one of their combined pin cushions, thimble holders and paper weights. It illustrates the variety of metal work which Huebel & Manger are making outside of that which is purely electrical. The present device is ornamental in appearance and extremely useful, and with the exception of the thimble holder is an adjunct to a business man's desk, or omitting the function of a paper weight it will be found useful in the household.

THE FUEL ECONOMIZER CO., of Matteawan, N. Y., will be glad to send to those interested the pamphlet on their economizer, which has now been adapted to upwards of 150,000 boilers in Europe and America. It is profusely illustrated, the pictures including a reproduction in colors of the apparatus in actual use. It enters fully into the use and benefit of the economizer, explains the details and gives a variety of data as to the methods of operation. Different arrangements are shown, and testimonials are given from several users, while the list of large plants is very long. One interesting section is that devoted to the saving effected by the economizer, accompanied by two tables of percentage of saving, which are nothing short of astounding.

MR. D. G. SCOTT, who for some time past has been connected with the American Electrical Works, is now representing in New York City the Crefeld Electrical Works of Boston. He covers this city and vicinity from his headquarters at 136 Liberty street, and will be glad of an opportunity to quote prices on all the Crefeld wires to his friends and all others needing such supplies. He believes that these wires should win a large market by reason of their quality and moderate price.

"TELEPHONE SERVICE AT WHOLESALE" is the title of an interesting pamphlet on the private branch exchange system of the New York Telephone Company. It shows very clearly how, for a moderate sum, the subscriber by this service can several times increase the efficiency and flexibility of his telephone line. It also points out the uses and advantages for such places as large apartment houses.

MR. E. CALDWELL, well known in electrical and street railway fields as a conscientious and successful journalist, has been called to the management of the Railway Advertising Company, which controls the car advertising in a great many cities and handles that for the big Metropolitan system in New York.

BALL & WOOD CO., who have won such an enviable reputation for their engines as to stand now in the very foremost rank for engines of moderate up to high speed, have taken new and larger offices in the Beard Building, 120 Liberty street, and will enter upon occupancy on February 1.

THE ALEXANDER-CHAMBERLAIN ELECTRIC CO., of 36 West Twenty-second street, New York City, has issued a couple of very pretty colored paper weights illustrative of the Siegel-Cooper "Big Store," and of the electric fountain that ornaments the ground floor.

JOSEPH DIXON CRUCIBLE COMPANY have sent us a beautiful box of pencils, with the compliments of the season, and we now use one appropriately, to indite a line in praise of their generosity and of the excellent quality of all their goods —bar none.

NEW ENGLAND NOTES

WILLIAMS, COUCH & WHITMAN, of 196 Summer street, Boston, have dissolved their firm by mutual consent, and the business will be continued by P. L. Whitman and S. H. Couch, under the firm name of Whitman & Couch, who are in line for active work in the electrical field and ask for a continuance of the old patronage.

MR. SAMUEL H. COUCH, of the firm of Whitman & Couch, of Boston, is at present traveling in the West in the interests of his firm, and will visit most of the independent telephone exchanges before his return. Whitman & Couch are sole selling agents in the United States for the Ericsson Swedish microphone, and have installed a large quantity of their telephones in many of the independent exchanges, railroad shops, office buildings, etc.

MR. G. W. DODGE, secretary of the Consolidated Insulated Tube Company, of Boston, informs us that their factory was recently destroyed by fire, but that they are getting into shape again as rapidly as possible.

THE COUNTIES OF OCEAN AND MONMOUTH, New Jersey, have just awarded the contract for a bridge, between Point Pleasant and Manasquan, to the Berlin Iron Bridge Co., of East Berlin, Conn. This bridge will be one of the longest highway bridges in the United States and is to be 1,910 feet in length. The Secretary of War has ordered a draw span in it, which will give two clear openings, one of 45 feet and the other of 50 feet. The Berlin Company's contract includes the substructure as well as the superstructure for the bridge.

THE PHILLIPS INSULATED WIRE COMPANY, Pawtucket, R. I., have gotten out a very neat calendar for 1897 setting forth the merits of the famous "O. K." line and house wires. On the back of the calendar is a table of weights and measurements to facilitate the convenience of those desiring to order wire by it. They can tell at a glance just how much they need.

WESTERN NOTES

THE METROPOLITAN ELECTRIC COMPANY, of Chicago, has been given the General Western Agency for the Alcatrez electrical compound. This will interest all consumers of electrical compounds, and those not now using the Alcatrez will do well to give it a trial as it has been proved more than satisfactory. It will not scale, crack or burn, adheres tenaciously, and is proof against the action of the elements. The compound is made from the celebrated Alcatrez asphalt, and possesses many points of superiority.

THE ELECTRICAL ENGINEERING COMPANY, 311 Second avenue, South Minneapolis, Minn., have issued as their calendar for 1897 one of the most convenient and valuable memorandum books which we have received. It contains not only space for memoranda during the entire year of 1897, but contains also a yearly calendar for both 1897 and 1898, a table of over 300 cities of the United States, with their population, and another table showing the population of the individual States. Two pages are devoted to the signals of the weather bureau, and another page is devoted to the values of foreign coins in United States money. Then there are interest laws of all the States, and some rules for computing interest in a very handy fashion; two pages are devoted to information covering the United States postal laws, and one page to weights and measures. One contains a copper wire table and another a universal wiring rule, and there are several other pages of interesting and valuable information. Taken as a whole it is just the sort of a pocket book that everybody will find very useful at some time during the year.

UPTON ARCS.—The 100 and 150 hour direct current constant potential arc lamp is rapidly securing exclusive control of this particular field of arc lighting. The Electric Appliance Company as general Western agents for the Upton arc lamp, are glad to report that they will soon be able to supply their customers with a long-burning Upton arc lamp, which has many original features, the particular one being the entire absence of feeding or regulating mechanism. The experimental lamps turned out up to date have given splendid results.

THE ADVANCE ELECTRIC COMPANY is the recent successor of the late firm of McCurdy & Smith, and is situated in their old stand, 94 and 96 North Meridian street, Indianapolis, Ind., and is an incorporated stock company. Its officers are D. D. Smith, president; Harry B. Marsh, secretary and engineer; Charles H. Talmage, treasurer. This company has just put in a select stock of goods, and is prepared to do a wholesale, retail and construction business. Mr. Smith, of the late firm, has been retained in the management of the new.

THE BROOKS-FOLLIS ELECTRIC CO., of San Francisco, will hereafter supply the Pacific coast trade with the well known dynamo brushes manufactured by Charles Wirt, of Philadelphia.

MR. FRANK B. RAE, electrical engineer and expert, of Detroit, having been engaged by the city council of Des Moines. Ia., to draft plans and prepare specifications for a municipal lighting plant, has now submitted plans for a handsome station capable of supplying 500 arcs for the streets and 200 incandescents for the city hall and fire station.

KEELEY & BAURMEISTER, Randolph, Wis., are in the market for a 300-light incandescent plant. Mr. Bert C. Keeley operates the Randolph Roller Mills.

THE CARD ELECTRIC COMPANY, of Mansfield, Ohio, have issued a very neat and tasteful brochure which they entitle "A Few Testimonials." It comprises some fifty as handsome tributes of praise as we have had the good fortune to see. The Card generators, motors, automatic motor switches and work generally, receive the highest encomiums. Their apparatus has been applied to a wide variety of uses, and is found by all to be in every respect most satisfactory.

THE MISSOURI TELEPHONE MFG. CO., of St. Louis, are just completing an expensive toll line system through the central portion of Tennessee, connecting all the towns to Johnsonville and Britts Landing. This is one of the most extensive Toll Line Systems ever built in this country.

THE BIBBER-WHITE COMPANY CALENDAR for 1897, recently distributed, must prove as ornamental as useful to its possessors. The company's name is stamped in gilt letters on a small leather panel and near the bottom is inserted the calendar proper, which may be removed. Just below their name are the words, "Everything Electrical," brief but sufficient to describe their business. Since Bibber, White & Co.'s consolidation with the New England Electrical Supply Company, under the above name, they have been excellently equipped for the prompt execution of orders for "Armorite" insulated iron armored conduit, "I-T-E" circuit breakers and switches, iron clad rheostats and theatre dimmers, Crefeld wires and cables, and a full line of general electrical merchandise. They will be glad to quote lowest prices.

THE ARMORITE INTERIOR CONDUIT CO., of Detroit, Mich., manufacturing under the Cummings patents, have just issued a reduced price list of their conduits, elbows and couplings, which ought to be in the hands of every wiring contractor, architect and builder. The conduits are manufactured in sizes ranging from 13-32 to 2½ inches inside diameter.

"S.-M."—One of the most popular cut-outs sold is the "Sawyer-Man." This is a porcelain cut-out handled by the Metropolitan Electric Company of Chicago. It fills all the requirements of the underwriters, is a neat, simple, low-priced device that is giving universal satisfaction.

PHILADELPHIA NOTES.

THE S. S. WHITE DENTAL MANUFACTURING COMPANY, of Philadelphia, have issued for 1897 a memorandum calendar, which, while evidently intended for dentists particularly, is still applicable to any business. The arrangement covers the entire period of twelve months. Each page contains space devoted to each of the six days of the week, and in the upper left-hand corner is the calendar for the individual month represented. In the space devoted to each date is a single line given up to each hour of the day, from 8 a. m. to 5 p. m., so that the individual may make his engagements for the particular hour of the day without the risk of forgetting the particular time of his engagements. The pad is a convenient one and no doubt is already in large demand.

THE SOUTHERN ELECTRIC COMPANY of Baltimore after a test of the leading incandescent lamps on the market, have signed a contract to handle the Bryan-Marsh lamps exclusively.

MR. J. G. BIDDLE, Drexel Building, Philadelphia, sold 700 Weston instruments last year, and proposes to double it this year. You can help him.

The Electrical Engineer.

Vol. XXIII. FEBRUARY 3, 1897. No. 457.

THE LEWIS INSTITUTE, CHICAGO.

BY PROF. C. W. CARMAN.

THE opening of Lewis Institute on September 21, 1896, added another educational institution to the list of those developed and fostered by the wealth of a self-made American citizen. Allen C. Lewis, a citizen of Chicago, acquired a fortune, which in the hands of the trustees amounted to nearly $2,000,000. It is stated that his resolution to found such an institution was determined upon after the death of a son who had just completed a technical education. Mr. Lewis acquired his fortune and was a resident of what is known as the West Division of Chicago, the location designated in his will for the Institute. It is located very nearly at the geographical center of the city and is within a short walk of the Metropolitan and Lake Street Elevated roads, and also several surface lines.

It was after much thought and investigation that the scope of the work to be done by the Institute was determined. While there is a large field in this country for institutions devoted to the finishing of the most advanced technical education, and for research work, it was deemed most in accordance with the will of the founder to look to the "greatest good to the greatest number." Accordingly the curriculum was broadened to embrace a liberal education as well as technical work in the arts and sciences. The course covers a period of six years, beginning with the student when he is thoroughly prepared to take up high school work. Great latitude is given to the mature student, who wishes to correct the defects in a partial education.

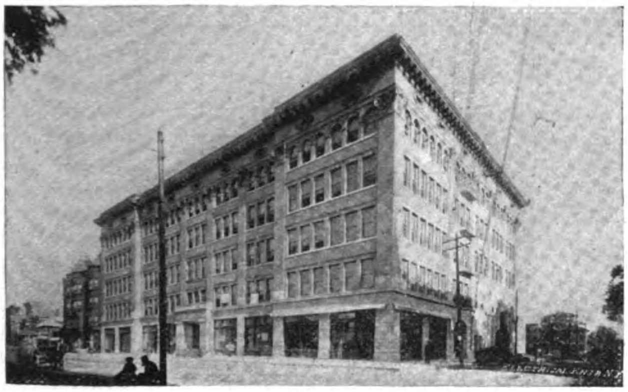

FIG. 1.—THE LEWIS INSTITUTE, CHICAGO.

A separate department for electricity has not been arranged for the reason that it is believed electricity is but a part of the general subject of physics, and that its study can be carried on as fully in that connection as in any other way. Physics is taught from the outset from a mathematical standpoint. It is believed that a student cannot take up the study of electricity with profit until he has a good fundamental knowledge of general science, algebra, geometry and trigonometry. He can then pursue the general experimental work with profit for two years, after which he may take up the subject from a technical standpoint.

The main building, Fig. 1, is 195 x 125 feet, and is six stories in height. The mechanical building is 90 x 50 feet, and two stories high.

The engines and dynamo, and boiler rooms are in the basement of the mechanical building. There are four tubular boilers, manufactured by S. I. Pope & Son. The engine room, Fig. 2, contains a 50 h. p. Skinner single acting engine which operates the ventilating system; a 60 k. w. Siemens & Halske generator, direct connected to a Ball & Wood compound engine; a 15 h. p. Western Electric motor, which operates the exhaust from the forge room, and a 3 h. p. Westinghouse motor, which operates the extra ventilating fan for the auditorium.

The first floor of the mechanical building is used for general instruction in wood-working and pattern making. A 7½ h. p. Crocker-Wheeler motor operates the lathes, an iron-cased Gibbs motor 7½ h. p. is belted to the planer, and a 4 h. p. Gibbs motor, iron-cased, is directly connected to a Barker Bros. combination circular saw. The second floor is used for metal work. The power is furnished by a 7½ h. p. Crocker-Wheeler motor.

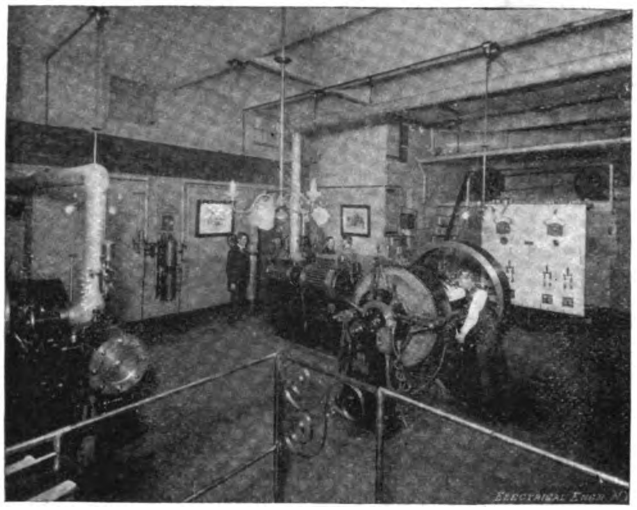

FIG. 2.—LEWIS INSTITUTE ENGINE ROOM.

The chemical department is located on the fifth floor of the main building and has three small Crocker-Wheeler motors connected to Sturtevant blowers, for the ventilation of the gas hoods. The eleven rooms at the west end of the fourth floor of the main building are occupied by the department of physics; one of these is shown in Fig. 3.

In the "General Physical Laboratory," the students' work is upon mechanics and the introduction to electrical measurements. Each table is provided with four slate-lined fuse boxes, which are connected to the switchboard by independent wires. The student prepares his apparatus on the table, after which he closes his circuits by means of flexible cord and plug switches. Five different currents may be obtained from the fuse boxes at the corners of the tables, as follows: A

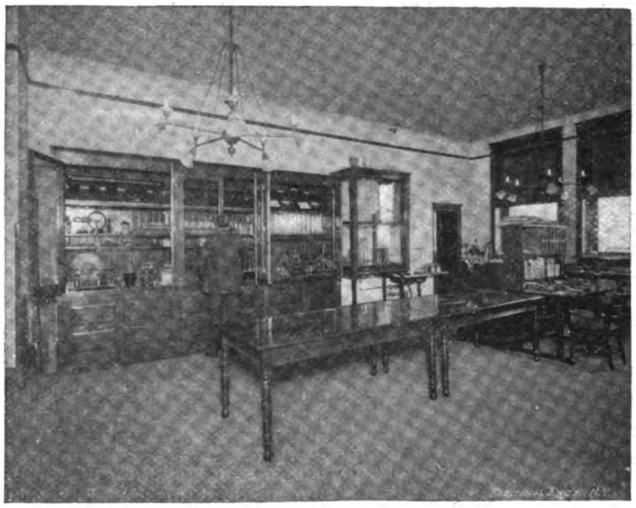

FIG. 3.—PORTION OF PHYSICAL LABORATORY.

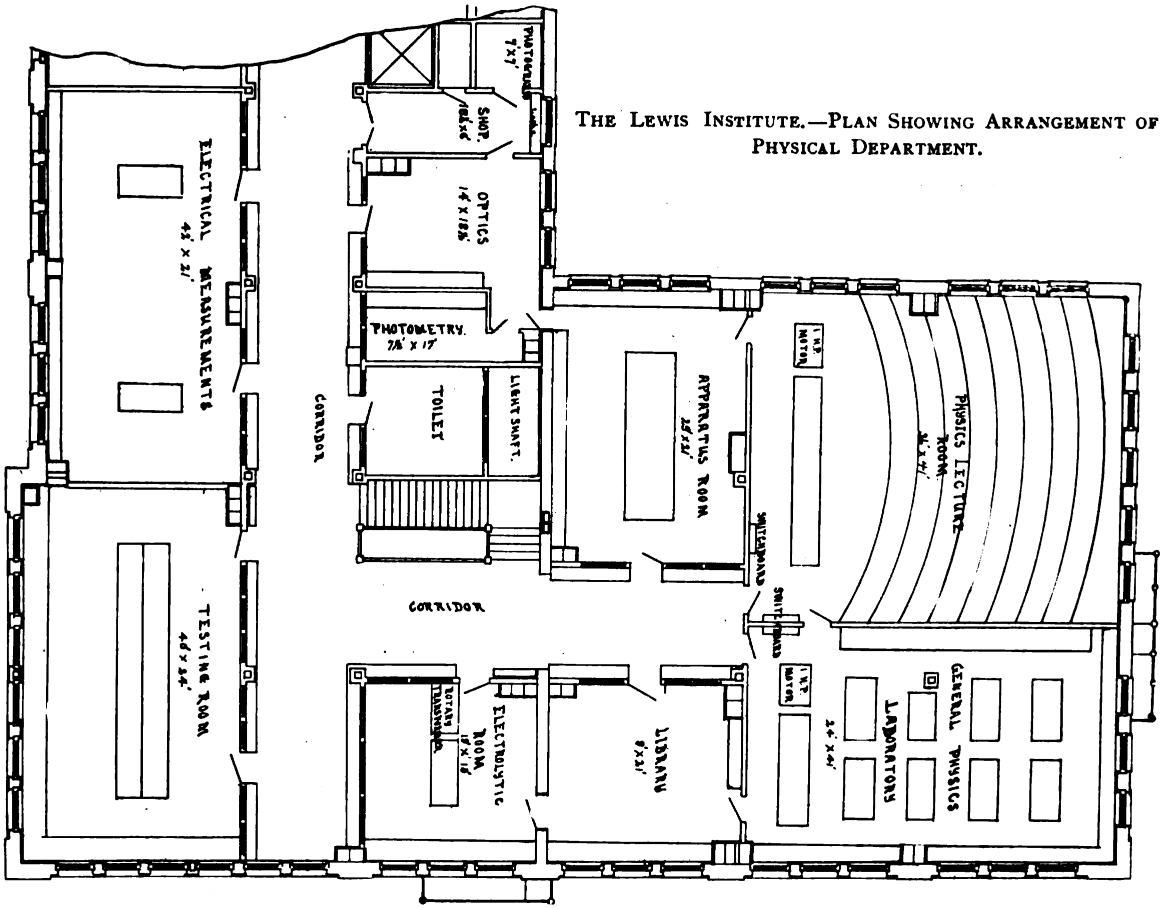
110 volt and a 5 volt direct; a 5 volt single-phase, a 5 volt two-phase and a 100 volt three-phase. Transformers are provided by means of which a variety of other voltages are readily obtained. In addition to the usual measurements in resistance, induction, etc., the student is required to do quantitative electrolytic work.

The balance room is equipped with delicate balances for general work and six quantitative balances. If desired the student may take a practical course in electroplating. The photometric room is equipped with a Lumner-Brodhun photometer, besides the usual instruments. It is intended to give special attention to commercial work. A special room is equipped for Röntgen ray work.



The Lewis Institute.—Plan Showing Arrangement of Physical Department.

The laboratories are equipped not only with apparatus from our own country, but also from several well known foreign firms as follows: Hartmann & Braun, Dr. Edelmann, Franz, Schmidt, and Haensch, Hans Heele, Nalder Bros., Elliott Bros., Ducretet & Lejeune, Carpentier, etc.

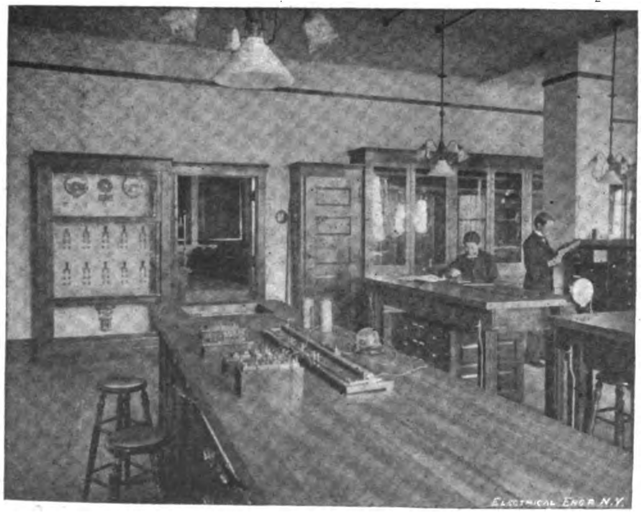


Fig. 4.—Portion of Physical Laboratory.

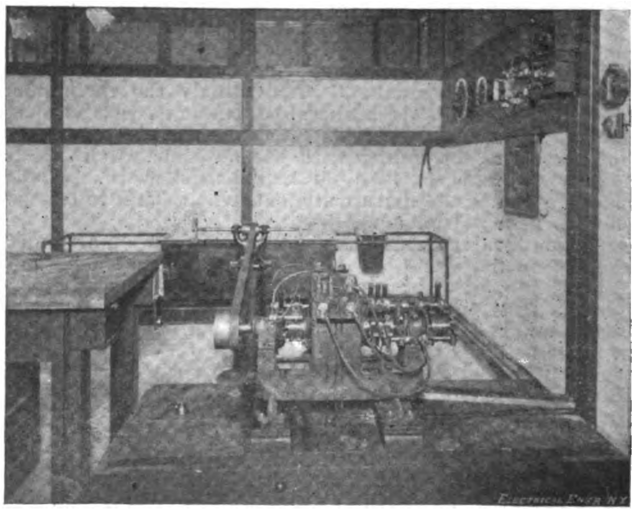

Fig. 5.—Electro Plating Bath, with Rotary Transformer.

Our engraving, Fig. 4, shows a portion of the general physics laboratory. The switchboard, seen at the left, distributes current to all the working tables. Besides the Weston volt and ammeter, it contains an automatic circuit breaker, manufactured by the Automatic Circuit Breaker Company, of Newaygo, Mich.

The wiring on the back of the switchboard, seen in the left of the previous figure, opens up as a piece of apparatus in the lecture room adjoining. Fig. 3 shows a portion of the apparatus used for lecture demonstration.

Figs. 5 and 6 show the "rotary transformer" designed for the Institute by Mr. A. Churchward, of the Excelsior Electric Company. It is really four machines in one. It is used as a motor, as a transformer of 110 volts to 5 volts direct, 110 volts to 5 volts single phase alternating, and 110 volts to 5 volts two-phase alternating current. These currents are distributed to all the testing rooms.

The four switchboards and the wiring for the 1,300 lights in the two buildings are the work of the Western Electric Company. There are fifteen different generators and motors in the buildings used in its operation, all of which may be used by students for test work.

There are about 400 students taking regular work during the day sessions, and about the same number attending class and lecture work during the evening sessions.

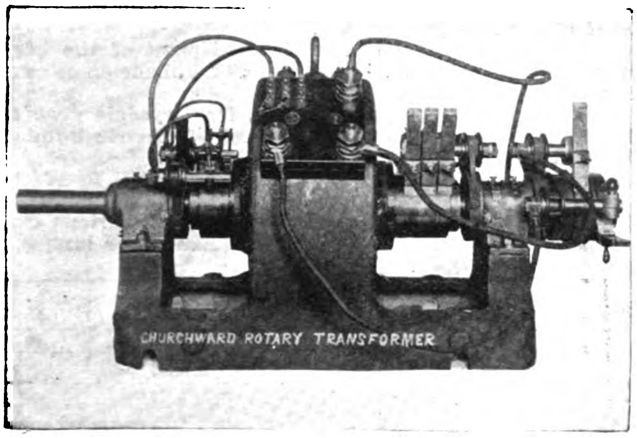

Fig. 6.—The Churchward Rotary Transformer.

Besides the regular work of the different departments, experts employed by the government are making investigations upon the impurities in the food supplies furnished to this district.

From twelve to one each day an elegantly appointed lunch room is open, where lunches, prepared under experts in domestic science and sanitation, are furnished at reasonable rates.

TORONTO, CANADA.—The plant of the Toronto Electric Light Co. has been visited by fire, alleged to be due to the short circuiting of one of the dynamos. The damage is about $75,000, covered by insurance. The city lighting was fortunately not interrupted for more than one night, several manufacturing companies shipping apparatus at once to maintain the service.

ELECTRIC LIGHTING

ELECTRICITY IN THE PENNSVLVANIA STATE HOSPITAL FOR THE INSANE, AT NORRISTOWN.

PHYSICIANS have from the very start recognized the great hygienic qualities of electric lighting, and sanitary institutions all over the world are rapidly adopting it. In retreats for the insane, especially where the exposure of naked lights has always involved danger due to the mischievous tendency of patients, the introduction of the electric light has relieved those in charge of much anxiety. We have in the past described a number of installations of this kind, but believe that a description of the plant and work performed by the electric installation at the Pennsylvania State Hospital for the Insane, at Norristown, will prove of more than ordinary interest, as it shows to what varied use an electric plant can be put in such institutions, while, at the same time, indicating the economy obtainable.

The hospital forms a collection of some twenty buildings of various sizes and at the present time accommodates 1,000 patients. The generating plant, illustrated in plan in Fig. 2, consists of three direct connected units, two of 100 k. w., with 16 x 16-inch engines, 250 revolutions, and one of 70 k. w., with a 13 x 12-inch engine, 270 revolutions. The engines are "Ideal" single cylinder non-condensing, made by the Harrisburg Foundry and Machine Works. The dynamos are multipolar, iron clad armature type, of General Electric Company's manufacture and designed for an overload of 25 per cent. above their normal rating. These machines are frequently driven at their maximum capacity, and are supplying their overload rating without abnormal heating or indication of structural weakness.

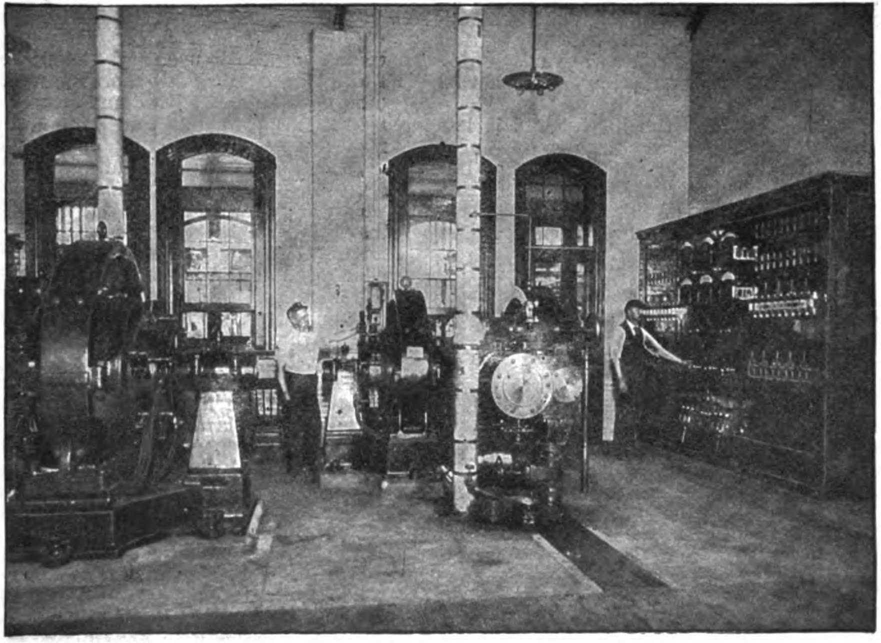

Fig. 1.—Dynamo Room, Pennsylvania State Hospital for the Insane.

The switchboard is constructed of black enamelled slate panels supported on angle irons and surrounded with a finished oak frame. The cables from the dynamos are carried under the floor in ducts and enter the board through three-pole switches, the center blade being the equalizer connection; each machine having an ammeter and voltmeter. From a switch on the board, a separate set of mains is carried through the underground ducts and tunnels to each of the different buildings, where they end at a center of distribution; from these points, pressure wires return to the board where they can be connected to a pilot voltmeter through a multiple point switch. Each circuit leaving the board is provided with a shunt and these connected to a switch and ammeter; the arrangement permitting pressure and current readings being made for any building or circuit at will. The power circuits are separate from the lighting mains, but are similarly connected to the board. All instruments are of the Weston illuminated dial pattern and specially designed for the work.

With the exception of the three steam engines operating the dynamos, the entire power of the institution is supplied by Crocker-Wheeler motors, the different departments being operated by individual motors, as follows: Printing office, 10 h. p.; bakery, 15 h. p.; carpenter and machine shops, 25 h. p.; laundry, general machinery, 40 h. p.; drying racks, 25 h. p. Although these motors have a constantly varying load and are in use at the same time as the lighting, the regulation of the engines and dynamos is so perfect that the variation of the voltmeters is never over one-quarter of one volt, and this only under unusual conditions.

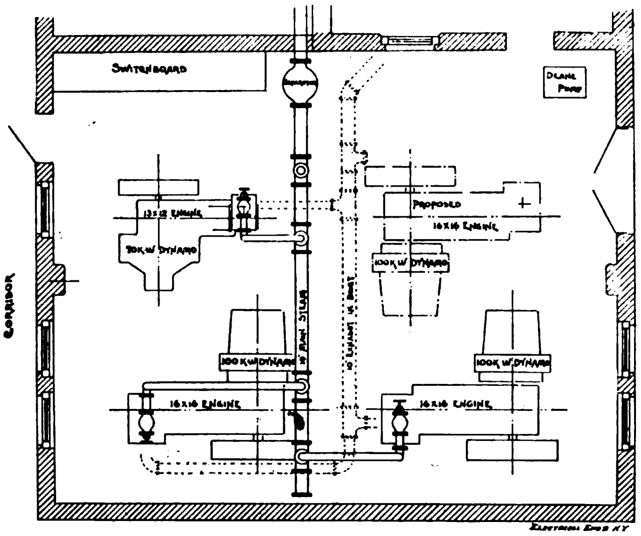

Fig. 2.—Engine and Dynamo Room, Pennsylvania State Hospital.

Owing to the great area covered by the institution, it has been impractical to utilize steam power at a number of places where it is desirable for ventilation and other purposes, but the results obtained from electric power have been so thoroughly satisfactory that plans are in preparation for an extensive application of motors throughout the property. The installation of electrical equipment has allowed improvements in the service of the departments, that under former methods were impossible, and now current is not only used for lighting and power and heating food in the wards for the sick, but its applications to the purposes of the surgical and medical staff are apparently unlimited.

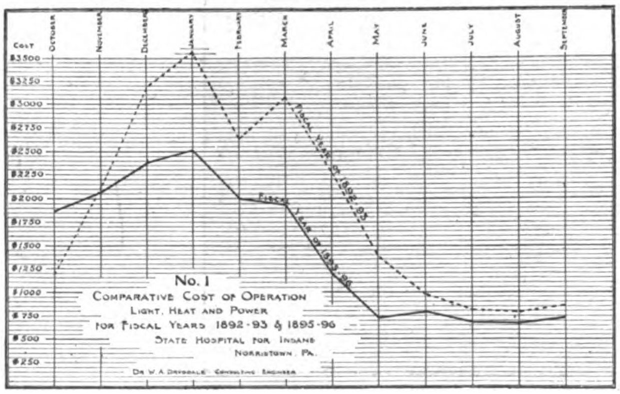

Fig. 3.

The wiring throughout the institution is carried in molding and in brass and iron-armored tubing as best suited to the particular location. With the exception of the Administration Building, the wiring is carried on the surface, and, as far as possible, out of reach of the patients, and, while no damage has ever been reported, the entire system is daily inspected. All circuits are controlled by switches, those in places accessible to the inmates being of the "Cutter" lock type and the general circuits by knife blade switches placed in locked cabinets. Each ward is provided with two centers of distribution and both the "Watch" and "General" lighting circuits are in duplicate, and so arranged that an accident to any circuit or destruction of one of the centers will not leave the ward in darkness. All the buildings are connected by large vaulted brick corridors and under these are the tunnels and ducts through which the heating, gas, water and other service pipes are carried. The mains to the various buildings follow these ducts, and are supported on glass and porcelain insulators; the construction being as carefully designed as if exposed to the weather.

The entire electrical and mechanical plant of the hospital was laid out by Dr. W. A. Drysdale, of Philadelphia, consulting engineer to the institution.

In his annual report on the plant, Dr. Drysdale gives some highly interesting data as to the cost of electric lighting as compared with that of gas, formerly used.

Formerly the lighting was furnished by 1,927 five-foot gas burners, and the steam engines developed 55 horse-power. There are now 2,354 incandescent lamps of various candle-powers (equivalent to 2,437 sixteen-candle-power lamps), and two arc lamps in use, and the power is supplied by electric motors aggregating 110 horse-power.

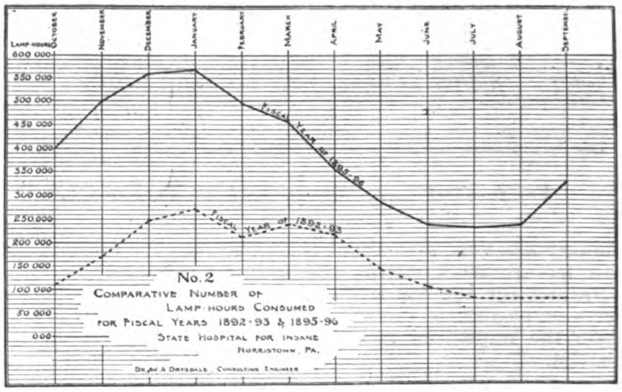

Fig. 4.

The cost of light, heat and power for the year 1892-93, including gas, coal, oils and supplies, was $22,814.63, a cost of 1.29 cents per lamp hour. The cost of light, heat and power for the year 1895-96, including lamp renewals, gas (for heating), coal, oils, extra attendance and supplies, was $17,680.28, a cost of 38 hundredths of one cent per lamp hour. A graphic illustration of these costs is given on diagram Fig. 3, the horizontal lines representing costs and the vertical the different months of the years.

While the figures show a reduction of $5,134.35 in the operating expenses, they give no indication of the relation of the costs to the work performed; and to enable a comparison to be made, the lighting and power of the two years has been reduced to a basis of lamp hours (i. e., the amount required to maintain one five-foot gas burner, or one sixteen-candle-power electric lamp for one hour. When reduced to this basis, the work performed during the year 1892-93 represents 1,768,416 lamp hours, and during the year 1895-96 a total of 4,653,040 lamp hours—an increase in the work obtained of 263 per cent., with a reduction of 22½ per cent. in operating expenses. Diagram Fig. 4 represents the work performed during the two years; the horizontal lines being lamp hours, and the vertical the months of the year.

An examination of the two diagrams will convey a much better idea of what has been accomplished than words or figures, and conclusively demonstrates that the introduction of electric light and power, aside from all other advantages, has more than justified the cost of installation, and proved one of the most, if not the most, profitable improvements undertaken by the institution.

THE ENCLOSED ARC LIGHT.—II.

BY L. B. MARKS, M. M. E.

THE next step in the development of the enclosed arc light gave us the method and devices which are in successful use at the present time. Before taking up this branch of the subject, I shall submit to you a short report of life tests and experimental investigations, made with the old equipment which I have already shown you. The length of cylinder used was 16½ centimeters over all, the diameter of body 7⅝ centimeters, and the capacity ⅝ liters. The memoranda on effect of introducing various ingredients into the carbons, and on the influence of different gases on the arc are digested from elaborate notes and observations and are given rather with the idea of recording the general results than analyzing the details of each experiment. I shall also refer to other phenomena observed in using this cylinder, especially that known as "building" of the negative electrode.

Life Tests Cylinder with Valved Cap.—In Table I. the comparative measurements are recorded showing the life of the upper and lower carbons, respectively, for different sized openings in the metallic cap or plug. It will be noted that in the first test the diameter of the opening in the plug is only a shade greater than that of the upper carbon; in next to the last test the diameter is 6.85 millimetres larger than that of the carbon, while in the last test the plug is removed from the cylinder. As is very natural, the line decreases rapidly as the opening is enlarged, but as shown in the tests, does not necessarily vary directly with the size of the opening. In each of the tests recorded, the arc was started at a point slightly higher than the center of the bulb. It will also be seen that the life of the negative decreases much more rapidly than that of the positive, as the ingress of oxygen into the enclosure is increased. Thus when the positive carbon fitted tightly in the opening in the plug, $\frac{\text{life } (+)}{\text{life } (-)} = \frac{2.222}{.102} = 21.78$

Table I.—Life Tests. Cylinder with Valved Cap.
Carbons 11.11 mm. (7-16 in.) in diameter.

Diameter of hole in valved cap (in mm.)	Mean current. (amperes.)	Mean arc tension (volts.)	Mean energy. (watts.)	Consumption (+) carbon p. h. in (mm.)	Consumption (—) carbon p. h. (in mm.)
11.905	7.96	62.9	500.68	1.988	.312
12.7	7.99	62.98	502.21	1.905	.424
14.287	7.99	62.8	501.77	2.328	.424
17.46	8.00	61.1	496.80	2.753	.534
28.575	7.94	62.8	498.69	11.556	8.077

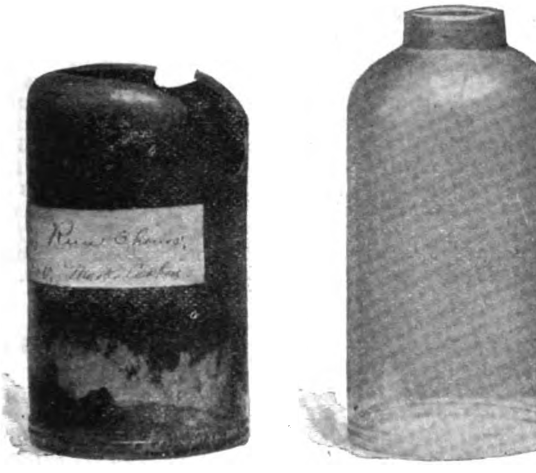

Fig. 3.—Blackening at Low Voltage of Arc.

When the diameter of the opening in the plug was 6.35 mm. larger than that of the carbon, the excess of oxygen due to enlarged opening attacked the negative vastly more than the positive, resulting in $\frac{\text{life } (+)}{\text{life } (-)} = \frac{2.753}{.534} = 5.16.$

When the plug was omitted, the disparity became still greater and $\frac{\text{life } (+)}{\text{life } (-)} = \frac{11.556}{8.077} = 1.43.$

In Table II. I give the results of life tests in which the position of the arc was shifted from the extreme upper part to the extreme bottom of the cylinder. It will be noted that in the first test the negative was 158.75 mm. long while in the last it was only 66.116 mm. long. As the arc shifts in position from the top towards the bottom of the cylinder the life of the carbons decreases. This is due to strengthening of the convection currents as the negative burns away and consequent increase in admission of oxygen.

Table II.—Life Tests. Cylinder with Valved Cap.
Carbons 11.11 mm. (7-16 in.) in diameter; mean current, 8 amperes; mean arc tension, 63 volts.

Position of arc in cylinder.	Mean length (—) carbon. (in millim.)	Consumption of (+) carbon p. h. (in millim.)	Consumption of (—) carbon p. h. (in millim.)
Near top	158.75	2.362	.266
Between center and top	140.97	2.921	.266
At center	123.19	3.683	.393
Between center and bottom	95.25	3.973	.660
Near bottom	66.12	4.825	.965

Influence of the Surrounding Atmosphere and of the Constituency of the Electrodes.—First, hydrogen; introduced through a hole in the positive carbon; tests made through range of 6 to 11 amperes and 60 to 77 volts at the arc, voltage of the mains being practically constant and equal to 120. There was only a slight variation in the length of the arc throughout this range, the maximum length being 2.36 mm. and the minimum 1.65 mm. Thus it will be seen that the presence of hydrogen tends to increase the resistance of the arc greatly, thereby shortening it to about one-sixth its normal length in carbon gas, for the same current and voltage. The arc is also unsteady, and the light cut down to a large extent. It may be noted here that when moisture has settled in the bulb or carbons of an ordinary enclosed arc, there is a tendency towards reproduction of the above conditions, the

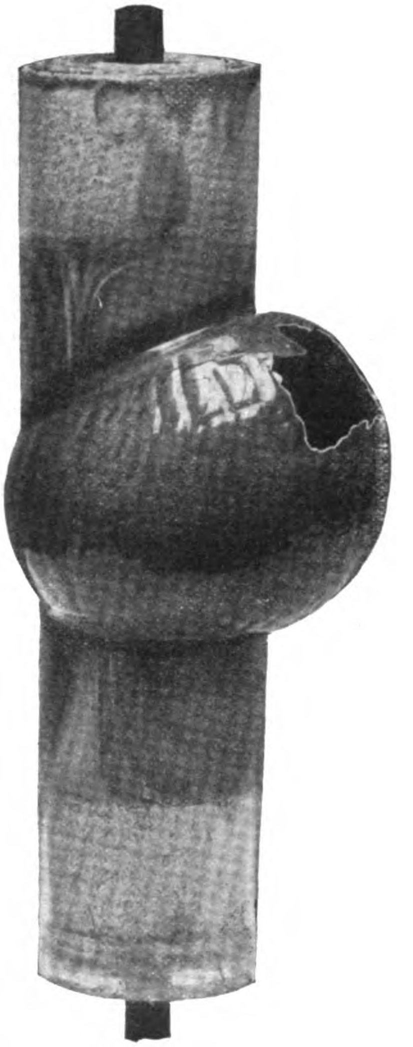

Fig. 2.—Result of Enclosing the Arc Air Tight.

arc in such case being very short and unsteady at start and remaining so until the moisture has been dissipated.

Second, iodine; tincture of iodine placed in a small glass immersed in sand in bottom of cylinder. Current ranged from 5.5 to 8 amperes in different tests; voltage of arc from 70 to 75; voltage of mains 120; minimum length of arc 2.79 mm., maximum, 3.17 mm. It will be noted that the action of iodine is somewhat similar to that of hydrogen, the tendency being to increase the resistance of the arc and thereby shorten the latter; the effect, however, is not as marked as in the last case.

Third, chlorine; generated in the usual way and admitted to the cylinder from the bottom through a tube. Current ranged from 2.3 amperes to 8 amperes; voltage of the arc from 80 to 96 volts; length of arc from 6.35 mm. to 36.32 mm. It will be noted that in this case the results are entirely different than in the other two. The presence of chlorine reduced the resistance of the arc greatly, so that at 2.4 amperes and 80 volts the length was 6.34 mm., while at 8 amperes and 96 volts the length was over 36 mm.

Following are some of the results with impregnated carbons.

First, sodium carbonate ($NaCO_3$). Carbons which had been soaked over night in a solution of sodium carbonate, gave a steady arc for 2 hours at 8.5 amperes and 55 volts, after which for the same length of arc, the voltage increased appreciably until the effect of the solution disappeared entirely. The deposit on inner wall of cylinder after two hours was thick and had a tendency to crack the glass. The ordinary foreign and American cored carbons have sodium carbonate in their cores and give similar results to the above, though less marked.

Second, ammonium chloride (NH_4Cl). When carbons were saturated with ammonium chloride the arc was over twice as long at same voltage as in last case. Ammonium chloride evaporates at a comparatively low temperature, but decreases the resistance of the arc and leaves practically no deposit in the bulb. The lower part of the cylinder became coated with condensed vapor shortly after the arc was started, but as soon as the heat became intense enough, this formation was dissipated and the glass became perfectly clear. At the end of a 4 hours' run the extreme lower end of the cylinder was slightly coated with a yellowish green band.

Third, magnesium oxide (MgO). Magnesium carbonate when used as a core of the negative carbon, is converted by heat to magnesium oxide, carbonic acid gas CO_2, gas being driven off. The CO_2 is dissociated at a comparatively low temperature and, as may be expected, the voltage necessary for a steady arc is quite low. For 15 minutes the p. d. of the arc ranged from 40 to 45 volts with a current of 8 amperes, the arc meanwhile being quite steady; the area of the crater was about 8 square millimetres. The decomposition of the magnesium carbonate was marked by a series of slight and almost inaudible explosions; finally a hard bead of MgO was left at the tip of the negative. This bead was extremely refractory; it did not succumb to the heat of the arc, but persisted as an incandescent globule from which the arc stream seemed to issue. The p. d. of the arc varied from 44 to 50 volts at 8.5 amperes, the arc being quite steady for almost an hour; there was no appreciable coating on the internal surface of the cylinder. Occasionally a slightly greenish hue was noticeable in the arc.

For comparative purposes different types of carbon points, all practically alike as to purity, but varying in granular structure, were tried. The following combinations were tested: First, lamp-black molded; second, lamp-black squirted; third, gas-black molded; fourth, gas-black squirted; fifth, petroleum coke molded; sixth, petroleum coke squirted. The results were practically the same for all structures of carbon.

The tabulated data show that for the same current and length of arc, the p. d. at the carbon points will depend upon the surrounding atmosphere as well as on the constituency of the electrodes. The fall of potential from one carbon to the other follows, in general, the well known law, the major portion of the drop (for short steady arc) being from the positive carbon to the arc stream. There was one experiment, however, which gave very surprising results and which is deemed worthy of mention in this connection as the phenomena observed seemed to constitute an exception to the rule.

A steel nail was driven into a hollow negative carbon as a substitute for the core. The sharp end of the nail projected just above the tip of the carbon. A solid positive carbon was used. When current was passed there were brilliant scincillations due to incandescent steel, followed by fumes which coated the internal wall of the chamber with a dark reddish deposit of iron oxide. A molton steel ball soon formed in the concavity at the tip of the negative. The length of the arc was between 3 and 4 millimetres, current being from 8 to 9 amperes and the p. d. at the arc varying from 20 to 30 volts. The negative was intensely hot, while the positive was comparatively cool. The area of the crater in the positive was about 1 square millimetre or about one-eighth of that in the other cases. The arc, expanded in cross section at the negative and tapering at the positive, darted from point to point across the projecting surface of the upper carbon, sometimes jumping a distance of 5 or 6 millimetres to select a path; meanwhile the negative glowed with constant brilliancy. The arc always played from the side of the molten steel ball, the latter often spinning like a top, seemingly in unison with the arc. The results of this experiment, seemed to indicate an accidental reversal of current but subsequent tests showed that no such reversal occurred.

Blackening of the Internal Surface of Enclosure.—Before taking up the analysis of the latest development of the art let us pause for a few moments and examine into the underlying principles governing the successful operation of enclosed arcs of to-day. Let us start out with the operation of an enclosed arc within an airtight compartment to which the outside atmosphere has absolutely no means of communication. The photograph I give herewith, Fig. 2, represents such a structure and illustrates the results which follow the passage of current. I shall show you the stereopticon view of the apparatus on the screen later on. You will note that the glass which was originally cylindrical, now has a large spherical protuberance at the side. You will also note that the chamber is coated on the inside with a heavy black deposit. This apparatus was originally air-tight and the carbons in contact.

Current was passed so as to form an arc and in due time the length of this arc increased from 0 to about 9 millimetres as the carbons consumed. The bulb began to blacken after the oxygen contained in it went into chemical combination with the carbon vapor of the arc stream. Such a result is natural, as the disintegration of carbon must go on as long as the arc plays; the carbon, having no substance with which to combine, is thrown off in the form of a black soot on the internal wall of the chamber. Moreover as in this case, when there are no means of exit for the expanded gases, the pressure is sometimes sufficient to distend and rupture the envelope.

Although the blackening of the internal wall of the chamber always follows the operation of a carbon in an airtight enclosure, the same discoloration may occur under other circumstances when the enclosure is not airtight or even nearly so. This second case is illustrated in a cylinder in which the annular space around the entering carbon permitted of access of oxygen to the enclosure. The blackening was due to a large current and a short arc. In the photograph, Fig. 3, I have placed a clear cylinder alongside of the other for comparative purposes. You will note that the deposit is inky in color and quite uniformly distributed over the surface of the glass. In this case the carbons were burned for three hours at a current of 18 amperes, the arc tension being 30 volts. The amount of impurity in the carbons was inappreciable.

LIGHT; ITS DISTRIBUTION AND DIFFUSION AS RELATED TO QUALITY AND EFFICIENCY.[1]—I.

BY E. LEAVENWORTH ELLIOTT.

We may, for convenience, divide the subject of artificial lighting into five different sections, viz: (1) Intensity, or brilliancy; (2) distribution; (3) diffusion; (4) quality; (5) efficiency.

The average brilliancy of illumination which will be most desirable, will, of course, vary somewhat with the use to which it is to be put. A "dim religious light," that would be very satisfactory in a church would be wholly inadequate for a library, and equally unsuitable for a ballroom. For general purposes, it is safe to say that the intensity must nowhere be less than one candle-foot, and twice this brilliancy is undoubtedly better. With our present means of producing intense light it is quite possible to exceed the limits of effective illumination and produce a glaring intensity which is a serious error both from the æsthetic and physiological standpoints.

The distribution of light involves two quite distinct problems, viz.: (1) The distribution of the several units into which the general source is to be divided, and (2) the distribution of the rays from the individual units. The first of these problems contains as a determining factor the luminosity or "candle-power" of the light units adopted. The determining factor in the second problem is the nature of the light-source itself. The result desired is in nearly all cases the same; that is, to secure a uniform brilliancy on a certain plane, or within a given space. A room uniformly lighted, even though comparatively dim, gives an effect of much better illumination than where there is great brilliancy at some points and comparative darkness at another; the darker parts, even though actually light enough, appear dark by contrast, while the lighter parts are dazzling. For this reason naked lights of any kind are to be avoided, since they must appear as dazzling points, in contrast with the general illumination.

---

[1] Abstract of a paper read before the New York Electrical Society.

Light is commonly defined in the text-books as "that form of energy which is capable of affecting the optic nerve." Any stimulus of this nerve is translated by the brain into the sensation of vision. We may "see" objects, particularly stars, without the intervention of ether waves; and we may fail entirely to interpret the effect when ether waves impinge upon the retina; as, for example, in the case of "color blindness." The theory of lighting is, therefore, associated with psychology and physiology quite as much as with physics. Thus all the methods of photometry depend upon the mental comparison and judgment of the sensation of vision.

Aside from difference in intensity, light produces many different effects upon the optic nerves and their centers in the brain. These different impressions we ascribe to difference in the quality of the light. Thus, "hard light," "cold light," "mellow light," "ambient light," etc., designate various qualities. Quality in light is exactly analogous to timbre, or, quality in sound, which is likewise independent of intensity. The most obvious differnces in quality are plainly those called color. But color is by no means the element of quality. The proportion of invisible rays and the state of diffusion, are highly important factors, but on account of not being directly visible, they have been generally overlooked, and are but imperfectly understood.

It may be safely said that all rays on either side of the most plainly visible part of the spectrum are injurious to the eyes. The light of the electric light has a very large excess of violet and ultra-violet rays, which injures the quality very greatly. Gas flames, on the other hand, have an excess of infra-red or radiant heat rays, which likewise injure the quality. I have heard the same charge made against the Welsbach light, but have not yet been able to verify it. The absorption of these extra-spectral and injurious rays by suitable transparent screens is undoubtedly feasible, but seems never to have been even suggested.

The importance of diffusion has also been greatly neglected. We must keep in mind the distinction between diffusion and distribution. Distribution refers to the instrinsic brilliancy of illumination at every point in the given space; diffusion refers to the number of rays that cross each point. The amount of diffusion is shown by the character of the shadow. Daylight on a cloudy day may be considered perfectly diffused; it produces no shadows whatever. The light from the electric arc is least diffused, since it emanates from a very small surface; the shadows cast by it have almost perfectly sharp outlines. It is largely due to its high state of diffusion that daylight, though vastly more intense than any artificial illumination, is the easiest of all lights on the eyes. The eyes should be subjected as little as possible to the direct rays from any light-source. It is a common and serious mistake, in case of weak eyes or overstrained eyes, to reduce the intensity of the light, instead of increasing the diffusion. The eye is made to receive light, and, like any other organ, is strengthened by use. To attempt to strengthen weak eyes by reducing the light, is like attempting to strengthen your arm by putting it in a sling. Farmers, who are continually out in the brilliant sunlight, are almost entirely free from weak eyes. An abundance of light of the right quality is what the eye needs.

The efficiency of a light-source is the ratio of the energy given out as light, to the total energy consumed. All our present means of producing light are wasteful in the extreme, the efficiency probably never exceeding 5 per cent,, and half that being nearer the average. The production of light is one of the dreams of the physicist and will probably some day be realized. But while we are compelled to use the present wasteful methods of generating light, it is the more important that care be taken to secure the greatest possible illumination from any given source.

The dynamo has been brought to marvelous perfection. But while electrical engineers will argue and labor for the difference in 2 per cent. in the efficiency of the dynamo, they will not give so much as a thought to the waste of half the light after it is produced. The promotors of incandescent gas lighting are equally inconsistent. They do no end of talking about the saving of gas by their systems, but say nothing about the absorption of a third to a half the light by the various shades and globes which they supply with their burners. In short, there has been almost a total neglect and a resulting absolute ignorance on the part of those whose business it is to know of the general principles of the utilization of artificial light. It is the chief purpose of this paper to briefly set forth these principles, and review the various attempts that have been made to apply them to practical use.

MUNICIPAL OWNERSHIP.—DEFECTS AND DANGERS.[1]

BY W. W. LOW.

THE author contended that if people would study and discuss the municipal ownership question as thoroughly as they did the financial question in our last campaign, the result would be the entertaining of a more rational view of the subject.

From an extended experience in the electric lighting enterprises he was satisfied that if this branch had been owned and operated under municipal control from the time the first light was installed to the present day, it would have been on an average far more expensive to the inhabitant than it has now been. There is hardly a franchise granted at the present day without limiting the charges for service rendered, and as long as such charges are reasonable, as long as the earnings are no more than other unlicensed enterprises, which, he contended, they are not, then municipal ownership will not be advantageous, but detrimental to the public welfare.

In case there should exist plants which owing to loose franchises should abuse their powers, it might be well to have a law such as already exists in some States, by which a reasonable charge could be determined and regulated.

The most serious objection to municipal ownership, Mr. Schuette maintained, lies in the increased opportunities and temptations offered for boodling, and the multiplied power to form and maintain rings. Given the addition to the regular city officials and employés, of all those of water works, gas works, electric light plants, telephones, telegraph, railroads, and then add, as some advocate, the saloon interest, which are also licensed institutions, the combined forces, having abundant spare time while under public pay, can and would electioneer every day in the year.

The natural result would be that this active self-interested element would exert such a political influence in our caucuses and elections, that our citizens other than the office class, would be practically disfranchised.

Mr. Schuette exhorted the association to stand in a solid phalanx ready to defend one and all against any and all unjust, unfair legislation which may be attempted against the electric light interest.

HEATING AND COOKING BY ELECTRICITY.[1]

BY GEORGE CUTTER.

AFTER giving some very interesting figures on the expenditure of current in the different applications of electrical heat for cooking and other purposes, Mr. Cutter made some excellent suggestions in regard to the encouragement and extension of the supply of current for domestic and other uses. He insisted that:

(1) Every central station manager should familiarize himself with the well-developed heating and cooking apparatus now on the market, so as to be ready to talk it to his customers.

(2) He should arrange to show the apparatus in operation so as to create a public interest in it.

(3) He should study the question of rates so as to be able to offer special inducements to a more varied use of current.

(4) He should educate his patrons to use the current economically, for therein lies the secret of expanding the use of heating apparatus.

(5) And last, but not least, he should insist on the use of devices which are efficient and whose durability is practically vouched for by the standing of the manufacturers.

J. C. KNIGHT, of Elizabethport, N. J., has been engaged as superintendent of the People's Electric Light Company, Oswego, N. Y., to succeed F. E. Pritchard.

MR. ROBT. A. L. GRAY, electrical engineer, Toronto, Can., writes us: "I have had very good results with the Data Sheets, and especially with the incandescent wiring tables."

ROENTGEN RAYS

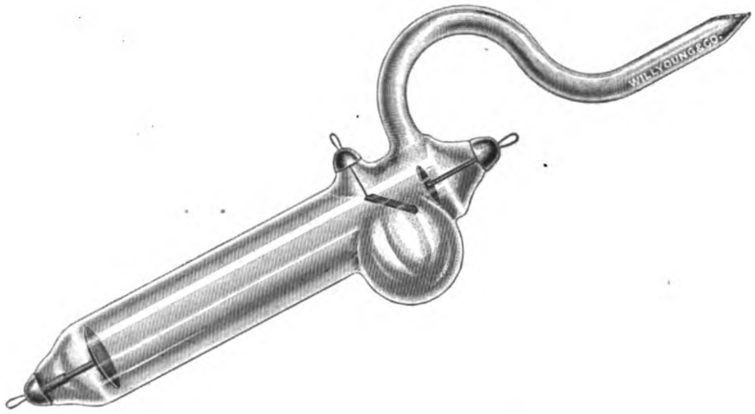
X-RAYS—APPARATUS AND METHODS.—II.

BY ELMER G. WILLYOUNG AND H. LYMAN SAYEN.

TESLA coil or induction coil—which?—Having carefully examined the results, apparatus and methods of others, all over the country, devotees some of the high frequency coil, some of the induction coil, and having made many and careful experiments with both forms of apparatus ourselves, we favor the induction coil, on account of: 1. Simplicity. 2. Ease of manipulation. 3. Cleanliness. 4. Sharpness of definition obtainable. 5. Noiselessness. 6. Less strain on tube.

Although we have diligently examined, we have yet to see results obtained by any form of apparatus superior to those made right here in Philadelphia, by Dr. Goodspeed, of the University of Pennsylvania. Dr. Stern, of the Polyclinic Hospital, ourselves, and many others who might be mentioned, and this either as regards detail, penetration, or quickness of exposure. Indeed, we may say that we have never seen results obtained with the Tesla coil that are equal in any of the above respects to the results just referred to.

The Tubes.—Many forms of tubes have been suggested. With practically no exception all tubes now in use employ as cathode a concave aluminum disc whose center of curvature is at the center of a small platinum plate (⅝ to ¾ square inch in area), the plane of the plate being inclined to the normal from center of the concave cathode. This platinum plate is sometimes made the anode, sometimes the anode is a separate plate or wire elsewhere in the tube. This form of tube is known as the "focus" tube, the cathode rays being focussed upon the platinum plate which then becomes the active source of X-rays. In the double focus tube we have two concave cathodes at opposite ends of the tube, the platinum wire reflector being in the form of a wedge with a side presented to each of the concave cathodes.



WILLYOUNG & CO.

FIG. 5.

In the use of the tube everything depends upon the vacuum, X-rays seeming to be of a heterogeneous character just as are light rays, the quality of the X-ray varying with the degree of vacuum. The higher the vacuum the more penetrating power the tube has. Hence it is well to select tubes and use different tubes for different purposes. A tube of extremely high exhaustion is best for working through the body; but with forearm, hands, feet, etc., the tube has too great penetration, the bones appearing almost equally transparent with the flesh.

The chief difficulty with most tubes is the change of vacuum which takes place in use. This is thought to be due to the occlusion of the residual gas upon the inner surface of the glass resulting in an increased vacuum. It may be partially restored by heating the tube by use of a spirit lamp or Bunsen flame. This must be very carefully done, however, to avoid cracking the tube. When the platinum reflector is used simply as an anti-cathode and the anode is aluminum a simple reversal of the discharge will prove fairly successful. Some makers have adopted the scheme practiced now for many years of blowing a small side pocket upon the tube, into which is placed phosphoric anhydride or some other chemical substance or composition absorbing moisture. When heated, this substance gives off vapor to make up for the loss; it is difficult, however, to drive off just the right amount of vapor in this way and the vacuum is liable to be made too low, in which case flesh and bone are about equally opaque. So rapid is this change of vacuum that in most cases involving over a few minutes' exposure or running of the tube, one of the above methods becomes necessary. In any case, eventual, almost complete exhaustion, seems to be the rule, and the tube must then be returned to the makers and re-exhausted. "Blacking" is another cause of decreased efficiency in the tube. It is due to deposition of platinum upon the inner surface of the tube.

The "Bowdoin" tube, shown in Fig. 5, was devised after a considerable amount of experimental work by Profs. Robinson and Hutchins, of Bowdoin College. In general design it does not differ essentially from many other forms of focus tube upon the market. The two respects in which the tube does differ from other tubes is, first, in the arrangement of electrodes, the reflector plate not being connected to the coil at all, but merely acting as an obstacle to the bombarding rays, while the anode is a disc at the end of the tube away from the cathode. This arrangement is found to perfectly and entirely prevent blackening, no matter how long the tube may be used.

The most important feature of this tube is, however, the presence upon its interior surface of a fluorescent material which has been fused into the surface of the glass. As the tube is used, this material either by the bombardment, or heating, or both, gives off just enough air or vapor to make up for the occlusion due to the natural working of the tube. The vacuum therefore tends to remain always constant. Although it seems almost absurd that one could put in just enough of this material to make up for the gas otherwise lost, yet it is a fact that these tubes remain practically unchanged in vacuum at all times, the equivalent spark length retaining its value at all times within, at the outside, a variation of 10 per cent.

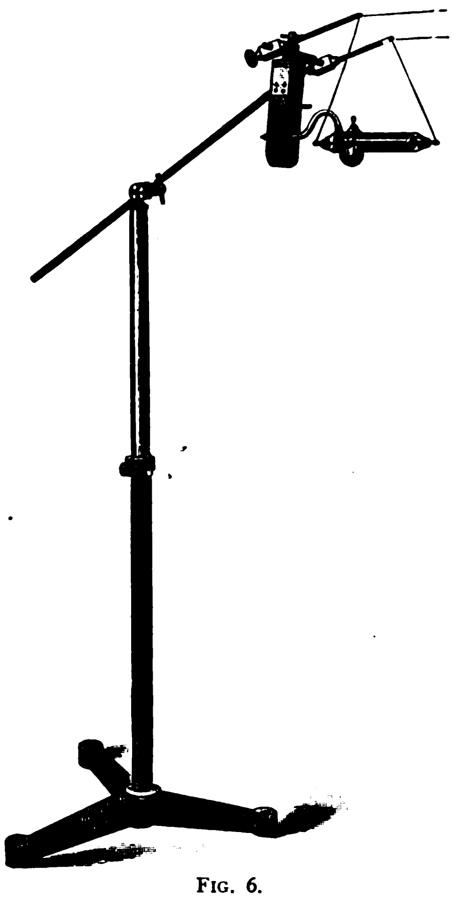


FIG. 6.

In use the tube requires no "nursing" whatever. It should always have a parallel spark gap which should be quite small, say, an inch or inch and a half, and either the primary current or the vibrator tension adjusted so as to produce only very small secondary discharge. The energy of this secondary discharge may then be immediately increased until the reflector plate shows a dull red spot of about half the size of the nail of the little finger. The tube is now in its most efficient condition, and, with a well constructed and smooth working break, may be run for an hour or two without the slightest attention. The "getting ready," as above described, takes considerably less time than the time it has taken us to describe it. Indeed, in our own work, we do not trouble to make this preliminary adjustment at all, as we make it once for all when we first begin to work with a tube and do not afterward disturb it, merely closing down the switch when starting work.

Life of Tubes.—The life of tubes in general is limited. (A) by the time required for the vacuum to become too great; hence requiring re-exhaustion. (B) by ability to stand the electrical strains.

(A) applies to all tubes so far as we know, save the Bowdoin tubes. Probably six or eight hours continuous working, or the equivalent, suffices to incapacitate the average tube. We think that even with the Bowdoin tube there is a strong tendency to eventual very high vacuum, but the time required would be very great relatively, say, ten to fifteen times that operative in the case of other types of tubes.

(B) All well made tubes (from the glass-blower's standpoint) are about equally liable to this limitation. It is probable that these strains are cumulative in their effects upon the tube, the latter gradually weakening until eventually break-down takes place with secondary discharges, much less than would have been originally required for breakdown.

The Stand.—The stand, shown in Fig. 6, has been devised by us for applied X-ray work. With it the tube may be placed in any position within a cylinder 6 feet high and 6 feet in diameter, thus making it possible to get under or over a patient, no matter what the latter's position. Rods of vulcanized fiber clamp to the stand in any position and carry the lead wires of the tube thus keeping them away from one another and from the metal of the stand. They carry little spring clips at their extremities by which the wires are caught without tieing or bending. The whole stand is of bicycle tubing and very rigid.

The Subject.—The patient should, of course, be placed in as easy a position as possible. For body pictures, hip and knee joints, etc., a recumbent position may be assumed. The plate should lie beneath and upon a stiff board backing, to avoid risk of breakage. Work upon the shoulder, neck, head, etc., may be done with the patient straddling a straight-backed chair, facing the back, and leaning the body against the back for support. The plate may be bound fast to the body by bandages.

Laws for Exposure.—Since the X-rays proceed in straight lines from (approximately) a point source, the intensity of their action varies inversely as the square of the distance from the source. Hence the time of exposure should vary directly as the thickness of the intervening substance. To apply these principles in practice take a trial picture of the hand at 5-inch distance, this being amply sufficient for good definition with such small bones. Say one minute is required for a good result. Then to take a hip joint, we estimate the thickness of the latter to be, say, ten times that of the hand. We must, therefore, expose ten minutes on account of thickness alone. But, owing to the greater distance of bones from plate, the tube must be removed much further to get definition. At least fifteen inches from the dry plate should be given; this is three times the distance used for the hand from which the times require to be as the squares of these figures or as 1 is to 9. The total exposure must, therefore, be 90 minutes. This method gives something to go by. After a little experience perhaps the most convenient thing to do is to arrange a little table, based upon previous results, and showing times and distances required for well defined results for distinctive parts of the body.

Short Exposures.—We have obtained and do regularly obtain without difficulty well defined pictures showing complete detail of the osseous structure involved in times and with distances from dry plate to reflector, as follows:

Hand and wrist	5 to 10	seconds,	at 5 inches.
Forearm	10 to 15	"	at 5 "
Arm above elbow	½ to 1	minute,	at 7 "
Shoulder	10 to 15	"	at 10 "
Thorax	15 to 30	"	at 10 "
Hip joint	30 to 45	"	at 12 to 15 in.
Stones in kidneys	30 to 45	"	at 12 to 15 in.
Glass, iron, lead, etc., in any part of trunk (on an average)	30	"	at 12 to 15 in.

We have very carefully investigated every claim to quicker exposures than these, often by a personal visit, sometimes by correspondence with personal friends whose reliability was undoubted. We have been unable to learn of any results equally good having been obtained in shorter times by any one at any place with any form of apparatus, and we do not believe any such have been obtained. We except one or two cases of undoubted authenticity when wonderfully short exposures were secured; but the operator has, in these cases, not been able to secure such results a second time.

Manipulation—Development of the Plate.—Suitable and well constructed apparatus is not the only essential to good results. A great deal depends upon the operator and comparatively trivial differences in procedure make all the difference between success and failure. We describe here the method which we follow and which allows us to count with certainty upon securing at least nine successful plates for every ten exposures.

(a) General Adjustment.—First see that the coil is working smoothly and so as to give a uniform discharge in the primary. The secondary spark points should be separated by the distance given by the makers as proper for the tube. The coil must then be adjusted either by changing the e. m. f. at the primary or by variation of the vibrator adjusting springs so as just not to spark over this air gap. The tube should then be joined in parallel with this secondary spark gap. The coil may then be started up, using the fluoroscope to show whether direction of discharge is right. If not, the primary current should be reversed. If X-rays are not now profuse, the secondary discharge points should be further separated and the vibrator springs tightened so as to produce correspondingly greater discharge. Continue this until either X-rays are secured as desired, or the tube becomes too hot, or possibly blueish or pink in color. Blue denotes too low a vacuum to expect X-rays, but often a gentle running of the tube for ten or fifteen minutes while in this condition will raise the vacuum to a suitable value. Pink denotes a very low vacuum and usually means, in a tube which has ever been right, a puncture or leak; such a tube can only be made good by re-exhaustion and repair. With most tubes a vivid green fluorescence is the sign of the X-ray vacuum. With the Bowdoin tubes, as also with many others, the most efficient condition is with the platinum reflector plate at cherry red heat over an area of half or two-thirds that of the little finger nail.

Sometimes the vacuum will be too high for the production of X-rays with any length of secondary discharge. It may be reduced by gentle warming of the tube by a spirit lamp flame. Some reverse of the current in the tube, but this is apt to blacken.

Sticking of the vibrator must be guarded against; it is often fatal to the tube. This is because of the much larger current through the primary when such sticking occurs. Upon release, therefore, a secondary discharge much above normal is produced and this the parallel spark gap is unable to carry off. The tube therefore receives much more energy than it should and may break down even though the parallel spark gap be as advised by the manufacturers.

(b) The Plate and Its Development.—We have used at one time and another a number of different makes of plates with very fair success. For some time past we have confined ourselves to the Carbutt X-ray plates and though we are not prepared to say that they are the best plates to use, the results are so uniformly good as to make it seem inadvisable to us to try other plates not radically different in principle.

For developer we use the Carbutt "J. C. Tabloids"—three J and three C to five ounces of water; add about two drachms of restrainer (the usual 10 per cent. solution). Dr. Stern, of the Philadelphia Polyclinic, advises heating this developer until quite warm to the touch just before using. This we have found so good that we have adopted it as part of our procedure.

From 15 to 20 minutes will be required for development. The image will come up very slowly and not very sharply. Not much detail will be visible by holding up to the light. Continue development until the film outlines have similarly appeared and faded away to a general blackness upon the glass side. Then rinse and hypo.

The fixing generally requires from a half hour to two or three hours. This long time is probably partly due to the unusual thickness of the Carbutt X-ray films, but probably even more to some chemical condition set up by the unusually large quantities of restrainer used. Mr. Carbutt advises three J and three C tabloids to six ounces of water to 20 to 30 drops restrainer. Our experience is that a plate so developed always requires intensification; a tedious nuisance which can never give so good results as a normally exposed and developed plate.

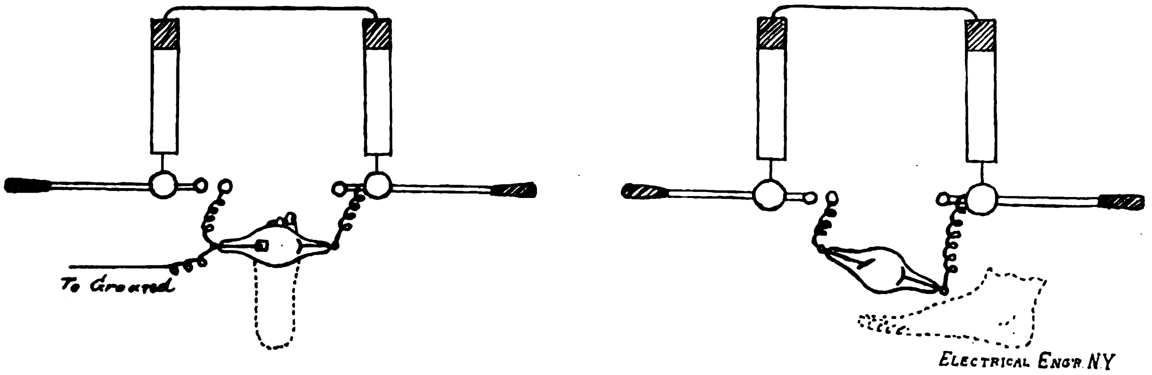
ELECTRIC TRAIN BULLETIN COMPANY.—Articles of incorporation have been filed at Camden, N. J., by the Electric Train Bulletin Company. The objects of the corporation are to manufacture, buy, sell and lease train bulletins or indicators and general devices. The capital stock of the company is $500,000, and the amount paid in is $1,000. The resident corporator is J. W. Harner, of Beverly, N. J.

X-RAYS OR STATIC DISCHARGE?

BY G. A. FREI.

IN the issue of The Electrical Engineer of January 6, Prof. Elihu Thomson expresses some doubts as to the correctness of my experiments published in the Engineer of December 23, 1896, and evidently thinks that the apparatus used were mere toys. Without giving a description of the apparatus which would be in the light of an advertisement, I will simply state that they were powerful enough to show the palpitations of the heart clearly and distinctly and cannot therefore be considered as toys.

The enclosed dagram, Fig. 1, shows the manner in which the experiments were made. It will be seen that the anode is grounded, an arrangement which enables one to use tubes having a comparatively high vacuum. Although the experiments were made during the first two weeks in November, the skin showed not the slightest discoloration or any other signs of the experiments when I wrote the article about the middle of December.



FIGS. 1 AND 2.—THE FREI EXPERIMENTS.

On December 21, I decided to try another experiment. The diagram, Fig. 2, shows the position of the tube and the connections. The result has been rather a surprise and of such a nature that I am obliged to modify my former views regarding the results obtained with the static machine. Neither Prof. Thomson's injury to his finger nor the effects of my last experiment, however, can change my views regarding the cause of the effect. The injury is evidently caused by an electric discharge from the wires or the ends of the tube, and if the necessary precautions are taken to carry this discharge to the ground the patient subjected to the X-rays will be perfectly safe.

Whether the same arrangement would answer the purpose when coils are used I am not prepared to say.

THE X-RAY PHENOMENA AND THEIR USEFUL APPLICATION.[1]

BY C. D. HASKINS.

AFTER describing the principal phenomena of the X-rays the author showed the different directions in which the X-ray has up to the present time proved to be of the most practical use. Already no inconsiderable number of lives have been saved by the speedy locating of bullets and the like, but it is not alone in surgery, that the X-ray phenomena find a useful field. In medicine, also, successful application of them has been made, especially in locating tuberculosis colonies in the lung tissues. The lung tissues when in their normal condition are probably more transparent to the X-rays than is other flesh, whilst fortunately, for the sake of consumptives, tuberculosis spots are relatively opaque. One can, therefore, readily detect with the fluoroscope and still more readily by photographic means, little dark spots in the lung tissues which indicate the presence of these bacteria.

In the arts the X-ray phenomena will pobably speedily be put to many useful applications. In the inspection of gems, alone, the X-ray is very useful. Diamonds, for example, are practically transparent to the X-ray, while all known forms of paste are quite opaque. It is, therefore, but the work of an instant to detect by means of a fluoroscope the falsity of even the best imitations; and this same holds true with a large number of the other precious stones.

Possibly, also, successful rough analyses of coals may be accomplished by means of the fluoroscope. The density of the shadow of a coal sample, viewed through the fluoroscope, is dependent upon the percentage of ash, and by matching the shadow of the sample under investigation with that of a sample of coal of similar size and thickness, and with a known percentage of ash, speedy and probably quite accurate results may be obtained.

In the inspection of all classes of small merchandise the X-ray apparatus will probably some day come into general use. Objects of all kinds, when composed partly of metal, or other relatively impervious substance, and partly of some relatively permeable material, can be examined with the greatest certainty. There is no difficulty, for example, in determining just how deeply a screw-driver is set into its handle, or just how long the fastening screws or nails are in a box. So, too, parcels, or mail packages, can be examined quite successfully without being opened. Mr. Haskins suggested that possibly this hint would not be misplaced if gently communicated to the United States Custom House.

Mr. Haskins illustrated his remarks by numerous lantern slides.

POWER TRANSMISSION

THREE-PHASE POWER PLANT IN THE BOLT WORKS OF PLUMB, BURDICT & BERNARD, NORTH TONAWANDA, N. Y.

ALTHOUGH the transmission of power outside the limits of Niagara Falls is not yet a month old, a large nut and bolt works at North Tonawanda, has been waiting, fully equipped for the appearance of the current, for the past year. These works, the largest nut and bolt factory in the country are those of Messrs. Plumb, Burdict & Bernard.

At the time the electrical equipment was under consideration, the question of utilizing Niagara power naturally arose, and it speaks volumes for the foresight both of the owners of the works and the equipping company, the General Electric Company, that the three-phase system was selected, instead of the two-phase. The three-phase system having been chosen by the Niagara Falls Power Company for the transmission of power from Niagara Falls to Tonawanda and Buffalo, the bolt and nut works can be operated directly from the transmission line by simply connecting the necessary static transformers.

The factory of Messrs. Plumb, Burdict & Bernard is situated at North Tonawanda, directly on the lines of the New York Central and Erie Railroads, and about half a mile from the route taken by the overhead wires of the Niagara-Buffalo transmission. It is divided into three single story brick shops, running north and south, the forge being nearest the railroad, the cold shop, engine room and machine shop, lying in the center and the threading and finishing shops on the side nearest the transmission line.

Until Niagara power can be obtained, the works are being operated from their own generating station, which will be abandoned as soon as the Niagara Power Company is ready to tap the three-phase lines into the factory. The generating station, Fig. 1, is set between the cold and machine shops in the central building. Steam from the engine is supplied by three Riter Brothers return tubular boilers, each of 100 horse-power capacity. The engine is an improved Green of 400 horse-power, belted to a General Electric Company three-phase, six-pole 150 kilowatt 25-cycle 500 r. p. m. generator. The exciter is a 3 kilowatt 125 volt bipolar machine. The switchboard is of the panel type, built up of two panels, one for the generator, the other for the feeders.

---

[1] Abstract of a paper read before the Northwest Elec. Assoc.

The forge shop, where the nuts and bolts are cut off from the raw rods and bars, is about 360 feet long, having the forges and machines set down each side of a central aisle, along which a track is laid. Above the machines on each side runs a line of shafting, and in arranging the line of shafting Messrs. Plumb, Burdict & Bernard have adopted a very simple method. Suspended from the roof girders down each side are four lines of channel iron in two sets, each set bolted back to back. Each line is separated from the other about 20 inches. Through the space between each pair of channels, pass long bolts which support the hangers for the shafting, and allow of a ready rearrangement at any time. This method is adopted throughout the shop.

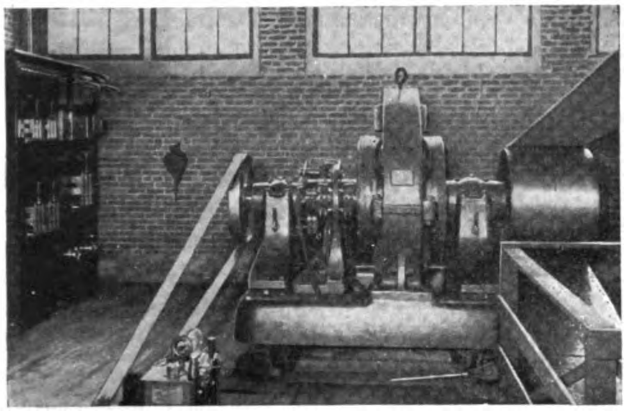


FIG. 1.—THREE-PHASE CENTRAL STATION, NORTH TONAWANDA NUT AND BOLT WORKS.

The forge shop contains five 20 horse-power General Electric induction motors, four driving the shaft and one operating a blower. The shafting is divided into four sections, and each one is belted to one of the induction motors. The driving motors themselves are set upon a platform above the shafting in the center of the shop, and are boxed in. The blower motor directly connected to the blower occupies a platform at the south end of the shop. The machinery driven by the motors in the forge shop are different sizes of bolt headers and nut punchers and shearing machines for shearing the bolt lengths from the rod.

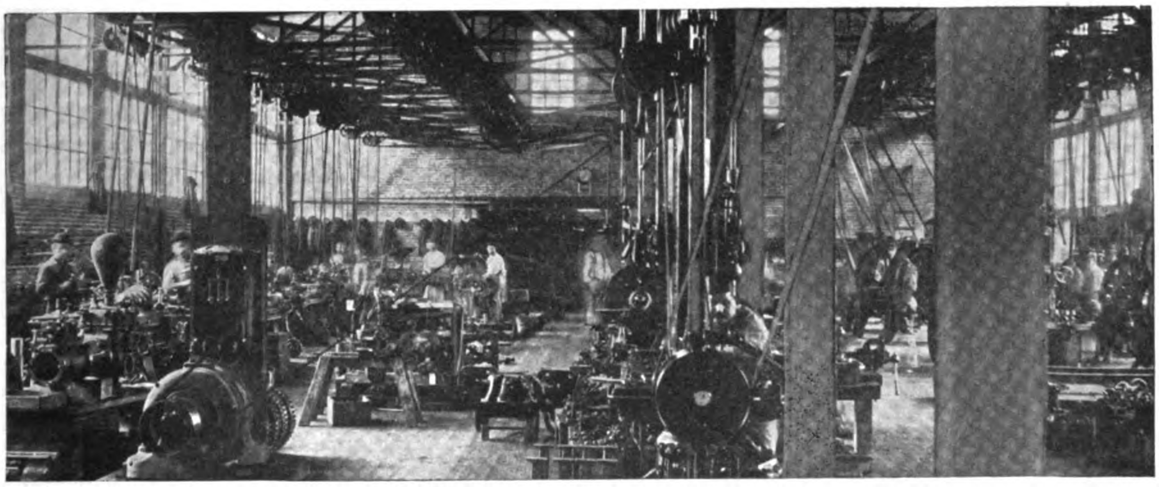

FIG. 2.—20 H. P. INDUCTION MOTOR DRIVING TOOL MAKING AND OTHER MACHINERY, NORTH TONAWANDA NUT AND BOLT WORKS.

In the cold shop the pointing department is operated by one 20 horse-power motor, set on the floor and belted to jack shafts and countershafts as necessary. In the machine shop, lying on the south side of the engine room, is another 20 horse-power motor, also set upon the floor. It is used to drive a variety of tool-making machinery such as planers, milling machines, drills, slotters, shapers, etc., Fig. 2.

The threading and finishing shop, 400 feet long, is next in length to the cold shop which is 430 ft. in length. In it the bolts and nuts traveling from the other shops are threaded and tapped and put together ready for the market. This shop is driven by six 6 horse-power motors set on small platforms, and three 20 horse-power motors. The smaller motors and one 20 horse-power motor is used to drive the automatic and semi-automatic machines. For the former they are belted to jack shafts from which belts are dropped to pulleys on a shaft running underneath the machinery. For the semi-automatic machinery, the pulley is on the level of the machines and is belted to the jack shaft above.

The other 20 horse-power motors are set on the floor and are belted to shafting on the opposite sides of the shop as shown in the illustration. These serve to drive the heavy threading and tapping work not automatic, and some idea of the variety of machinery in these shops, and the work the motors are called upon to do, may be gathered from the fact that the sizes of bolts made run from 3-16 inch up to 1½ inches.

The advantages of electric drive are markedly noticeable in this plant. There are no separate engines for the individual shops and no belt holes in the walls as would have been the case had the steam driving plant been confined to an outside building. The wires come through three small porcelain bushed holes in the wall of each shop. The central steam and generating station is confined to one room at present, and will probably shortly be entirely abolished. The motors in the forge shop occupy no space on the floor of the shop and those in the other shops occupy either small space upon the floor or are erected on small platforms. They require no attention beyond the filling of oil wells, which is performed but once in six months. They are started by the throwing of a switch, and maintain a steady and constant speed under all conditions of load. This is noticeable in the quality of the output.

LITERATURE

NOTE BOOK OF TABLES, DIAGRAMS, AND USEFUL INFORMATION. Ziegler & Co., Boston. 51 pages, 5 by 7 inches. Paper cover. Price, 30 cents. This is a handy little booklet containing much useful information, such as tables of resistances, dimensions, etc., of copper wires, wiring tables, etc., It also includes a number of diagrams for wiring motors, bell circuits, burglar alarm circuits, and telephone circuits both for two sets and for intercommunicating systems of various kinds. It ought to prove very useful in the hands of amateurs as well as professionals.

GLASGOW is about to establish an elaborate system of electrically-regulated municipal clocks. Between 200 and 300 clocks with 18-inch dials are to be placed in prominent positions throughout the city.

Vol. XXIII. NEW YORK, FEBRUARY 3, 1897. No. 457.

OCEAN DEPTHS.

THE discussion on the Pacific cable and the movements on both sides of the Atlantic indicate the nearness of the approach that is being made to the execution of the enterprise. It has semed to many people that there has been an inordinate amount of preliminary talk, stretching through a weary number of years; but the cabling of the other, lesser oceans was not accomplished without the lapse of a prolonged period of necessary work and agitation. Important as these cables are and profitable as most of them turn out to be in the long run, when well managed, it takes no little time to overcome the indifference of governments or capitalists, or to harmonize the various interests. In the case of the Pacific cable there was until recently some doubt as to its earning capacity. The rapid development of political changes in the Far East, with concurrent commercial advances, have shown at once that a cable there ought to be and that it would pay. At this moment, that point is pretty well settled, unless, as happens occasionally, the eagerness for the prize should lead the contestants to overdo the thing; thus laying two cables where one will at first amply suffice. Next, however, to the question of earning a profit, and perhaps even more immediately interesting is the problem of laying the cable successfully.

It is well understood that the Pacific Ocean offers many serious difficulties; their nature and variety have often been alluded to in these pages. Chief among them, of course, are the extreme lengths between landing places and the enormous depths. None but those who traverse the Pacific realize its magnitude, but a study of any map shows how scattered are the destinations any one of which should serve as the terminal in the antipodean orient. With regard to depth, it is interesting to bear in mind the fact that while a depth of about 5¼ miles has been found in the Atlantic, that recorded in the Pacific is about 6 miles; and that one of the deepest Atlantic cables lies in some 3 miles of water. The importance of this comes in when dealing with a cable route like that of the Pacific which is a good round 7,000 nautical miles, while an Atlantic cable is one-third that length. Moreover, the Pacific bed appears susceptible to a noteworthy degree to submarine volcanic disturbances, tending to destroy or modify a cable bed suitable for other reasons. It is said that the deep water in the Pacific is much colder than that in the Atlantic, but this would obviously lend itself to better conductivity and cleaner signaling, while on the other hand, the enormous depth to which it may be necessary to descend, with consequent increase of pressure, may have its influence on the type of cable adapted to withstand the strain.

MR. TESLA'S VIEWS ON THE FUTURE OF ELECTRICITY.

THE inauguration of the Buffalo-Niagara electric transmission, brought together, as our report showed, a representative gathering of influential men and elicited a number of memorable addresses. Of the speeches devoted to the technical side, that of Mr. Tesla's deserves more than passing notice, as containing the expression of his latest views and convictions on subjects which he has made his special study for some time past. Speaking of the types of prime movers in use to-day, Mr. Tesla gives no encouragement for the future of the reciprocating high speed engine in its present form, nor for the steam turbine. His ideal engine is one which expands the working fluid with utmost rapidity and loses little heat in the walls; an engine stripped of all usual regulating mechanism, packings, oilers and other appendages and forming part of an electric generator. Mr. Tesla, though not mentioning it by name, here evidently referred to his oscillator, brought out in 1893. As to the outlook for a carbon consuming battery. Mr. Tesla does not consider it over-promising, viewed from the standpoint of a source of power. The probability of replacing the engine-dynamos by batteries is, in Mr. Tesla's opinion, a remote one, the more so as the high pressure steam engine and the gas engine give promise of a considerably more economical conversion. Mr. Tesla also sees drawbacks lurking in the fact that carbon to be consumed in batteries has to be prepared for that purpose and cannot be used as found, as it is under the boiler. The manipulation, cleaning, renewal, regulation, etc., of the batteries, and their size, together with the character of the liquids employed in them, would make it difficult, if not unprofitable, to handle such a plant in a densely populated city district. While thus expressing little faith in the carbon battery, Mr. Tesla has hopes for the ultimate supply of isolated plants or dwellings in the development of what he calls a light "storage battery," involving the use of chemicals manufactured by cheap water power, such as some carbide or oxy-hydrogen cell. We incline to the opinion that what Mr. Tesla has in mind partakes more of the nature of a primary gas battery.

But it is Mr. Tesla's conclusions on the results of his own particular work which will perhaps command the greatest attention among electrical engineers and the public at large. It will be recalled that in his very first lecture at Columbia University in 1891 he threw out the suggestion that it might be possible to operate engines at any point on the earth "by the energy of the medium." Six years of continued study have brought him beyond the stage of mere conviction, and he now feels sure that the realization of his ideas is not far off. But at the same time Mr. Tesla confesses the disappointing conclusion reached by him that under the theoretically best conditions such a method of obtaining power cannot equal in economy, simplicity and many other features the present method of converting the energy of falling water into electric current, and transmitting it over long distances at high potential. With this conviction of the greater utility of water power, Mr. Tesla has bent his energies to the means of transmitting it, and now informs us that he has devised means which permit of power transmission at potentials much higher than are now considered practical. He hints further that the progress he has made gives him fresh hope that he will be able to transmit power from station to station without the employment of connecting wires, but he adds that, whatever method of transmission be ultimately adopted, nearness to the source of power will remain an important advantage. We cannot help expressing our gratification at this promised realization of one of Mr. Tesla's fondest dreams, but we hardly expect that the manufacturers of wire will receive the announcement in a like spirit of joy. Mr. Tesla has thrown out enough in his remarks to put the public again on the qui vive. The electrical community will await with impatience the practical demonstration of his new methods, accept the "report of progress" and "extend the time of the committee."

ELECTRICAL FARMING.

STATISTICS show that the value of the agricultural and live stock products of the United States for exceeds in value the worth of its manufactured articles, but strange to say, in probably no industry do we find electricity less applied than on the farms. And yet just in this direction lies what, we are convinced, will be one of the broadest applications for electric energy for all purposes. Farming operations are now carried on very generally by machinery, in the tilling of the field, in the preparation of the farm products for market, and again in its consumption on the farm itself. What could be more desirable, therefore, than the carrying on of all this work by electric power, which has the great advantage that it can be readily and cheaply brought to the exact spot where it is wanted? Just what can be done in this respect is well brought out in a recent United States Consular Report which describes the electrical installation on a farm in Mecklenburg, Germany. The power is originally obtained from a small brook, the water of which drives a turbine of about 16 horse-power, connected to a continuous current dynamo. The plant is also provided with a storage battery, so that it is enabled to store the energy of the waterfall during the time when the farm machinery is not in operation. Conductors lead to all points of the farm, driving motors for thrashing, sawing logs, straw cutting, pumping and small machine tools, the farthest motor being 1,800 feet from the dynamo. The plant is run at about 140 volts.

This installation during the year furnished 34,000 horse-power hours of energy, including 120,000 lamp hours of lighting. The cost of the plant was $12,376, of which the electrical part figured at $7,140. The working expenses, including interest and depreciation, amounted last year to $1,428. The former working expenses were $1,713.60. This shows a difference of $285.60 in favor of electricity. But in addition to this there is gained the advantage that four horses can be dispensed with and the remaining horses are always ready for use—a matter of considerable importance at harvest time and other busy periods in the fields. Besides, the fact that power is always available enables the farmer to employ his hands at once in thrashing, in case they are prevented by bad weather or by some other reason, from working in the fields. Of course the difference in working cost above indicated appears small in itself, but when it is considered that the whole plant is capable of developing only 16 horse-power at the turbine, of which considerable was lost in transmission, owing to the low tension adopted, the showing is a good one. Besides the æsthetic value of the installation, which affords electric light for all the buildings, including all the animal houses, must also be considered, though it may be hard to estimate. We are not unmindful of the fact also that in the case under consideration the power was derived at the low cost, delivered, of about 4 1-5 cents per horse-power hour, due to the cheapness of the water power, and that available water powers are not a universal adjunct of farm lands. But the interurban electric railway and the enterprising central station in farming districts are gradually reaching out for the farm. Only recently we described a farm motor installation in Pennsylvania operated by single phase alternating current at a distance of nearly five miles from the central station, with the most gratifying results. Just at present much attention is being given to the adapting of electric motors to machine tools, an innovation at first pooh-poohed by machine tool builders, but which they are now all gradually being forced to adopt. We might suggest that the manufacturers of agricultural machinery could, more than any one else, hasten the day of the supremacy of electricity on the farm, by adapting the electric motor to the apparatus they build. Instead of the portable steam engine plant dragged about to every point where work has to be done, with the frequent boiler explosions due to low water power, electricity will be available at all points from wires connected to a small central power plant. This is no fancy picture, and those who may devote their attention early to this work will be well rewarded for their enterprise. We have here only had in mind the application of electric power to farming work, but there is also much of interest and value attaching to the application of electricity direct to the soil, and of the electric light in the cultivation of plants; but these things may well be left until the more immediate work can be got into shape and put well under way.

HIGH VOLTAGE DISTRIBUTION.

AN article by Mr. H. Scholey in the February issue of "Cassier's Magazine" does what is but tardy justice to Mr. S. Z. de Ferranti, and we are glad to see the work and merit of that wonderfully able inventor and engineer presented with such clearness and sympathetic treatment. The article is, indeed, very well written and very interesting. The main facts in Mr. Ferranti's career are not unfamiliar to electrical engineers in this country, but few of us here appreciate how much he has done. It is enough to remember his early insistence on his ability to transmit alternating current at 10,000 volts from Deptford, and to note that 140,000 lamps in London now depend on the Deptford plant and circuits that he set up for that "impossible potential." That he is still a pioneer is seen in his latest alternator supplied to the Deptford station, a machine of 2,000 horse-power, which Mr. Scholey says is probably the largest in Europe, and which gives a current of 120 amperes at 10,000 volts, having also been run up to 12,500 volts. It runs at a peripheral speed of 11,000 feet per minute. With such an example before them, why should not the builders of the next big dynamos for Niagara put the high voltage right into the machines, and dispense with the step-up transformers whether for two-phase or three-phase work?

IF there is a rare thing in this world it is zig-zag lightning, and the artists therefore when they paint the phenomenon always make the zig-zag flash across their pictures as zig-zag as possible. It is said that to the English artist Turner, who made so wonderful a study of all atmospheric effects, was the first to paint lightning in the curvilinear, wavy form that photographs now reveal it to have. The magazines have had one or two articles recently, in which lightning pictures are shown, made from photographs, and in every one the flash looks quite curly. In no instance is it like a steep flight of stairs to heaven. This should help reconcile the artists who count more on the way the thing looks than the way the thing actually is; and many of whom are still unreconciled to the poses and attitudes of Mr. Frederic Remington's realistic horses.

THE Gas Exhibition at the Madison Square Garden is extensive and interesting, but we fear it can hardly be justifying the hopes of its promoters. In fact, it might perhaps be taken as the "swan song" of gas, for the public betrays little concern or curiosity and even the technical public has not betrayed a very lively interest. We are sorry for this, as the management has been enterprising, and there are many objects worthy of study and attention. But the fact remains that gas in this instance, contrary to its nature, has not been recognized as expansive in its possibilities by the great show-going and curiosity-loving population of New York.

ELECTRIC TRANSPORTATION

TROLLEY TRIUMPHANT IN CONNECTICUT.

A SPECIAL dispatch from New Haven, Conn., says: Notwithstanding the measure introduced in the State Senate to repeal what is known as the "parallel clause" of the general street railroad law, the leaders of the trolley interests in the State Legislature say that they are seeking no general legislation in their own interest, and, to use their own words, are "asking for nothing" and are contented with the situation as it stands. It remains true, however, that the existing "parallel clause," which imposes on the Superior Court Judges a decision as to whether a projected trolley parallel is a public necessity and convenience, will be opposed by many of the projectors and promoters of new trolleys. It is not generally known that the "parallel clause" applies to a projected new trolley road intended to parallel an existing trolley line as well as to a new trolley road intended to parallel a steam road. This partly accounts for the fact that a good many of the operating trolley companies favor the existing clause, the repeal of which is, therefore, doubtful, notwithstanding the trolley interests in combination undoubtedly control at this time both houses of the State Legislature.

What use they will make of their strength is now a question which arouses more interest throughout the State than any other matter before the Legislature. The common opinion seems to be that the trolley interests will at least so far work together as to help any of the trolley schemes which are resisted by no other interest except the New Haven Railroad Company. The hostility of the trolley corporations to that company, which has so long and bitterly fought them, and which crushed so many trolley enterprises in the Legislature of 1893, is well defined, and that very many parallels of the steam lines, will be authorized seems certain. One feature of the new situation is the rise in price of the bonds of trolley roads in this city, especially of the older roads. But it is believed that not half of the new trolley roads which will be chartered by the Legislature as a result of the steam railroad defeat will ever be built.

New Haven Railroad officials, in explaining their defeat, attribute it chiefly to the craze for trolley roads in many of the towns around them, which are seeking quicker transit. That craze, however, is not more marked than it was two years ago or four years ago, and the chief reason alleged for the steam railroad defeat are the anger of the lobby agents whose bills were cut down by the New Haven Company after the last session, and the better organization before election of the trolley corporations, which in many towns applied the "trolley test" to legislative candidates.

Surveys have begun for a new trolley road between Bristol and Meriden via Southington, a distance of about ten miles It will be a short "cut off" between the New England and New Haven steam lines.

EXTENSION OF ELECTRIC RAILROADING IN IRELAND.

United States Consul Ashby writes from Dublin as follows: The Dublin United Tramways have published notices of their intention to proceed in Parliament, session of 1897, with bills to permit extensive construction of new lines and to substitute electric traction for horse-power upon the existing lines. The company have also given notice of their intention to proceed before the privy council, Easter sittings, 1897, for authority to extend, vary, and enlarge existing tramway lines with such changes at passing places or crossings as may be necessary. All of these notices are the legal preliminaries toward the adoption of electricity as the means of traction upon existing lines and such new extensions as they may make. The new extensions contemplate a large number of lines connecting the various suburban districts with each other and with the city proper. The Dublin, Wicklow, and Wexford Railway Company have also given notice of their intention to proceed in the parliamentary session of 1897 with bills to allow extensions of their system of railways and with power to substitute electricity as the motive power upon their system to such extent as they may choose. This company now operates about 140 miles of railway. It is said that it is the intention of the company to substitute at an early date electric traction for both passenger and goods trains on their line from Westland Row (Dublin) to Bray, a distance of about 14 miles, most of the way lying through populous suburban towns. It is alleged that the competition of the Southern District Electrical Tramway, which parallels this line for 8 miles, has made this change necessary, as this line, which was opened in May, has already seriously interfered with the earnings of the railway and is constantly growing in favor with the suburban population. The municipal council of Bray is also favorably considering the construction of an electric tramway. Bray is a fashionable seaside resort, with a constant population of about 10,000, and has at present no tramway system. I also understand that the Tramways Company of Belfast intend to apply to Parliament for power to substitute electric traction on the tramways of that city. Should the action of Parliament be favorable to these various projects, there should be a good Irish demand for electrical goods.

AN ELECTRIC FREIGHT LINE.

Surveys are being made for the line of a proposed twenty-eight-mile electric railroad, which is to connect Norway with North Waterford, Stoneham, Harrison, and Bridgeton, Me. The road is to be used mainly for freight, and standard steam railway cars equipped with electric motors are to be used. For the passenger service, cars with express, smoking, and baggage compartments are proposed.

MECHANICAL

MEETING OF HEATING AND VENTILATING ENGINEERS.

THE annual meeting of the American Society of Heating and Ventilating Engineers was held last week at the house of the American Society of Mechanical Engineers. A number of interesting papers were read having more or less bearing on work which the electrical engineer is frequently called on to take into consideration. Among them were the following: "Methods of Proportioning Direct Radiation," by Prof. R. C. Carpenter; "Determining the Volume of Air Passing through a Register per Minute," by J. H. Kinealy; "Arrangement of Mains in Hot Water Heating Apparatus," by W. M. MacKay; "Circulation of Steam for Heating Purposes at or Below the Pressure of the Atmosphere," by R. P. Bolton.

Prof. R. C. Carpenter also read a paper on the "Relative Efficiency of Ventilation by Chimney and by a Fan." After stating the laws of the operation in each case the author gives a table showing the number of times that a fan or blower is more efficient than a chimney in discharging air from the top, with the outside temperature at 60 degs. F.

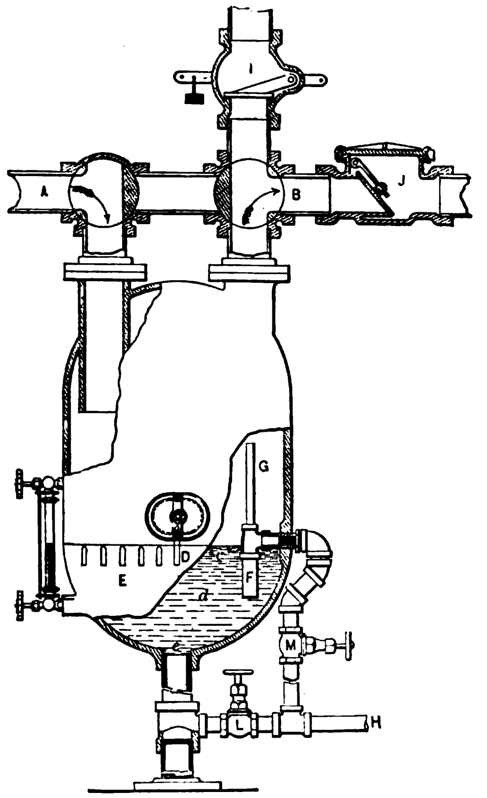
The table shows that in delivering air from a chimney 100 feet in height, even when the exhaust steam is wasted, the poorest fan will do nearly three times as much ventilating and the best 12 times as much as a chimney for the condition when both are using the same amount of heat. When the exhaust steam is utilized the average fan will move more than 100 times as much air as a chimney with the consumption of the same coal.

A fan is seldom used to draw air from a passage or flue, but is often used to deliver air into a passage or flue, and as this air is seldom heated the work of a fan under usual conditions is more fairly compared with the second case in chimney ventilation, viz., that of delivering cold air into a chimney.

A table embodying the latter conditions has been calculated by Prof. Carpenter, assuming that the exhaust steam is not utilized. This table includes a range of chimney heights from 10 to 300 feet and of chimney temperature from 80 to 450 degs. The table shows that with a 100-foot chimney and with the chimney gases at 400 deg., a fan or blower is 17.3 times as efficient as a chimney under such conditions.

Mr. W. J. Baldwin presented a very interesting paper on "Separation of Oil and Grease from Exhaust Steam," in the course of which he described a grease extractor devised by himself, which had given excellent results in practice. The author employs oil dams within the bulb, shown at E in the illustration, the upper edges of which dams are slightly above the water level of the apparatus, and their depth about three inches, with a high dam at D to prevent the return of the oil over the surface of the grating formed by the low dams E.

It was found in practice that with this arrangement the surface of the water at E was depressed and that the general movement was towards the high dam D under the lower edge of which both oil and water passed, the oil accumulating at C and the water returning in an under current again at the lower level just under the edge of D to fill up the space between the grating formed by the dams E E. This water is thus kept continually clean and ready to receive each deposit of grease, and it has been found by actual practice that the lighter oils are condensed by the contact with the water, so that the processes within the separator are akin to what one may call "washing the steam."



THE BALDWIN GREASE SEPARATOR.

The illustration shows the entire arrangement of the grease separator. Steam enters at A through a three-way cock, is cleansed of its oil and passes out again through B, either through the check valve J to the heating apparatus, or through the back pressure valve I to the roof. The accumulated water within the body of the apparatus is carried away through the overflow F, which is made non-syphonable by the open pipe G, allowing nothing but the excess of clean water to pass to the blow-off tank sewer.

Occasionally the valve L is opened and the dirt, water, and oil blown out. The gradual overflow of clean water from F prevents the clogging of pipes or sewers which would be the case by the constant dripping of oil.

THE OPPOSITION TO MR. H. C. PAYNE.

President Keelyn, of the Western Telephone Construction Company, has organized a remarkably strong opposition to the appointment of Mr. Henry C. Payne as Postmaster General. The protest recently referred to in these pages has been forwarded to Mr. McKinley, with the signatures of about 175 persons, most or nearly all of whom appear to be actively identified with opposition telephone interests. The chief ground of objection urged against Mr. Payne is that he is a "Bell benchman."

A PROGRESSIVE SHOP GIRL.

Anne Weiser, who in her capacity as shop girl was interviewed recently, as to what she would do if she had the new million dollar house of Mr. J. D. Rockefeller, among other sensible things, said: "I would have electric lights and furnaces and there would be real comfortable rooms lighted and heated for the servants."

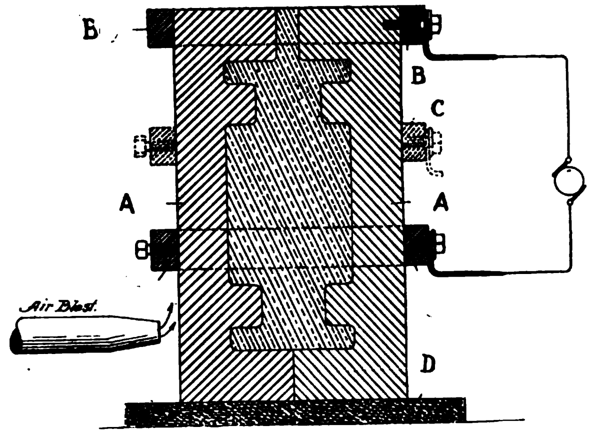
MISCELLANEOUS

ELECTRICITY IN ALUMINUM CASTING.

It has been found that with such metals as aluminum, where the shrinkage is considerable and special precautions have to be taken to overcome it, the most satisfactory results are obtained by heating the mold to the temperature of the molten metal when cast, that is, the molds should be heated to about 1,200 degrees Fahrenheit, which is about the temperature of molten aluminum. Then the ingot mold and metal contained therein are cooled together by special process, as by a blast of cold air or water, until the metal in the sinking-head or "riser" of the casting is the only portion still retaining its heat.

This system is the one which has been found to be the most satisfactory in the manufacture of aluminum bicycles; in fact, it is the only method which has been found to be satisfactory for making difficult castings as the frame work of bicycles.

A process having the same object in view, but allowing of more certain results being attained has just been patented by Capt. Alfred E. Hunt, of the Pittsburg Reduction Company. In this method, instead of the heat being applied externally, the heating is done by passing an electric current through the metal mold, and taking off the current at the desired times and as wanted, thereby more conveniently and accurately obtaining the desired temperature of the mold in the cooling of the aluminum and similar metal castings.



HUNT'S METHOD FOR CASTING ALUMINUM.

The accompanying engraving shows the manner in which the method is applied in practice. The mold is supplied with two contact rings, the upper one, B, being fixed and the lower one, A, movable. Current is first sent through the contact rings until the mold is heated up to the temperature of molten aluminum. The metal is then poured and the lower contact ring A moved upward towards B, as shown in outline at C, so as to shorten the circuit through the mold and molten metal and to cause the upper part to be heated by the current while the heating influence is removed from the lower part. The lower part will then cool, and its cooling is accelerated by water or an air-blast. The contacts are then approached still more, so as to expose more of the lower part of the mold to the more rapid cooling, and so the operation is continued until the casting becomes solid and sufficiently cold to prevent unequal shrinking. As the chilling of the metal progresses slowly from the bottom to the top, the casting shrinks in like direction and sound castings are produced. The whole operation is economical and very efficient, especially when it is conducted in places where electrical energy is cheap.

JACKSONVILLE, FLA.—The work of laying the extension of the Jacksonville Street Railroad is being rapidly pushed ahead. The road bed is being graded, and all work is being done as the work progresses. About 1,500 feet of track will be laid.

CONVENTIONAL DIAGRAMS OF ELECTRICAL APPARATUS.[1]

BY D. W. C. TANNER.

IT has become apparent, more especially in the last few years, that the use of simple and comprehensive diagrams is necessary in order quickly and conveniently to represent the different forms of electrical apparatus and their innumerable arrangements.

Perhaps the most noteworthy of the efforts which have been made toward uniformity of symbols has been that of Prof. Francis B. Crocker, whose chart appeared in The Electrical Engineer of May 13, 1891, and was afterward reprinted in Houston's "Electrical Dictionary." This chart was compiled for the use of students at Columbia University. While many of the diagrams are in common use to-day, there are some which have become almost obsolete in so short a time as six years, and many totally new ones are required which have become necessary since the chart was published.

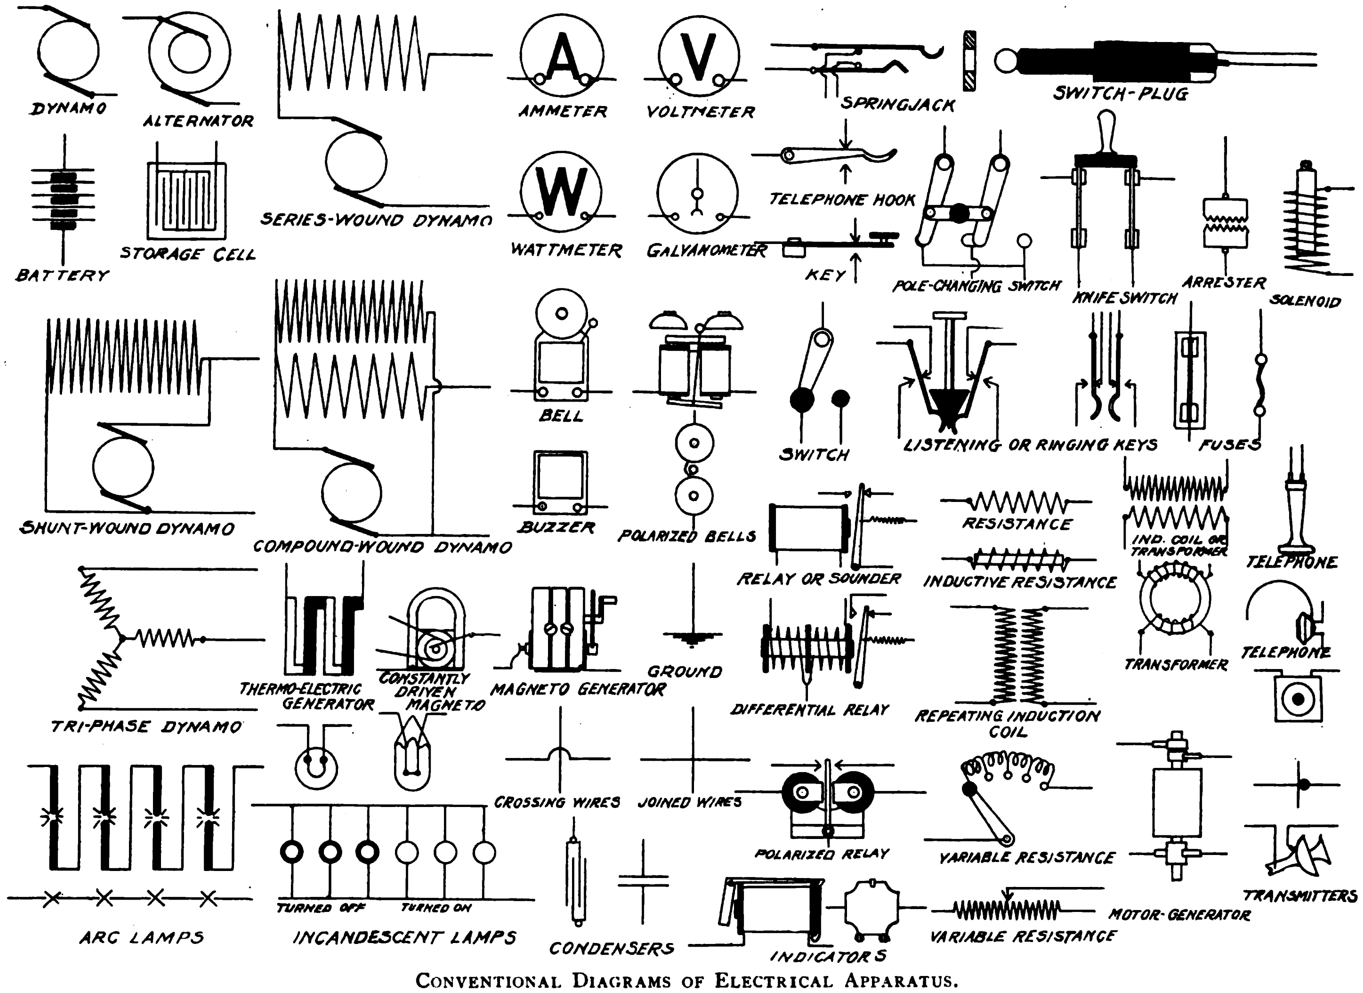
In 1873 C. H. Davis and F. B. Rae published a "Handbook of Electric Diagrams," which deserves but a passing notice, for the work was designed merely to show the circuits and mode of operation of a number of telegraph instruments, and not their simple representation.

The Patent Office has done something toward simplification and uniformity, but by criticism rather than by definite instruction. If the diagram submitted does not please the examiner, it is promptly rejected, but often without giving the applicant a very clear idea of just what is wanted. The most that is done is to refer to the work of some attorney whose diagrams are considered good.

Prior to 1892, the method of illustrating a telephone exchange system varied pretty largely with the tastes of the individual. Very often a switchboard was shown in vertical section, complete, with the keys, spring jacks, plugs, etc., in their proper places, fully drawn in detail. About this time Mr. F. R. McBerty, of the Western Electric Company, began the work of simplification, and the present method of illustration, which is remarkably clear and easily understood, is very largely the result of his work.

The symbols shown in the accompanying chart have been selected as being those which, upon careful comparison with others, seemed to be the best adapted for the purpose. Of course, it is very difficult to make such a chart complete, but it is hoped that the majority of the symbols for which demand is most frequent, will be found without difficulty.

Where more than one symbol is shown for the same device, the simpler form is intended to be used where it is desired to show a number of the devices, and that which bears a somewhat closer resemblance to the original will be best adapted where only one or two are required. The intention was not to show the circuits and mode of operation of complex systems or mechanisms, but only to indicate the symbols for the elemental or unit pieces or apparatus, which may be combined at pleasure.



CONVENTIONAL DIAGRAMS OF ELECTRICAL APPARATUS.

ALUMINUM FOR ELECTRICAL CONDUCTORS.

BY C. C. BURR.

IN substituting aluminum for copper for conveying current from the power house of the Niagara Falls Hydraulic Power and Manufacturing Company, to their pot room building, the Pittsburg Reduction Company made this innovation because aluminum had many qualities in common with copper and others in addition that made it particularly desirable. The relative location of the power house and pot room rendered the installation of the line exceedingly difficult, as the power house is situated at the bottom of the Niagara gorge, nearly 250 feet below the building where the current is used. This line being vertical and of sufficient cross section to carry at least 10,000 amperes, and owing to its considerable length of rather large cross section relative to the amount of current transmitted, rendered it exceedingly difficult to install.

To construct a line of this length and carrying capacity requires nearly 24 tons of copper, while if made of aluminum its weight would be only 11½ tons, with the same current capacity as the copper line. Furthermore, aluminum, owing to its lightness, is no more expensive than copper, is equal in strength, and superior, in that it is not so easily corroded. Another advantage gained through the lightness of aluminum was the saving in the construction of the wire tower. This tower is a steel-frame structure fastened to the side of the penstock and follows the general course of it from the power house to the top of the gorge. This wire tower would have necessarily been heavier had copper been used.

---

[1] Abstract of a paper read before the Chicago Electrical Association.

Considering all the merits of the two metals, the Pittsburg Reduction Company adopted aluminum in place of copper, as it had advantages over copper to more than offset its lower conductivity. The relative conductivity of copper and aluminum is as 100 is to 63; but as copper is 3.3 times heavier than aluminum weight for weight aluminum has a conductivity relative to copper as 208 is to 200. The temperature co-efficient of the two metals is nearly the same.

The details of the line are as follows: Each conductor is made up of 250 ⅜-inch rods, 350 feet long. This seems at first to be a somewhat complicated construction, but it possessed many advantages over the ordinary form of conductor for this particular location. The rods in this conductor being in one piece at once dispenses with all intermediate joints and splices. These rods are supported in the wire tower at intervals of 25 feet. The supports are of wood and the conductors are so fastened that each rod is supported independently of the others. This method of support affords an easy means of equalizing the weight, and providing for expansion and contraction by changes of temperature. This is accomplished by making an S-shaped bend in each rod just above each support.

It may be of interest to note that in addition to these conductors that carry the current up the side of the gorge, the current used in reducing aluminum is distributed to the pots or furnaces through aluminum conductors. These conductors have the same area as the main cables, but are made up of flat bars instead of round rods. In this connection it may be stated that these bars are subjected to particularly severe use as they are exposed to considerable heat and to acid fumes. Notwithstanding this, these conductors do not corrode sufficiently to cause any trouble, or show any tendency to warp out of shape.

Aluminum has been in use for electrical conductors in both the upper and lower works of the Pittsburg Reduction Company for some time, and has shown itself in no way inferior to copper and it is perfectly safe to say, I think, that it has passed the experimental stage and has shown itself as an electrical conductor, as in other uses, the equal of copper.

THE FIN DE SIECLE SAFE BURGLAR.

BY SLEUTH.

A NEW and very perfect illustration of the fact with which all electrical experimenters are familiar—the difference between laboratory experiment and practical use of electrical manipulation—has just recently come to the surface; which, originating in the columns of a daily newspaper—you know how profoundly scientific and eminently practical a daily reporter is—has been copied, profusely lengthened, made as terrible and ghostly as possible, by some of the electrical journals, and has sent shudders of fear through the brains and bodies of bankers and other unfortunates who have money under time locks and other safeguards, who dislike to part with their valuables without proper consideration.

Alas! for their future wellbeing. There is no safety in the coming years for their hoarded wealth, if this newpaper prophesy is to be credited. Now, we are told, it has become possible for the expert electrical burglar to use a current of 350 to 500 amperes, at a pressure of 40 to 50 volts, and go through an iron safe wall of three to six inches in thickness, in from three to ten minutes. This has been done—in the laboratory. Previous to perfect success in this line, however, it will be necessary the burglar should procure his supply of current, at the proper voltage; or, arrange so that, by having his amperes in one vessel and his volts in another, they can be mixed according to his needs. Kept apart in that way the fiery element could do no harm.

He cannot be quite sure of proportions in ordinary commercial currents, and, consequently, he might possibly err fatally in picking up the wrong conductor.

But, in addition to all that, before he can reach the safe, he must cross a perfect network of wires, so placed out of sight as to defy inspection, positive and negative in the same flexible cord, to cut which means a short circuit; burglar alarms on every gate, door, window, and in certain floor boards; connected to chairs, desks, stools, etc., the disarranging of any one of which rings the alarm. Having passed all these barriers successfully, if he ever could, when he attacks the safe, long before he can melt his way through the outer layer of metal he has brought two wires together, rung an alarm, without knowing it—and he doesn't get into the safe after all.

The original article on this sensational subject suggested that the supply of current could be readily taken from the street main. So it could, most certainly. In proof of this the fact has been repeatedly shown that men can, and have, taken the current from supply mains, even more than is required for melting through safes, though in numerous instances the parties maintained most perfect silence about it ever after.

I hardly think electrical safe burglary can be looked upon as an exact science up to date.

LETTERS TO THE EDITOR

DR. PERRINE AND THE CHICAGO SCHOOL.

MR. R. A. BAGNALL, of the Chicago School of Electricity, in his letter to you protesting against my disclaimer of connection with their school, states that this has not been announced except in so far as using my name as an editor of the Lesson Leaves they are publishing would imply such connection. He also states that no one interested financially in the National School of Electricity is in any way connected with the Chicago School of Electricity, but as I knew that it was publicly charged that the Chicago school was a direct outgrowth of the National school, I wrote to you in order that it might be clearly understood that I had no connection with this outgrowth.

I charged bad faith on the part of the managers of the National School of Electricity because although they originally agreed to publish the Lesson Leaves only as lecture syllabi for the information of their own students, these lesson leaves were published in book form and subsequently the copyright was sold, my name being used as one of the editors without my consent and without my having had any effective connection with their preparation as an editor. As I previously wrote you I reviewed these lessons as they were issued and after they were completed, protesting against certain matter which I found in them, but I was unable to see that my suggestions had any effect upon the true editors and at the time the National school failed I had already written a letter to the president protesting against the publication of these Leaves, but did not mail the letter on account of hearing that they had failed before it was possible for me to do so.

I do not now intend to criticise the Lesson Leaves either favorably or unfavorably, and simply state that I was in no true sense an editor of them, although I endeavored to act in that capacity as required.

Pardon me for encroaching on your space in this matter, but I have been charged with having written my previous letter without proper information, and I desire to have it known that my position is unchanged by any information received since its publication.

FREDERIC A. C. PERRINE.

January 22, 1897.

THE SIEMENS-HALSKE UNDERRUNNING TROLLEY.

WE have noticed from time to time both in the reading columns and advertising columns of your paper that statements were made by certain competitors that they absolutely owned and controlled the patents covering all underrunning trolleys.

This statement does not refer to the Siemens trolley or contact bar, the well-known device in use all over the world, which has been described repeatedly; it makes a sliding contact with the trolley wire, making overhead construction very simple and doing away with the necessity of switches and frogs, besides making it impossible for the device to be "off the trolley."

There were also statements in the papers that certain American companies had patents on electric railway conduits and had installed what they pleased to term "The Buda Pesth Conduit System."

It is a well-known fact that the first successful electric conduit system—the Buda Pesth conduit system—was installed by Messrs. Siemens & Halske, Berlin, and all United States patents covering the main features of this system are owned and controlled by the Siemens & Halske Electric Company of America.

The Siemens & Halske Electric Company are prepared to furnish complete trolley stands and trolley contacts and to install complete trolley stands and trolley contacts and to install complete electric conduit railway systems under the patents they own and control or they are willing to license prospective customers under these patents.

We think that these facts—and facts they are—will be undoubtedly of interest to many of your readers and we ask you kindly to mention them in the reading columns of your valuable paper.

F. B. BADT, Sec'y.
Siemens-Halske Electric Co.

Chicago, Ill., Jan. 28, 1897.

A NEW (?) METHOD OF SPEED CONTROL FOR ELECTRIC MOTORS.

In the December 16, 1896, issue of The Electrical Engineer there appears an article by Prof. W. A. Anthony, under the above title, propounding a scheme for the speed regulation of motors. This idea is brought out as new. As a matter of fact, it is very old. There is a patent to Wightman and to one other person in the United States; there is a patent to Rechniewsky in France, patents to Essberger in Germany, and, I believe, also an English patent, although I cannot give its name. Essberger's patent is No. 84,182, issued June 10, 1894. The patent to Rechniewsky is some years before this. I cannot give the exact date at the moment.

Machines embodying the idea in question have been built to a considerable extent by the Union Elektricitäts-Gesellschaft, of Berlin. Quite a number of machine tools were fitted with motors of this type and exhibited at the recent Berlin Industrial Exposition. A line of these motors is listed in the last general catalogue of the Union Elektricitäts-Gesellschaft, dated April, 1896.

It is strange that such an old idea should be brought out at this late date as apparently new, especially as so many patents have been taken out on the subject.

Professor Anthony's method of accounting for sparking in motors might be considered new. The sparking in a motor is not due to the disappearance of magnetic lines, but to their distortion into the region of commutation.

JOHN B. BLOOD.

Berlin, January 11, 1897.

(Mr. Blood has forwarded to us the catalogue referred to in his communication.—Eds. E. E.)

PERSONAL

CONOVER-GOE COMPANY.

THE gentlemen interested in this new company, just established at Chicago, bring to it years of experience in the electrical business. This, combined with ample capital to carry out their plans of work, would seem to promise a successful future. Although a "new company" in one sense of the term the members of it are by no means "new" to the central stations and consumers of the United States. As will be seen, the business to be carried on is in reality an amalgamation of the interests, in the Western States, of several different concerns under the management of Messrs. Conover and Goe. These lines of manufacturing have been successful for a number of years, but it is the purpose of the Conover-Goe Company to extend the field of operations and to increase the demand for the output of the various factories interested.

Mr. George W. Conover is well and favorably known to the electrical fraternity. He was for many years the buyer for the old Electrical Supply Company, and his associations with that company brought him into personal contact with the leading manufacturers of electrical and hardware specialties. The acquaintances thus formed have since been added to by several years of activity in selling electrical supplies. It is a rare thing to find the qualities of a good buyer and a good seller combined in one person, but Mr. Conover's business career seems to warrant the assumption that he has the two talents strongly developed.

GEORGE W. CONOVER.

D. E. GOE.

Mr. D. E. Goe has been identified with electrical development, as he expresses it, ever since he was 'knee high to a duck," having made an application for patent on sundry improvements, etc., when only thirteen years old. As he stands about six feet in his "stockings" we estimate his experience covers a period of about thirty years. His actual work began with the unpoetical occupation of scooping out telephone postholes under the direction of the late Wiley W. Smith. However, he soon determined to climb up, and various promotions brought him to the position of State Superintendent for the Southern Telephone and Telegraph Company. About this time electric lighting was claiming a large share of energetic talent, and Mr. Goe became engaged in the installation of isolated plants. The fund of practical experience gained in this occupation has been of invaluable service. In 1890 he made the acquaintance of Mr. F. S. Terry and was asked to assume the duties of advertising manager for the Electrical Supply Company. To this work he applied himself with a zeal that smacked of dormant newspaper acumen, and station men were taught through the advertising columns of the trade press that the Electrical Supply Company was by all odds the biggest thing on deck at that time, and they also discovered that there was a real funny, as well as a serious side to the station man's daily toil. For the last two years he has been manager for the Central Electric Company and has also directed the advertising work for them.

The Conover-Goe Company have contracted for the entire output of electrical and hardware specialties manufactured by the C. H. Dicke Tool Company. Other lines controlled in Western States are made by the Paragon Arc Lamp Company, Boston, Mass.; the line of Hartford switches made by the Gibbs Electric and Manufacturing Company, of Hartford, Conn.; porcelain specialties, rubber goods and insulated wire made by C. S. Knowles, Boston, Mass. We have no doubt that the affairs of the Conover-Goe Company will at once assume gratifying and profitable proportions and we are quite certain that the many friends of the gentlemen interested will wish them all possible success.

MR. C. B. STERLING has become president of the Standard Electric Lamp and Novelty Company, of 248 West Twenty-third street, New York City, taking the place of Mr. Chas. A. Fowler, who has resigned in order to devote his attention to other pressing interests. Mr. Sterling is a very young man, of energy, tact and experience, who is already well known and greatly liked in the industry. He informs us that his company has its hands full of business, and is supplying a good many new customers. The company will be glad to answer inquiries as to small lamps and novelties in the illuminating decorative line.

MR. MORRIS F. TYLER.—An unsuccessful attempt was made about a week ago to abduct the four-year-old son of Morris F. Tyler, president of the Southern New England Telephone Company, in New Haven. The little fellow was seized while playing on the lawn in front of the house and taken to Whalley avenue, where his screams attracted the attention of a bystander and the thief dropped the boy and ran. The boy, Leonard, was taken to his home and Mr. Tyler notified the police.

MR. H. C. DAVIS.—A gold watch was taken from the pocket of Henry C. Davis at the Grand Central station on Jan. 26. More than could be realized on it was offered in an advertisement for its return to the owner's son, C. H. Davis, No. 99 Cedar street. The watch was presented to Mr. Davis when he was president of the Electric Club. He is now president of the State Line and Sullivan Railroad, in Pennsylvania, and his home is in Philadelphia.

PROF. A. G. WEBSTER, of Clark University, is delivering a course of ten lectures at the Lowell Institute, Boston, on the nature of electricity and its relation to the various phenomena of the ether.

SUPT. J. ELLIOT SMITH, of the Fire Department, has been commended by Commissioner La Grange for the economical management of his department of telegraphs.

THE STOCK MARKET

ACTIVITY AND STRENGTH.

CONDITIONS improved again last week, the close of which found the market cheerful and even buoyant. The main reason was perhaps the activity and strength in all leading bonds, prices of which have materially advanced, while many are simply unobtainable.

Attention is being directed to the copper stocks, whose advance reflects a more active demand for the metal, due in no small measure to the revival of electrical uses. A year ago copper was at 10 cents, and in spite of very dull business in this country it advanced to 11½ cents at the close. That was an advance of 1½ cents. The year opened with copper at 11½ cents, and with any sort of good business, instead of the advance being 1½ cents it will be 3 cents for the year.

Electrical securities were firm and in brisker inquiry all the week. General Electric sold from 34⅛ up to 35⅞, and its more sanguine supporters predict an early 40. Twenty-one thousand seven hundred shares changed hands, or nearly five times as many as of Western Union, which remained quiet around 84. In Boston, American Bell declined ¼ to 212¾ on sales of only 367 shares. Other electrical stocks are quiet. The general commercial improvement is shown in the fact that the number of business failures fell off no less than 103 for the week, as compared with the preceding week, or about 25 per cent., a remarkable gain for the better also over 1896, by 67.

REPORTS OF COMPANIES

DISSOLUTION OF THE RIES ELECTRIC SPECAITY CO.

The affairs of the Ries Electric Specialty Company, of Baltimore, were finally wound up at a meeting of the directors last week at the office of Bernard Weisenfeld, who, with Mr. Sylvan Hayes Lauchheimer, were appointed receivers of the company in July, 1894.

The meeting was called to order by Mr. Elias E. Ries, the president of the company, and was attended by a majority of the directors and stockholders. The receivers submitted a statement showing that the account filed by them in Circuit Court No. 2 provided for the payment of all the merchandise creditors of the company in full, with interest to date. A resolution was then passed formally dissolving the corporation according to law.

The Ries Electric Specialty Company was incorporated in June, 1891, with a capital stock of $25,000, which was subsequently increased, in June, 1892, to $150,000.

EDISON ILL. CO. BROOKLYN, N. Y.

The Edison Company, of Brooklyn, at their annual meeting re-elected the old Board of Directors and officers. The report submitted contains a great deal of interesting matter, and among other items of interest it announces that during the year 16,098 feet of underground mains and 6,981 feet of underground feeders had been added. The overhead system of the Citizens' Company has 417 miles. The meter department has a total of 2,810 meters. At the foot of Sixty-sixth street, the company has arranged to place a large station, with the intention of equipping it so as to run with the utmost economy and efficiency, as well as for the transferring of current for any use economically to any part of the city. The condensed balance sheet shows: Debits—License account,$945,000; plant account, both companies, $4,120,628; insurance fund, $58,980; accounts receivable, $105,110; material and supplies, $54,943; cash on hand, $29,564; total, $5,314,227. Credits—Capital stock, $3,750,000; first mortgage bonds, $1,000,000; accounts payable, $72,085; bills payable, $155,000; dividend due January 15, $56,250; accrued interest, $12,500; insurance fund, $58,980; depreciation account, $150,000; profit and loss balance, $59,411; total, $5,314,227.

DEATHS FROM GAS IN BOSTON.

The many deaths in Boston by asphyxiation have directed sharp attention to the nature of the gas furnished, and it is likely that a legislative inquiry will result. Figures furnished by Dr. Draper for the district in which he is the medical examiner show twenty-four accidental deaths by asphyxiation in 1896. This is considerably over a third of the total number of such deaths in the district for eighteen years, while the first month of 1897 furnishes many more evidences of the peril. The increase in mortality is claimed to be coincident with the use of water gas. This latter is much more insidious than the old kind. There was a chance of resuscitation in cases of partial asphyxiation by coal gas, but the water gas poisons the system in a very brief time. Dr. E. S. Wood, of the Harvard Medical School, says that water gas contains as a rule about 40 to 50 per cent. of hydrogen, 30 to 40 per cent. of carbonic oxide, and about 10 per cent. of petroleum or naphtha gas. As it is comparatively devoid of odor, its escape from pipes and diffusion through the air of an inhabited room in dangerous amount cannot be readily detected. Carbonic oxide, Dr. Wood says, is one of the most active of poisons, producing, when inhaled, speedy death, and, according to Leblanc, one volume of it diffused through 100 volumes of air totally unfits it to sustain life. It is suggested by Dr. Wood that the addition to water gas of more petroleum gas would very greatly diminish the danger by imparting to the mixture a very powerful odor.

MR. CHARLES DICKERSON, until recently chief engineer of the Pabst Lighting and Heating plant, Milwaukee, has been chosen chief engineer of the Fond du Lac, Wis., Electric Company.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

BY MAX OSTERBERG.

Central Stations:

GRAPHICAL COMPARISON BETWEEN ALTERNATING VS. DIRECT CURRENT STATIONS. By Fritz Goldenzweig. Two stations built in Vienna in 1892 are carefully compared and results show considerable saving in the alternating current station over the direct.—Elektrot. Zeitschr., Dec. 31, '96.

Dynamos and Motors:

REPAIRS OF ELECTRICAL MACHINERY. By A. R. Harris. Author explains how simple repairs on armature or on connecting pieces may be made.—Am. Mach., Jan. 14, '97.

IMPROVEMENT IN CONTINUOUS CURRENT TRANSFORMERS. A diagram of a continuous current trasformer system of distribution for a district in which the power is so remote from the center of consumption as to make it undesirable to have direct supplementary low pressure feeders. Also an illustration of variable ratio transformers generating on one side 485 amperes between 205 and 240 volts the primary pressure being 1,000 volts.—Lond. Elec., Jan. 8, '97.

A TWO-PHASE ROTARY TRANSFORMER. The Alioth Electrical Company, of Munchenstein, has built a machine into which a two-phase current at 2,400 volts is fed, and then transformed down to 70 volts, into continuous current, to feed the three-wire lighting network.—Lond. Elec., Jan. 8, '97.

Electro-Chemistry:

RESISTANCE OF ELECTROLYTES TO ALTERNATING DISCHARGES. By Prof. Cardani. In the "Nuovo Cimento" for October, author states that electrolytes do not conduct such discharges through the surface layers, but evenly throughout their mass, that they obey Ohm's law, whatever the frequency of oscillation. Herein they differ from metallic conductors. Their impedance is equal to their resistance to continuous currents.—Note from Electricity, Jan. 20, '97.

THE PREPARATION OF MANGANESE IN THE ELECTRIC FURNACE. By Henri Moissan. With very large currents (500 amperes and 50 volts) the reduction of oxide of manganese can be accomplished in a few minutes.—Electricity, Jan. 20, '97.

Electro Therapeutics:

THE DEVELOPMENT OF THE HIGHER VOCAL REGISTER BY ELECTRICITY. By W. H. King, M. D. Paper read before the Nat. Soc. of Electro-Therapeutists. After an introduction dealing with the principles of physics, author compares the larynx to a musical box, the vocal register to a string under tension and shows how by electrically caused reactions the vocal chord can be made more flexible, thus being enabled to produce quicker vibrations, and hence develop higher vocal register.—Electricity, Jan. 20, 97, and subsequent issue.

Lighting:

DETERMINATION OF THE COST OF ELECTRIC LIGHTING BY GAS ENGINE. By J. L. Christy, M. E. and S. A. Hasbrouck, M. E. A test with 10 h. p. gas engine showed the cost of electric light from a dynamo connected by counter shaft to be for small loads .78 cent per lamp hour, while for larger loads this went down to .29 and .277 cent. The price of gas was figured at the rate of $1.25 per 1,000 cubic feet.—Stevens Indic., Jan., '97.

LIGHTING BY MUNICIPALITIES. By Frank B. Rae. Author quotes a number of specific cases in which cities saved considerable amounts after they had their own plants. While certain items such as taxes, water rent, etc., are lost as soon as the city takes the lighting upon itself, Mr. Rae believes that items such as depreciation should not be considered in the annual expenses.—Elec. Journ., Jan. 15, '97.

SOME NOTES ON THE USE OF HIGH VOLTAGE LAMPS. By G. L. Addenbrooke. Author admits that the progress in the manufacture of this type of lamps has been greater than formerly assumed by him; 220 volt lamps are being introduced in many places in England. But it is believed that 250 volt lamps will be the upper limit for some time to come. Lond. Elec. Eng'r., Jan. 1, '97.

RESULTS OF INCANDESCENT LAMP TESTS. By H. Riggert, Hanover. A large number of tables, showing efficiency, variations of voltage, etc.—Elektr. Zeitschr., Dec. 31, '96.

THE PROBLEM OF LAMP SUPPLY. By Dr. O. Gusinde. The city of Hanover's electricity works supply their customers with lamps free of charge under certain conditions; these are given in detail. The article also contains a copy of the forms in which specifications for bids are made.—Elektrot. Zeitschr., Dec. 24, '96.

ST. LOUIS LIGHTING CONTRACT. Detailed specifications issued by the Board of Public Improvements. The requirements are at present 7,000 arc lamps and 4,000 incandescents.—Elec. Journ., Jan. 15, '97.

ON THE EFFECT OF PRESSURE IN THE SURROUNDING GAS ON THE TEMPERATURE OF THE CRATER OF AN ELECTRIC ARC. By W. E. Wilson, F. R. S., and G. F. Fitzgerald, F. R. S. The greatest difficulty in the way of exact results seems to lie in the determination of the temperature of the crater. Editorially an interesting practical point in connection with this paper is brought out: If the temperature of the crater is lower than the vaporizing point, there is a possibility of the luminous efficiency of the arc being increased by some device which will raise its temperature nearer to the vaporizing point.—Lond. Elec., Jan. 8, '97.

Measurement:

THE METRIC SYSTEM IN ELECTRICAL INDUSTRIES. By F. S. Hickok. Paper read before the Chicago Elec. Assoc. Nov. 6, '96. Commencing with the methods and systems of the ancients, author gradually leads up to the development of methods of measurements up to the present time.—Electricity, Jan. 20, '97, and subsequent issues.

Miscellaneous:

TORONTO SCHOOL OF PRACTICAL SCIENCE. Illustrations and some particulars of the engineering equipment.—Can. Elec. News, Jan., '97.

ELECTRIC WELDING. By Sydney F. Walker. Paper read before the Bristol Channel Center of the Institute of Marine Engineers. After explaining that the term welding should really be applied to iron and steel only, author explains what the real process of rigidly combining two pieces of the same or of different materials is, and then takes up Thomson's, Terener's and Benardos' processes. Lond. Elec. Engr., Jan. 8, '97.

Power Transmission:

LOCAL DISTRIBUTION OF ELECTRIC POWER IN WORKSHOPS, Etc. By Ernest Kilburn Scott. The first of a series of articles commences with an enumeration of the advantages of electrical transmission of power to isolated points comparatively close together, such as the tools in a shop or factory. Author gives a table showing the relation between the power, total dead weight and number of bearings for different sized shaftings in several representative establishments.—Lond. Elec. Eng'r., Jan. 1, '97.

Railways:

THE SYSTEM OF THE WASHINGTON, ALEXANDRIA & MT. VERNON RAILWAY. This railway system consists of a combination underground conduit and high speed trolley. Descriptive details and illustrations of the important features are contained in Str. R'way Journ., Jan., '97.

STREET RAILWAY SYSTEM OF PARIS. Br. M. Lavalard. The first of a series of articles giving a general outline of the development of the railway system.—Str. R'way Journ., Jan., '97.

ELECTRIC RAILWAY POWER STATIONS IN AMERICA AND THE ECONOMIC RESULTS OF THEIR OPERATION. By L. D. Tandy. Author has prepared tables, the first one showing the type of station as to its first cost, boilers, pressure used, style of engines, method of general connections, cost of coal per net ton, pounds of coal per kilowatt hour, pounds of water per ton of coal, also per kilowatt hour; finally cost per kilowatt hour. The sum total for the latter varies from .0061 in the finest to .0112 in the poorest type of station. Another table gives percentage comparison between the high type stations.—Str. R'way Journ., Jan., '97.

ELECTRIC RAILWAYS WITH STATIONARY ACCUMULATORS. By Ludw. Schröder. Various methods used in actual practice are explained; of special interest is the plant in Meckenbeuren-Tettuang, where the storage battery is simply connected in multiple with the dynamos, which latter, however, though compound-wound, always run as shunt machines. In order to charge the batteries they are subdivided into several parallel sections, to cut down the voltage. Another interesting system is at Remscheid; there a booster is in series with a storage battery, the field of the booster being regulated by the main current, thus drawing the battery into use, or charging it or keeping it neutral.—Elektrot. Zeitschr., Dec. 31, '97.

MUNICIPAL CONTROL OF TRAMWAYS. By T. P. Wilmshurst. Author favors municipal ownership, principally for the reason that such roads are run with the intention of best serving the public, and that it is not even necessary for such a road to earn any money so long as it is self-sustaining.

In connection with municipal lighting plants, it offers the opportunity of straightening the load line.—Lightning, Jan. 7, '97.

Telephony, Telegraphy, etc:

NEW TELEPHONE EXCHANGE AT WINNIPEG. Some difficulty has in the past been experienced with boards, where it is necessary to transfer connections from one section to another, in having the line properly disconnected when the conversation was finished. A special feature has been introduced into this board to obviate the trouble.—Can. Elec. News.

Wires, Wiring, etc:

BARE COPPER MAINS. J. H. Tonge has had a stoneware conduit manufactured, which is cheap, easily and quickly laid. It is made in sections, two feet long, the ends being imbedded in concrete on stoneware bearers. In the course of manufacture a recess is cut out of every third section, within which an insulator, secured with pitch, is dropped. Copper strips are then laid in the slots of the insulators and the whole covered up with flagstones. The design permits of a feeder and three-wire distributor at a pressure of 440 volts between the outers.—Lightning, Jan. 7, '97.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JANUARY 12, 1897.

Alarms and Signals:—

SYSTEM FOR ELECTRIC SIGNALING. W. McC. Ramsey, Allegheny, Pa., 575,733. Filed Aug. 9, 1894.

Block signal system for a single track trolley road.

ELECTRICAL SIGNAL SYSTEM. P. Freeman, New York and R. B. Slater, Montrose, N. Y., 575,805. Filed May 25, 1896.

Means whereby a train may be prevented from entering upon a given block until the block is clear throughout its length.

SWITCH AND SIGNAL APPARATUS. J. G. Schreuder, Edgewood Park, Pa., 575,908. Filed Sept. 21, 1895.

Electropneumatic system.

Conductors, Conduits and Insulators:—

INSULATOR. F. Hoover, Paducah, Ky., 575,952. Filed May, 19, 1896.

Adapted to fit in the under side of the cross arms.

Dynamos and Motors:—

BRUSH-CARRIER FOR DYNAMO ELECTRIC MACHINES. S. S. Wheeler, New York, 575,918. Filed May 26, 1896.

Comprises rings insulated from each other and mounted on the frame of the machine at the inner end of the commutator, brush-carriers on the rings extending over the commutator, and brushes mounted on the carrier.

Electro-Metallurgy and Electric Smelting:—

ELECTRIC SMELTING. T. L. Willson, New York, 575,788. Filed February 20, 1895.

Consists in feeding the material to be reduced in a suitably pulverized condition, together with the reducing agent in similar condition, into an electric arc formed by alternating current.

ELECTRIC FURNACE. J. A. Deuther, Boston, Mass., 575,828. Filed August 21, 1896.

Comprises a suspended electrode, a mechanism for vibrating the electrode, and a feed mechanism for feeding the material to be treated within the path of the electric arc during the interval beween a back and forth movement of the electrode.

ELECTRIC FURNACE. J. Joyce and J. A. Deuther, Boston, Mass., 575,829. Filed October 12, 1896.

Similar to above.

Lamps and Appurtenances:—

WIRE GUARD FOR LAMPS. P. R. Wagor, Springfield, Mass., 575,794. Filed March 6, 1896.

Adjustable wire guard for incandescent lamps.

Measurement:

APPARATUS FOR DETERMINING ELECTRICAL RESISTANCES CONTAINING ELECTROMOTIVE FORCES. O. Frölich, Charlottenburg, Germany, 575,767. Filed May 11, 1895.

Employs a Wheatstone bridge system including the resistance in one of its lateral branches, means for causing variations in the current flowing through one of the diagonal branches of the bridge system, and means for measuring the ratio of the variations of the current in two diagonal branches.

ELECTRIC METER. W. C. Fish, Lynn, Mass., 575,777. Filed October 16, 1896.

Combines an armature, a field coil therefor, recording mechanism actuated by the armature, and means for weakening the field periodically.

Miscellaneous:—

ELECTROMECHANICAL MOVEMENT. E. D. Chaplin, Cambridge, and H. G. Halloran, Boston, Mass., 575,699. Filed March 21, 1896.

Reciprocating measurement adapted especially to rock-drills.

ROENTGEN RAY TUBE. E. Thomson, Swampscott, Mass., 575,772. Filed August 21, 1896.

Comprises a chamber having a Crookes vacuum and provided with a pair of concave electrodes both of which face upon a bombarded metal piece situated in substantially the focus of their concavities.

ELECTRIC APPLIANCE FOR HORSES. L. A. Gray, Arlington, Md., 576,053. Filed October 29, 1896.

ELECTRIC CONTROLLING APPARATUS FOR PNEUMATIC DESPATCH TUBES. E. A. Fordyce, Chicago, Ill., 575,883. Filed June 23, 1893.

Details of construction.

Railways and Appliances:—

RAIL SUPPORT. W. B. Potter, Schenectady, N. Y., 575,782. Filed August 25, 1896.

Rail insulator to "third-rail" system.

CLOSED CONDUIT ELECTRIC RAILWAY. E. W. Rice, Jr., Schenectady, N. Y., 575,785. Filed October 31, 1896.

Embodies an independent ground connection adjacent to the pick-up-magnet contact and adapted to protect the coils on the pick-up-magnets from leakage currents.

RAILROAD TRUCK. Alonzo C. Mather. Chicago, Ill., 575,723. Filed January 23, 1893.

An electric motor truck having the motor mounted on top of the truck and projecting into the car body above it.

GEARING FOR ELECTRIC CARS. Alonzo C. Mather, Chicago, Ill., 575,724. Filed December 1, 1893.

Similar to above.

TROLLEY TRACK FROG. W. J. Sumner, Holyoke, Mass., 575,770. Filed March 25, 1896.

Switches, Cut-Outs, Etc.:—

FUSE-HOLDER. W. W. Dean, St. Louis, Mo., 575,040. Filed September 19, 1896.

Consists of circuit terminals between which the fuse is adapted to be connected and a heavy grounding spring engaging one end of a lever forming one of the circuit terminals, the spring being adapted to effect the separation of terminals when the fuse is broken.

Telegraphs:—

PRINTING TELEGRAPH. O. L. Kleber, Pittsburg, Pa., 575,830. Filed July 18, 1895.

Details of construction.

Telephones:—

TELEPHONE TRANSMITTER. R. S. Barnum, Chicago, Ill., 575,869. Filed June 1, 1896.

Comprises a diaphragm and carbon block forming electrodes, the block being provided with a recess in its face adjacent to the diaphragm, a hinged tongue, and loose particles of conducting material arranged within the recess so as to partially cover the tongue.

MICROPHONE. P. Hardegen, Berlin, Germany, 575,887. Filed May 28, 1896.

Comprises a vibrating diaphragm, an electrode and a connection between the electrode and the diaphragm consisting of a flexible ring of material forming with the electrode and diaphragm a chamber for the granular material and serving to support the electrode on the plate to permit its vibration.

TELEPHONIC TRANSMITTER. M. Kotyra, London, Eng., 575,896. Filed November 17, 1896.

Comprises a vibratory helical case, carbon blocks at each end of the case, and granular microphonic material between the blocks.

LEGAL NOTES

CITY INJUNCTION AGAINST A PRIVATE PLANT IN PHILADELPHIA.

A Common Pleas court in Philadelphia has issued a special injunction in the suit of the city against C. J. Carney, restraining the latter from erecting, stringing or maintaining any poles or wires or other appliances for the purpose of supplying electric lights in the vicinity of Second and Marion streets.

The facts in the case are that, by ordinance of Councils, approved January 3, 1894, it is provided that "no telegraph, telephone or electric wires shall be erected over or across any of the streets, alleys or roads of the city of Philadelphia, without permission being first obtained from Councils by the passage of an ordinance to that effect, and no wires shall be strung until a permit is first obtained from the Department of Police and Fire Alarm Telegraph."

It is alleged that, in violation of this ordinance, the defendant is now, and has been for some time, conducting an electric light and power plant in the rear of the premises southwest corner of Second and Marion streets, and is engaged in supplying electric lights and power to a number of stores in the vicinity, and is maintaining electric wires over public streets and highways of the city without authority from Councils, or without having obtained permission from the Bureau of Police and Fire Alarm Telegraph.

SHAW vs. WORTHINGTON—AN ELECTRIC CRANE LITIGATION.

The case between Manning, Maxwell & Moore, representing the Shaw Electric Crane Co., and the Morgan Engineering Co., in the United States Circuit Court of New Jersey, known as the Shaw vs. Worthington case, has been decided in favor of the Morgan Engineering Co. Manning, Maxwell & Moore were represented by Francis Forbes and Frederick H. Betts, of New York City, and the Morgan Engineering Co. by John R. Bennett, of New York City.

This case has been a long drawn out patent litigation, covering years of time, and the Morgan Engineering Co. are being highly congratulated on their victory. The points in suit related to the use of motors for the various purposes of crane travel, hoisting and transverse motion.

THEFT OF CURRENT.

R. B. Mullen and Arvid Rydstrom, of the board of public works, Tacoma, Wash., have filed with the city clerk a recommendation to the city council that that body petition the State Legislature to pass an act to protect electric light currents. The communication says: "The unlawful taking of electric light currents has reached such a point that something must be done to have the matter put upon a better basis of protection."

TRADE NOTES & NOVELTIES

INTERIOR CONDIUT AND INSULATION CO.

The annual meeting of this company was held on Jan. 25, when the results of the business done in 1896 were shown to have been very satisfactory. Nothing of special public interest was brought before the stockholders. The following directors were elected: E. H. Johnson, H. Steers, A. C. Bakewell, C. D. Tows, Carl Schurz, J. Markle, J. C. Reiff, F. S. Hastings and F. H. Benedict.

FELTS.

ALFRED DOLGE & SON, 110 East Thirteenth street, New York, with factories at Dolgeville, N. Y., are supplying the electrical trade with wool felt used as a non-conductor between high potential transformer coils, also for storage batteries; felt wheels for polishing purposes, felt washers, etc. These felts are in quality surpassed by none on the market. Among the many that use them may be mentioned the Westinghouse Electric and Manufacturing Co., Pittsburgh, Pa.; Johnson Electric Service Co., Milwaukee, Wis.; General Electric Co., Schenectady, N. Y. "Dolge" felts are known all over the world, and Dolgeville is to-day a notable illustration of what is possible of accomplishment in America by any man with energy enough and courage to enable him to overcome the difficulties that inevitably arise in the pathway of progress. In 1875 Mr. Alfred Dolge, the founder of the firm of Alfred Dolge & Son, located a small felt factory at the place since named after him. At that time the place had but a few inhabitants, but it has since grown to a town of about 2,800 people, occupied largely in the manufacture of felts. Not alone are Messrs. Alfred Dolge & Son known for their superior goods, but they are also widely known for the co-operative system existing between them and their employés. They have "a just distribution of earnings system," established by Mr. Alfred Dolge, which includes a pension fund, by which after various terms of service the employés receive pensions ranging from 40 to 100 per cent. of their wages. A "labor insurance system" also exists, by which they are insured, at the firm's expense, for from $1,000 to $3,000 each, and an endowment plan by which the employés are credited each year with the difference between their "actual earnings" and the amount paid them in wages. Mr. Dolge laid out the streets, built houses, sewers, established an electric light plant, helped build a free school, and virtually founded and equipped the entire town of Dolgeville, N. Y.

ELECTRIC APPLIANCE CALENDAR.

The Electric Appliance Company have just completed the distribution of their calendar and moonlight schedule for 1897. It is a very large and elaborate affair, and the feature of a complete and accurate moonlight schedule makes it useful as well as ornamental. The Electric Appliance Company have tried to distribute these very generally to the Western trade, but if any have been overlooked, they will receive one of these valuable calendars on application to the Electric Appliance Company, 242 Madison street, Chicago.

PLATINUM.

Buyers in need of platinum can obtain it from Mr. C. F. Croselmire, 251-255 New Jersey R. R. avenue, Newark, N. J., in sheet or wire of any size or degree of hardness. Mr. Croselmire makes a specialty of preparing this metal in sizes required by the electrical trade, especially manufacturers of incandescent lamps. He also pays strict attention to remelting and exchange of scrap, etc.

ADVERTISERS' HINTS

THE BERLIN IRON BRIDGE CO., East Berlin, Conn., illustrate their regular pattern of double thickness corrugated iron shutter with the corrugations running at right angles to each other. These are built into a heavy angle iron frame, thoroughly supported by bonds, flanges, hinges, etc., and form a fireproof shutter under the most severe conditions.

THE STANDARD ELECTRIC LAMP AND NOVELTY CO., 248 West Twenty-third street, New York, will be glad to quote prices on minature incandescent lamps, Geissler and Crookes' tubes, and lamps for decorative purposes.

ALFRED DOLGE & SON, 110 East Thirteenth street, New York, advertise non-conducting wool felts for insulating felt wheels for polishing purposes.

PEERLESS RUBBER MFG. CO., 16 Warren street, New York, recommend the "Honest John" rainbow packings for water and hydraulics. They say there is nothing like it in the world.

J. HARPER BONNELL CO. express themselves entirely satisfied with the operation of an American-Ball engine furnished them by the American Engine Co., Bound Brook, N. J.

THE PURITAN ELECTRIC CO., New York and Boston, are able to make immediate shipments of their alternating current 100-hour arc lamp, but it is impossible to say how long they will be, if the present demand continues.

THE EXCELSIOR ELECTRIC CO. call attention to the "Churchward" multipolar apparatus manufactured by them, including direct connected generators for power and light; motors for direct connection to tools, elevators, etc.; belt-driven apparatus, starting boxes, controllers, equalizers, boosters, rotary transformers and motor dynamos. They are wound for any voltage with shunt, series or differential windings.

THE ELECTRIC STORAGE BATTERY CO., Philadelphia, Pa., claim the honor of installing in the largest and most modern isolated plant in the world, in the new Astor hotel, a battery of chloride accumulators of 4,000 ampere hours capacity.

STANDARD THERMOMETER AND ELECTRIC CO., Peabody, Mass., note the following advantages of the Upton alternating arc lamp: Burns on any frequency from 7,000 to 16,000 without change of adjustment; will not stick, overfeed or short circuit; made for either 10 or 14 amperes, as required.

THE STANDARD AIR-BRAKE CO., 100 Broadway, New York, have a word to say about their apparatus, and its adoption on high-speed trolley lines.

THE AMERICAN ELECTRIC HEATING CORP., offer "just the layout needed," as one of their customers writes, referring to their dealers' assortment of electric heating appliances sent with a show case for $25.67.

BRUNT & THOMPSON, East Liverpool, O., have brought out a regulating socket with many economical features.

K. McLENNAN & CO., Chicago, Ill., present additional testimonials to the merits of Gale's commutator compound.

THE WALKER CO., Cleveland, O., call attention to the construction of the armatures in their machines.

THE BIBBER-WHITE Co. are well stocked with full lines of hanger boards, adjustable binding posts, positive snap knife-blade contacts, switch cutouts and a complete assortment of general electric supplies.

MR. C. E. STUMP has taken hold of "City Government" as president, and is making it go with lots of swing and energy. The paper has a large field of usefulness, and Mr. Stump, as an old trade journalist, knows how to cover the ground. It would be hard to say what a municipality does not buy or do nowadays. The offices of the paper are in the American Tract Society Building, New York City.

MR. J. N. BAGGITT is installing a plant at Bartow, Fla., and will be there after February 10. He wishes to receive catalogues and prices of electrical machinery and supplies as soon as possible.

WESTERN NOTES

FUSE WIRE.—The Chicago Fuse Wire and Mfg. Co., 153 Lake street, Chicago, have just issued a very neat and new descriptive circular and price list of their well known tested fuse wire and links. It is fully illustrated and does this important subject justice. Mr. W. R. Goodman, the manager, has had eight years' experience in handling these goods, and knows fully the requirements of the trade. The company are now equipping their laboratory with the latest and best instruments, and are going to considerable expense in order that the tests may be thorough and that perfect goods may be placed on the market as "the standard for accuracy."

THE B. & O. ROAD has established a bureau of development, in charge of W. W. Peabody, Jr., and with H. A. Trondley as special agent with headquarters at Cincinnati. The object is to build up towns along the road where land and labor are not expensive, and where new factories can be advantageously located. The road runs through some excellent regions of this character.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, have made their excellent calendar for 1897 the medium of some effective advertising of the large number of electrical supplies for which they are the general Western agents. These include the Packard lamps, Packard transformers, "O. K" weather-proof wire, Paranite rubber covered wire, Armorite interior conduit, Upton arc lamps, "Electra" imported carbons, Whitney electrical instruments, Taunton bare copper wire, Boudreaux dynamo brushes, Dayton ceiling fans, Meston fan motors, etc. The lighting schedule is given with each day of the month during the year.

CENTRAL ELECTRIC COMPANY.—The big shipment of Wagner transformers described so graphically by Mr. Abadie last week was for the Central Electric Company, who supplied it to the National Board of Trade of Cycle Manufacturers at the Coliseum, Chicago, where it was duly installed by Mr. D. A. Kimbark. The shipment, installation and starting up were record-breakers for swiftness and satisfaction to the customer.

THE ARMORITE INTERIOR CONDUIT COMPANY, of Detroit, Mich., have secured the contract for the new Girard estate building, now in course of construction in Philadelphia. This building when completed will be one of the largest and most handsome buildings in that city, and about 200,000 feet of Armorite conduit will be required. Mr. James Fulton Cummings, the indefatigable manager of the Armorite Company, is to be congratulated upon this magnificent contract.

ST. LOUIS, MO. Mr. Chas. Green, president of the People's Railway Company, has offered to lease the cable conduit for wire subway purposes.

ST. LOUIS.—The St. Louis Electrical Supply Company are experiencing a strong demand for their celebrated St. Louis battery. Up to the first of the year they have booked orders for 20,000 batteries for '97 delivery. This certainly looks well for the prosperity of the coming year and incidentally would seem a strong indication of the superiority of the battery.

DENVER TELEPHONE.—The Colorado Automatic Telephone Company using the Strowger system is to set up in business in Denver. Doctors R. F. Le Mond and S. W. Jacobs are interested. They are also putting in a plant at Colorado Springs.

THE LANGUAGE PHONE COMPANY has been incorporated at Seattle, Wash., by W. H. Llewellyn, of New York, and W. C. Oakley, of Chicago, to be interested chiefly in phonographs. The capital stock is $500,000, divided into 5,000 shares of $100 each. The trustees of the company are: Oliver L. Spaulding, Chicago; Lee D. Matthews, Chicago; Edward A. Rogers, Chicago; Ellis Morrison, Seattle; Harry K. Allen, Chicago; Warren A. Drake, Chicago; Richard S. Rosenthal, Chicago; Franklin W. Jarvis, Chicago; and W. H. Llewellyn, New York. The principal place of business is Seattle.

MENOMINEE, MICH.—The Menominee Electrical & Mechanical Company have issued an illustrated circular on their combination bicycle lock and stand, which holds the wheel tire by a loop and a pair of jaws; each stand has its own special lock. The stand is very handy, and moderate in price, a good thing for stores and for individual riders.

THE ADVANCE ELECTRIC COMPANY, of Indianapolis, has been formed to deal in electrical supplies with a capital stock of $5,000. The directors are H. B. Marsh, D. B. Smith and C. H. Talmage.

THE PYLE ELECTRIC HEADLIGHT COMPANY to make headlights for locomotives has been formed at Indianapolis, with a capital stock of $25,000 by L. Hollweg, G. C. Pyle and F. H. Ewers.

NEW YORK NOTES

MR. W. S. HADAWAY, JR., of 107 Liberty street, New York, is to be credited with the designing and installing of the very ingenious electric heating apparatus placed by H. B. Coho & Co. in the Consolidated Dental Co.'s new factory, a description of which appeared recently in our pages.

FORD, BACON & DAVIS will hereafter be the name of the former firm of Ford & Bacon, the new member being Mr. G. H. Davis, M. E. They are moving into new quarters and after February 1 will be found in the St. Paul building, 220 Broadway, opposite the postoffice.

WHITMAN & COUCH.—In our advertising pages of last week, January 27, an error was made in the advertisement of Whitman & Couch. We inserted a description of the magneto ringing set of this company, but by an inadvertence the cut accompanying the description was of their wall set. The cut of the wall set is well shown, and the descriptive matter accompanying it, concerning their magneto ringing set, is properly set forth, but the two should not be taken in connection with each other.

WESTERN ELECTRIC COMPANY. C. L. W. Eidlitz, the architect, has planned an immense combination office and factory building for the Western Electric Company. When the structure is completed it will have a frontage of 145 feet on West street and 285 feet on Bethune street. It will be built of red brick and terra cotta and be ten stories high. At present, owing to an unexpired lease of the corner property, only the rear section is to be erected.

SILICA GRAPHITE PAINT.—The Joseph Dixon Crucible Company, Jersey City, N. J., have issued a couple of pamphlets in regard to this valuable article, which has proved so useful not only in preserving roofs of all kinds, but as applied to electrical poles and other structural work. One pamphlet is devoted to testimonials; the other contains a variety of other matter also, and something about the company.

THE CLONBROCK STEAM BOILER COMPANY, of Brooklyn, N. Y., have, they consider, proved the superiority of their Morrin Climax boiler over all the others, in securing the entire boiler contract for the Tennessee Centennial Exposition to be held the first of May next.

MR. GEO. T. DAVISON has resigned as superintendent of the electrical department of the Hackensack Gas and Electric Company, and will open an office of his own for supplying electrical outfits for private houses, offices and business plants.

MR. NEWTON L. SCHLOSS has removed his office to 39 Cortlandt street, New York, and would be pleased to hear in regard to any work requiring the services of a mechanical or electrical expert.

THE NEW COMMERCIAL CABLE BUILDING, to rear its lofty domes on Broad street, beautifies the New Year's card issued by the Commercial Cable Company.

THE DIRECT UNITED STATES CABLE COMPANY, LTD., have issued as usual a very neat and useful pad calendar mounted on a stiff cardboard, decoratively illuminated, and we are indebted to the New York manager, Mr. John Brown, for copies of it.

TRIPLETS.—H. B. Coho & Co., 203 Broadway, never do things by halves, and this year they issued to their friends no fewer than three sizes of 1897 calendars; so that you can take your choice. All three are neat, pretty and useful.

THE DE VEAU TELEPHONE TRANSMITTERS are a great success, and are efficient, it is said, chiefly because of the "coal grain" carbon used in them. This grain, however, is more in the nature of very fine shot-like balls. Hence there is an utter absence of packing, and a wonderfully fine transmission of sound.

THE STANDARD AIR BRAKE COMPANY, E. J. Wessels, general manager, 100 Broadway, has issued a very neat little record of its triumphs—for victories they certainly are—in introducing the air brake on street cars. But we must confess that this country does not yet show up in the proper proportion, in view of its greater use of mechanical traction. In this case, the heathen needing missionary work are at home.

NEW ENGLAND NOTES

IRON CLAD RHEOSTATS.—The Bibber-White Company, of Boston, among its other excellent specialties is handling the rheostats and theatre dimmers of the Iron Clad Rheostat Company, of Westfield, N. J. These products are in high reputation and brisk demand, and are to be encountered in a great many of the newer installations.

THE AMERICAN ELECTRIC HEATING CORPORATION of Boston have got out a complete revised price list in condensed form, completely describing their improved products. Many improvements have been made in the past year and new items added, while prices have been reduced. Dealers should get the new lists and new discounts.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., are putting up a new machine and blacksmith shop for the Robert Palmer & Son Shipbuilding Company, of Noank, Conn. The same company are furnishing a rolling mill for the Rome Brass and Copper Company, of Rome, N. Y., an iron roof for the new armory at Rutherford, N. J., and a new power house for the Plattsburg, N. Y., Light, Heat and Power Company.

THE UNITED ELECTRIC COMPANY, of Springfield, Mass., are about completing their new station at Indian Orchard and have placed an order with the Jewell Belting Company, of Hartford, Conn., for four 40-inch Jewell dynamo belts, each 70 feet long. This company in its different plants has thoroughly tested most of the more prominent makes of belting and have placed this order with the Jewell Company on account of the excellent records made by belts of their manufacture which have been in use a number of years.

PHILADELPHIA NOTES

MORTON & SMITH, engineers and contractors, Law Building, Baltimore, consisting of D. G. Morton and J. C. Smith, are doing considerable electrical work of a local character. Of late they have had several sub-contracts for the gun battery to be erected at Hawkins Point, Md.

READING, PA.—A charter has been granted to the Mansion Electric Co., of Reading, with $20,000, full paid in. The parties interested are: F. E. Bailey, of Philadelphia, president and general manager; Henry B. McCormick, secretary and treasurer; Vance C. McCormick, J. M. Cameron and L. U. Bailey, of Harrisburg. The plant has been started, and has a capacity of 2,000 lights, and was built by F. E. Bailey & Co., of Philadelphia.

BIRDSBORO, PA.—Application has been made for a charter by the Birdsboro Electric Co., by F. E. Bailey, of Philadelphia; George Brooke, George Brooke, Jr., Robert Brooke, Edward Brooke, of Birdsboro. Work has been started on the plant, it will be in operation by the 1st of June, and will have a capacity of 1,000 lights. F. E. Bailey & Co., Philadelphia, have the contract for the complete plant.

F. E. BAILEY & CO., Betz Building, Philadelphia, Pa., representatives of the Armington & Sims Engine Co., have the contract for building a complete electric light plant at Birdsboro, Pa., to have a capacity of 1,000 lights, to include a 100 h. p. engine. They have just completed a 2,000 light plant for the mansion Electric Co., of Reading Pa., that includes one 125 h. p. and two 40 h. p. engines, and have installed a 125 h. p. engine for the borough of Quakertown, Pa.; one 600 h. p. engine for the Nanticoke Light Co., of Nanticoke, Pa. The above engines are of the Armington & Sims new self-oiling type, with their new governor.

THE HESTONVILLE ROAD has made a fine showing in its recent annual report. The company now has 151 cars and carried nearly eleven million passengers in 1896. The total gross receipts were just short of $550,000.

THE SOLAR ELECTRIC COMPANY, of Brookville, Pa., has been formed with a capital stock of $10,000.

THE NEWTON MACHINE TOOL WORKS of Philadelphia report a very favorable outlook for future business. Among others, they report an order from The Central R. R. Company of South America for heavy milling machine equipment, including the heaviest class of rod milling machines, heavy plain milling machines, nut milling machines, vertical rotary planers, etc.

DOVER, N. J.—The Frick Company of Waynesboro, Pa., have recently furnished for the Dover Electric Light Company one complete 16x32x32 cross compound condensing Corliss engine, with steam and exhaust valves actuated by independent eccentrics; flywheel 20 feet diameter, 43-inch face; weight of wheel 40,000 pounds; made in segments. The shaft is 13 inches in diameter; the main bearings are 11 inches in diameter and 22 inches long; crank pins 6 inches long and 3⅝ inches diameter. The connecting rods are 3½ inches in the neck and 4⅞ in the center. The piston rods are 4⅝ inches and 2¾ in diameter, respectively, fitted with metallic packing. There is also a high pressure side with cylinder 16 inches by 42, with extended shaft; also wheel and main outboard pillow block arranged to receive the low pressure side in the future, so as to make the second cross compound engine, the same as that above named.

J. H. McEWEN MFG. CO., Ridgway, Pa.—The whole property of this company, including patents, good will, factory, machines in progress of construction, etc., will be sold at auction in Ridgway on February 22. No bid less than $100,000 will be considered.

SOUTHERN NOTES.

THE TRADESMAN ANNUAL.—The 18th annual number of the Tradesman, published at Chattanooga, Tenn., contains over 260 pages, and presents one of the most complete, exhaustive and valuable review of the South, its resources, development and possibilities, that to our knowledge has ever been published. The special articles are from the leading thinkers, statisticians and business men in our country; the information given is the result of careful investigation and practical knowledge. The business directories and statistics are most valuable features of this valuable number and it will be preserved as a reference book on all subjects pertaining to the South and its resources.

POWER TRANSMISSION

LOCAL DISTRIBUTION OF THE CATARACT POWER AT NIAGARA FALLS.

A GREAT deal of information has been given of late as to the long distance transmission of current from the Niagara Falls power plant to Buffalo, and the subject is necessarily one that excites general interest. But it is not to be forgotten that there is already a very large local distribution of energy around the power plant. Just what this is we are now able to indicate, for the first time, in a graphic way that will make the data an excellent supplement to the article by Mr. W. B. Rankine, which appeared in the New Year Anniversary Number of The Electrical Engineer. We show herewith the interior of the cable bridge across the canal, from the power house, Fig. 1, also the interior of the local subway, Fig. 2; and a map showing the location of the respective factories, which derive their power from the central plant, Fig. 3.

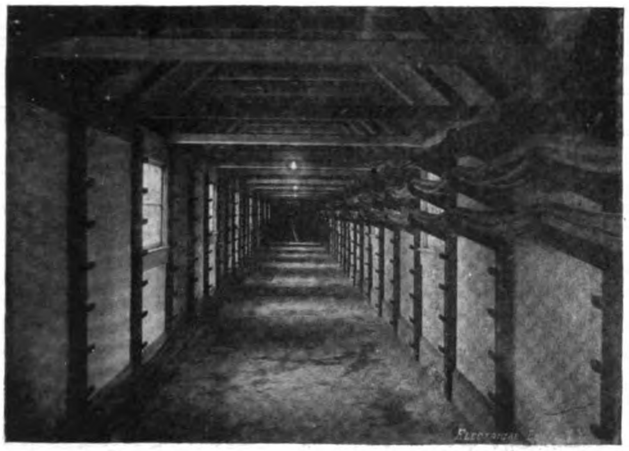

FIG. 1.—CABLES CROSSING CANAL BRIDGE, NIAGARA POWER PLANT.

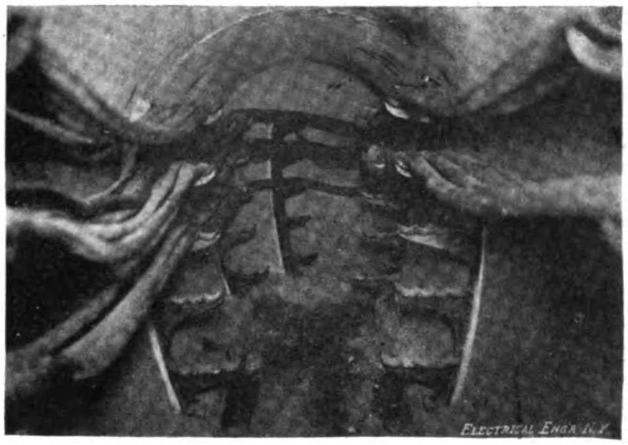

FIG. 2.—CABLES IN NIAGARA SUBWAY FOR LOCAL DISTRIBUTION.

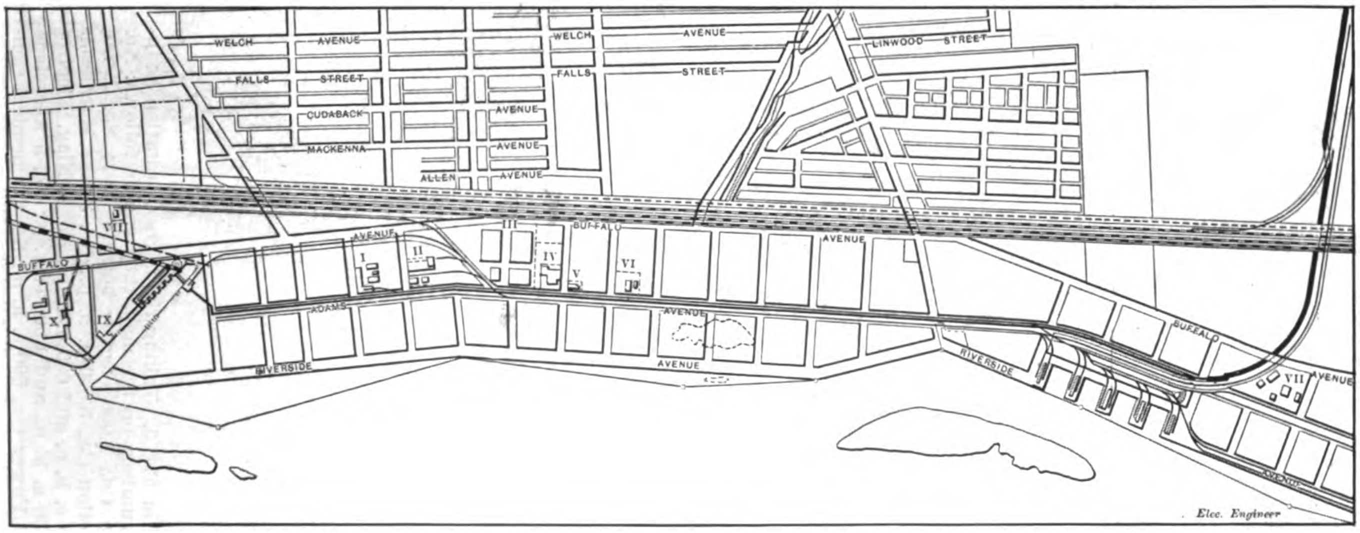

FIG. 3.—MAP SHOWING LOCATION OF FACTORIES USING NIAGARA POWER CO.'S POWER AT NIAGARA FALLS, N. Y.

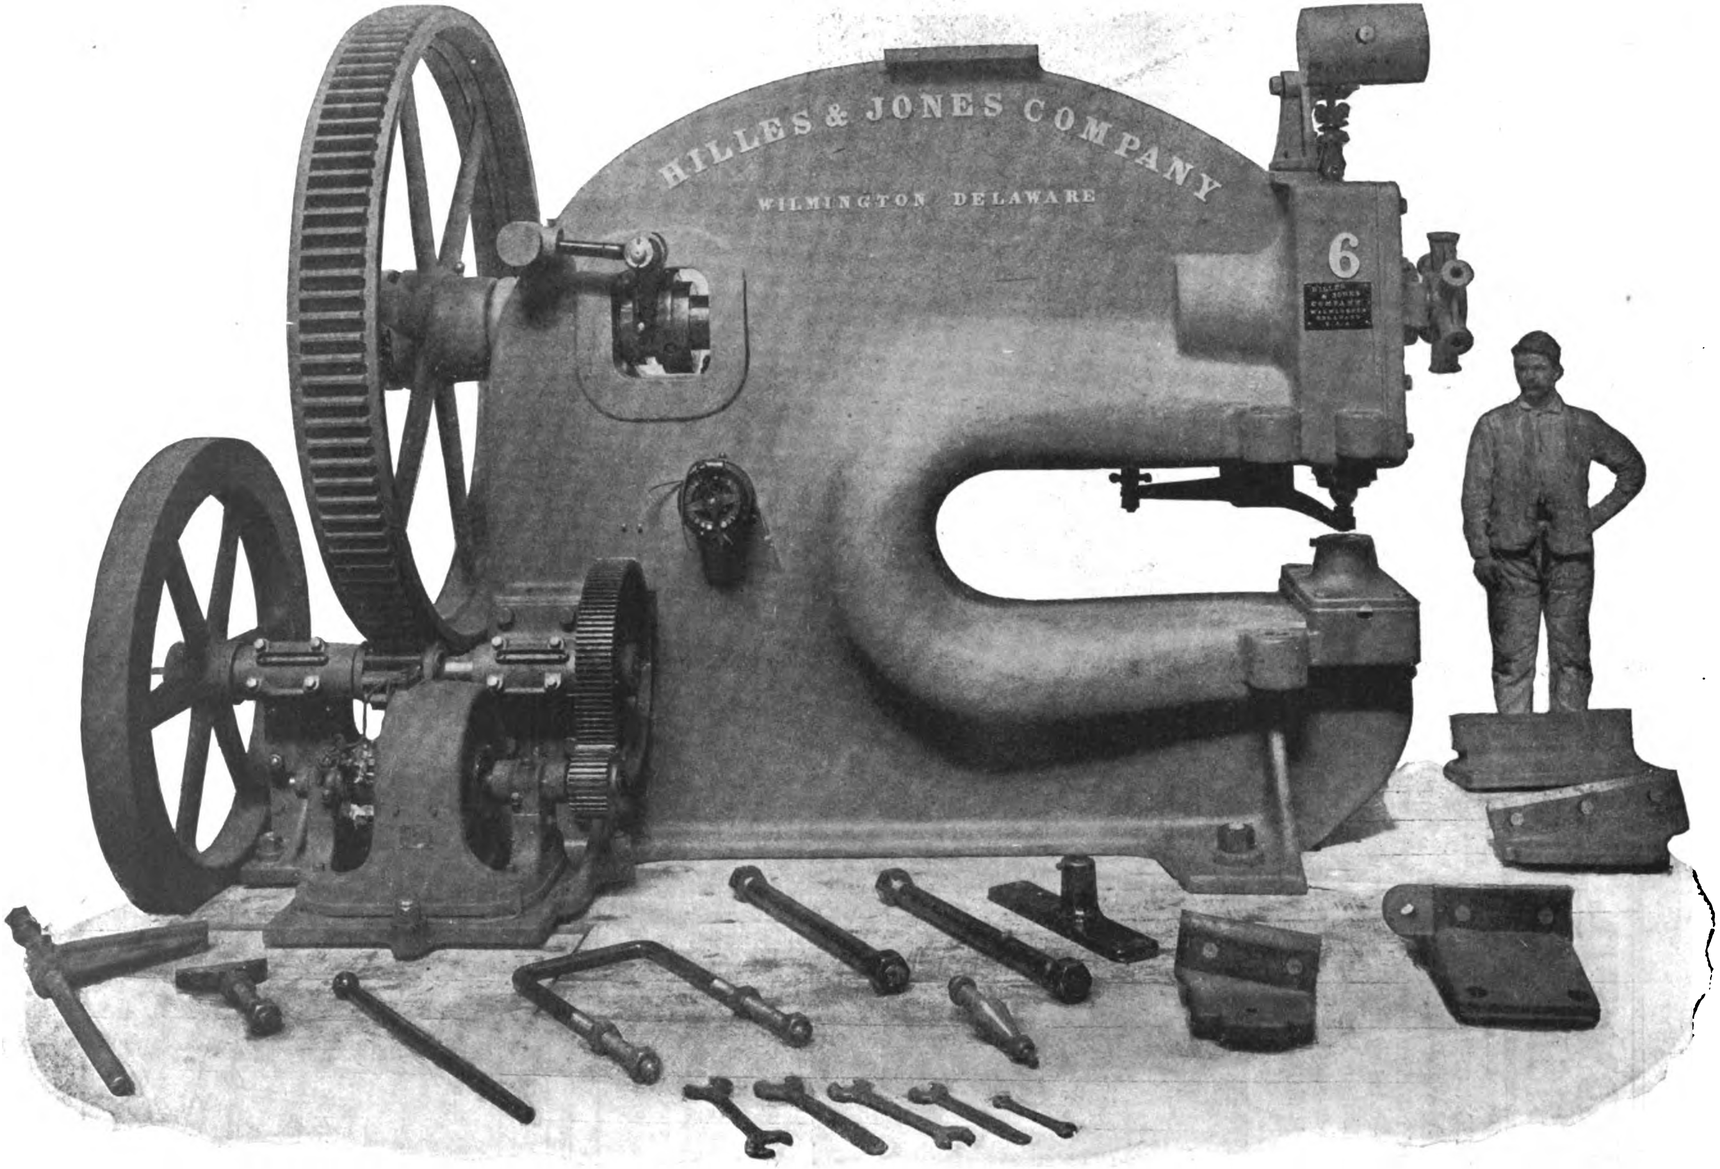
Turning to Fig. 1, the cables crossing the bridge may be enumerated as follows:

To Pittsburg Reduction Co. and Niagara Electro-Chemical Co., four 950,000 cm., lead-covered, made by the General Electric Co.; to the Carborundum Co., two 1,000,000 cm., lead-covered, made by the General Electric Co.; to the Acetylene Light, Heat and Power Co., two 1,000,000 cm., lead-covered, made by the General Electric Co.; to the Buffalo and Niagara Falls Electric Light and Power Co., four 300,000 cm., lead-covered, made by the Washburn & Moen Mfg. Co.; to the Buffalo and Niagara Falls Electric Railway Co., one 1,000,000 and two 500,000 cm., lead-covered, made by the General Electric Co.; to the Niagara Falls and Suspension Bridge Railway Co., five No. 0000, lead-covered, made by the John A. Roebling's Sons Co.; to the local street railways for track return, two 500,000 and one 1,000,000 cm., bare cable, made by the John A. Roebling's Sons Co. All of the above are led into the subway. Besides these, there are four 1,000,000 cm., of General Electric make leading to the step-up transformers on the Buffalo transmission line, and three 350,000 cm., made by the General Electric Co., bare cable, on the overhead line running to Buffalo from the transformer building.

Fig. 2 gives a faithful picture of the local subway with the cables in place, open to ready inspection and access. Of this subway there is a good half mile to the first large group of



ELECTRICALLY DRIVEN PUNCH AND SHEAR, BUILT BY THE HILLES & JONES CO., WILMINGTON, DEL.

factories shown in Fig. 3. Taking the users in rotation as indicated by the numbers on the map, they run as follows: No. 1, Carborundum Co., 1,000 electric horse power; No. 2, the Pittsburg Reduction Co., 3,000 e. h. p.; No. 3, the Mathieson Alkali Co., 2,000 e. h. p. and 600 e. h. p.; No. 4, Niag. Electro-Chemical Co., 350 e. h. p., and 1,000 e. h. p.; No. 5 Acetylene Light, Heat and Power Co., 500 e. h. p.; No. 6, Chemical Construction Co., 500 e. h. p:; No. 7, Albright, Wilson Co., 300 e. h. p.; No. 8, Buffalo and Niagara Falls Electric Light and Power Co., 500 e. h. p.; No. 9, Niagara Falls Water Works, 50 e. h. p.; Niagara Falls and Suspension Bridge Co., 250 e. h. p.; Buffalo and Niagara Falls Electric Railway Co., 300 e. h. p.; No. 10, Niagara Falls Paper Co., 3,300 hyd. h. p. This makes a total of 13,650 horse-power for local consumption, of which quantity that used beyond the subway is, or will be, distributed on pole lines. It will be noted that No. 7 factory has gone a considerable distance from the power house, and one of the interesting features of the development in the future will be the way in which the industries scatter wider and wider afield and the growth of population around the new centers of industry.

ELECTRICALLY DRIVEN COMBINED PUNCH AND SHEAR.

THE illustration on the opposite page represents an interesting application of electric motor driving as adapted to tools of the heaviest kind and subject to the severest duty. It shows a combined punch and shear manufactured by the Hilles & Jones Company, of Wilmington, Del. This massive and substantial tool is capable of punching 6-inch holes in ¾-inch steel.

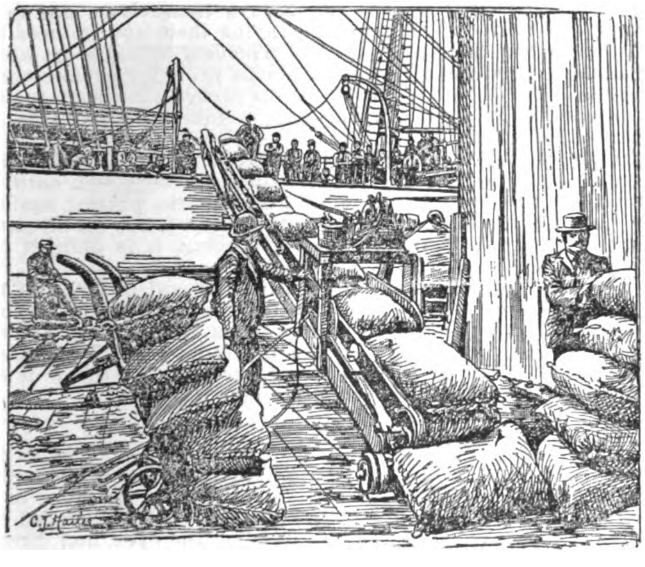
The machine frame is of box form throughout and weighs nearly 40,000 lbs. in a single casting. It is well adapted for shearing plates and bars as well as punching, the knife blocks being secured to the nose and the sliding head by through bolts and tongues so that they can be readily removed without injuring the main frame. The sliding head is counterbalanced through a spiral spring and has a tapered brass shoe for taking up the wear. The spur wheel is large, with turned shrouds, the clutch which engages with this being controlled by an improved adjustable automatic stop which allows the sliding head to be brought to rest at any desired point of the stroke. The motor is mounted on an extension base connected to the main frame and drives on to the fly-wheel shaft through a pair of cut gears. This method of construction takes up but very little floor space, considering the capacity of the tool, and makes it entirely self-contained. It avoids also any pipes or belting which might interfere with overhead traveling cranes and has proved itself an economical and most satisfactory method of driving.

At the time the work is being done on machines of this class, there is a momentary slowing up which, of course, sends more current through the motor. Hence, as a rule, for this class of work, the compound wound motor is found most serviceable. For punches and shears, especially, the speed is constant; for bending and straightening rolls some variation would not be material.

LOADING SHIPS BY ELECTRIC POWER AT TACOMA, WASH.

NOT long ago 2,500 tons of flour—an ordinary cargo—was loaded on one of the Northern Pacific's oriental steamers in twenty-four hours. This is scarcely an unusual occurrence at Tacoma, where 2,000 tons of cargo are loaded or unloaded in twenty-four hours very frequently.

An important factor in this record-breaking work is a new electric conveyor for loading and unloading vessels, invented by Messrs. McCabe & Hamilton, the stevedoring firm which handles all the business of the Oriental steamers and wheat ships visiting that port. Realizing the need of such a conveyor, Mr. McCabe and Mr. Hamilton both devoted considerable thought to the problem during the summer of 1895. They finally gave up all notion of using complicated apparatus and decided to try a very simple device which their judgment recommended. With this conveyor Tacoma's splendid record for the fast dispatch of vessels has been established. It was used for the first time in loading flour on the Northern Pacific steamship Strathnevis in October, 1895. The accompanying illustration shows the conveyor at work.



LOADING SHIP BY ELECTRIC CONVEYOR.

With this apparatus flour and grain can be loaded at any stage of the tide, and without reference to the weather, for should it rain a canvas is quickly spread from the door of the warehouse to the ship's hatch. With the system of loading in vogue elsewhere about eighteen men are required to do the work done by this conveyor, with which the bags are delivered into the ship's hold at the rate of 2,500 to 2,700 pounds a minute, or seventy-five tons per hour. When speed is desired two conveyors are used, as was done when the record of 2,500 tons in 24 hours was made.

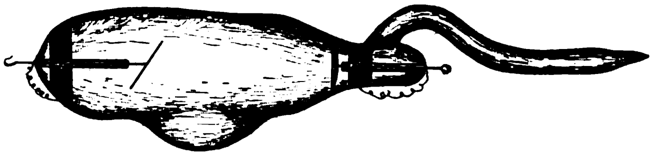
The electric conveyor is about forty feet long. Two wheels in the center allow it to be moved at will. A two-horse power motor supplies the power, the current being taken from the Tacoma Railway and Motor Company's wires. The revolving belt on which the sacks are placed is of rubber and passes over twelve rollers. The belt is propelled by a driving wheel attached to the side of the apparatus. The rollers are placed close enough together and the belt revolves at such speed as to carry all the weight in flour or grain that can be placed upon it. The conveyor works as well when placed at an angle of 45 degrees as when on a level.

ROENTGEN RAYS

HOW TO KEEP X-RAY TUBES IN CONDITION WHILE WORKING.

BY MAX OSTERBERG.

THE Röntgen rays have certainly arrived at a stage at which the subject may be considered a separate branch of the science of electricity. It is a subject which the engineer, the physicist, and the physician or surgeon should take up conjointly in order to bring it to that stage of perfection which is desirable, and in fact necessary. Every one who has the opportunity to experiment should consider this a duty to his fellowmen, and even without pecuniary gain in view, the time spent over this class of work will repay the worker by giving him the satisfaction of having at least done his share in helping hundreds, aye, thousands of the most deserving and most unhappy of his fellowmen, the crippled and injured. The physician has a field of his own; his work should be devoted principally to investigate by means of the fluoroscope, and in those weird shadows read the condition of his patient. The physicist must devote his time to improving means of obtaining good effects brought about in any manner, whatsoever, no matter how complicated or how simple, while the engineer should take the role of the economist, and try to lower the expense of constructing and running the apparatus, as well as devise ways and means to handle the apparatus with ease, and in spite of necessary complications have it arranged so that a layman with ordinary intelligence can handle it. All this is not new, but it cannot be impressed too frequently, nor too strongly. To those who feel as enthusiastic as I do I need not apologize for this moral urging; to those who are so unfortunate not to appreciate this keen desire to lend a helping hand, I do not want to appologize.



OSTERBERG'S METHOD OF CONTROLLING ROENTGEN TUBES.

During the last few months I have more than ever felt the desirability to preserve one tube as long as possible for more than one reason, and the money question was by no means the most important one. After working a tube for some little time, one becomes thoroughly familiar with it, and only commences to do satisfactory work with the same. The position of maximum effects, the color of the fluorescing glass, the amount of heating during a certain time, remain practically constant, and therefore nothing but practice is required to manage that part of the manipulating. You open your switch to allow the tube to cool from time to time, just as instinctively as you fold your napkin after a meal; you hold your fluoroscope in the right position without special thought, and thus can concentrate your entire attention on the investigations which you happen to be undertaking.

After a while, however, the vacuum in the tube goes up, and you have to devise means for again reducing it to that stage at which it works most satisfactorily. Reversing the current in the tube is but an apology for a cure, since it blackens the bulb, thus absorbing too many efficient rays. Heating the tube with a Bunsen burner, or an alcohol flame is a much better method, but it lasts but a comparatively short time. Of late I have been successful in finding a method to prolong the life of a tube which is bound to prove a valuable aid in many cases.

I found, while working with sheets of tinfoil connected to the secondary of the coil, with the intention of investigating capacity and condenser effects in the secondary, that by attaching two small rings of tinfoil around the tube just at the place to which the anode and cathode extend, and then connecting one ring to the anode, the other to the cathode terminal that the tube will again fluoresce for many hours, in fact, I have not been able to work a tube a sufficient length of time to raise the vacuum so as to make it useless under this method.

The voltage required to produce good effects decreases considerably; while I used 12 volts to run the tube successfully, I needed but 4 to get as fine a Röntgen ray after I had a high vacuum, with tinfoil rings around the tube. Care should be taken to attach the rings properly and neatly, for otherwise too much distortion of the cathode rays which are reflected from the anode will take place and give a blurred Röntgen ray image. If working with a sufficiently high voltage in the primary this can be easily investigated, for while it is possible to get the platinum anode red hot when the tinfoil rings are put on neat and clean, this will not be possible when they are just put on carelessly. A rubber cap lined with tinfoil, made to fit the terminals of the tube will prove a valuable aid. This cap can be put on as soon as the tube commences to weaken. I suggest this rubber cap so as not to expose the edges of the tinfoil to the atmosphere, as this causes a considerable amount of leakage, which means just so much loss of energy.

OXYFLUORIDE OF URANIUM AND AMMONIUM, A NEW X-RAY FLUORESCENT.

BY FREDERICK S. KOLLE, M. D.

CONSIDERABLE interest has been aroused by the announcement of the above new chemical compound, introduced by Dr. Van Melckebeke, at the Société Medico-Chirurgicale of Antwerp. From personal experiments with the new fluorescent, I can certainly vouch for the compound. In Germany and England, radiographers still adhere to the use of the potassium platino-cyanide in preference to the calcium tungstate of Edison, but the above oxyfluoride will probably replace both within a short time, until some new or more powerful compound is discovered.

The product obtained differs from the Wurz double fluoride of uranyl and ammonium, having the following formula: $Ur_2O_2Fl_2NH_4Fl$, in that the precipitation of its microscopic octahedral crystals, are formed by a greater amount of ammonium fluoride, the relation being about one part of the latter to two parts of the uranium nitrate, with a formula of $Ur_2O_2Fl_24NH_4Fl$; the chemical reaction being expressed as follows:

$$2(UrONO_3 + 3H_2O) + 6NH_4Fl = Ur_2O_2Fl_2, 4NH_4Fl + 2NH_4NO_3 + 6H_2O.$$

The preparation of this oxyfluoride to obtain best results, is made as follows: Take (1) ounce of uranium nitrate c. p. (Merck's reagent), and allow it to dissolve in (4) four ounces of water, which is brought to a boiling point in a porcelain evaporating dish, over a sand bath, using the Bunsen flame. The uranium will solve readily, leaving a straw-colored liquid, to which add gradually one-half ounce of ammonium fluoride c. p. (Merck's reagent), and allow the two to boil a few moments. Fumes of ammonium nitrate will be given off.

The solution should not contain any sediment and is then set away to cool and crystallize; this takes place in about one hour or more, when the liquid will have lost its yellow color and appears like water. At the bottom of the dish a yellowish sediment, not unlike flowers of sulphur, will be seen, which, when examined by the microscope, will be seen to be octahedral crystals.

Their fluorescent property depends upon perfect crystallization. The liquid above the sediment is decanted and the latter washed two or three times with clean cold water, to remove all nitrate of ammonium. The oxyfluorides are insoluble in cold water, but readily dissolved in hot water. The sediment may then be collected and dried upon filtering paper.

The amount obtained, using the above method, will be about 128 grains, at a cost of 62 cents, being considerably cheaper than any other fluorescent compound now used, with any success. Owing to the minuteness of the crystals, excellent results taking the usual granular appearance, can be had by lezing a screen prepared with the above in consort with the gelatin film of the dry plate, to shorten the time in making a radiogram.

In comparison with other fluorescent salts, it ranks next to fused pentadecylparatolycetone and is about 7 per cent. better than the caleic preparation. The crystals when dry can be mounted with flexible collodion or gelatin, as in the other screens.

A PREVENTIVE FOR X-RAY BURNS.

THERE have been many reports from various parts of the country that long exposure to X-rays had caused acute maladies of the skin, accompanied by great pain, and that the hands of X-ray operators were swollen and inflamed and that the finger nails often dropped out.

Dr. Danforth Cole, of Minneapolis, corroborates these reports by his own experience. Consequent upon his work around the powerful rays he has lost half a dozen finger nails, his hands were swollen and inflamed, and the right forearm is badly burned. The last-mentioned wound was received while the arm was sheltered by the usual amount of clothing, which was in no way affected. The skin is very red and full of fever and the affected part is slightly swollen.

Dr. Cole was greatly puzzled at first by these undesirable concomitants of the use of the X-rays. He was also much dismayed, because it seems probable that in taking radiographs of sore or diseased parts the trouble might be greatly aggravated by the irritating influence of the rays, which shows itself slowly and lasts a long time. In fact, one patient complained that the soreness in a lame joint was much increased immediately after exposure to the rays, though the exposure was not long enough to have a lasting effect.

Investigation showed, says the Minneapolis "Journal," that the harm was not due to the X-rays themselves, but to a static electrical discharge accompanying them and induced by the bodily warmth of the subject. The heat of the body, while inducing the discharges, is not potent enough to make them visible, but when an alcohol lamp is brought near to the Crookes tube, the feathery discharges into the flame may be clearly discerned.

Having ascertained the cause of the trouble, it was easily overcome. Dr. Cole now uses an aluminum screen which entirely shuts off the static discharge and ensures the patient against burns. But as the operator's hands are constantly on all parts of the apparatus, adjusting and arranging, it is difficult for him to get complete immunity himself.

Dr. Cole also claims to have made several discoveries regarding the use of electricity, including X-rays, for carrying medicines into the body, his idea being that healthy tissues will eliminate the medicine without anything more than temporary effect, while the diseased tissues cannot throw it off so easily; hence the medicine is placed effectually.

A PEN LIGHT.—The "Optician" gives an account of an invention by a man named Wilcox, in which a minute incandescent lamp is fastened to a pen near its point in order to illuminate the writing. "A little reflector," it says, "placed behind it, prevents the light from dazzling the eyes, and directs it toward the paper, This arrangement . . . may be applied also to a pencil or to any instrument of the same sort."

THE BURTON ELECTRIC SMELTING CO., has been formed at Portland, Me., with a capital stock of $1,000,000 of which $60 is paid in. The object is to make, deal in and operate electric smelting apparatus. G. D. Barton, of Boston, is president, and H. D. Tudor, treasurer.

ELECTRIC LIGHTING

THE BOSSERT SHEET STEEL SWITCH BOXES.

THE use of cast iron for wall, outlet and switch boxes for conduit work has been the subject of some important discussions by electrical engineers and contractors. These boxes have generally been made of cast iron with holes cut in various places for the insertion of conduit, and for the want of something different or better have been in general use. One criticism which has been made is that if the construction man desired to enter the box at a different place with the conduit than the hole provided, he had either to break another hole in the box, have one drilled in or finally to discard the box altogether or find a new. A further argument against cast iron boxes has been that many of them break while being placed in position and are oftentimes left there by careless workmen

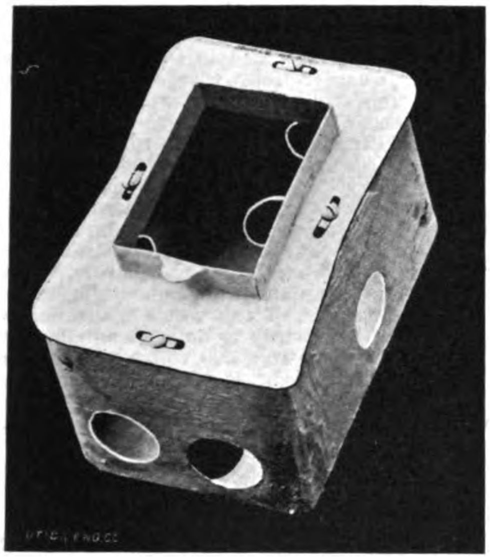


FIG. 1.

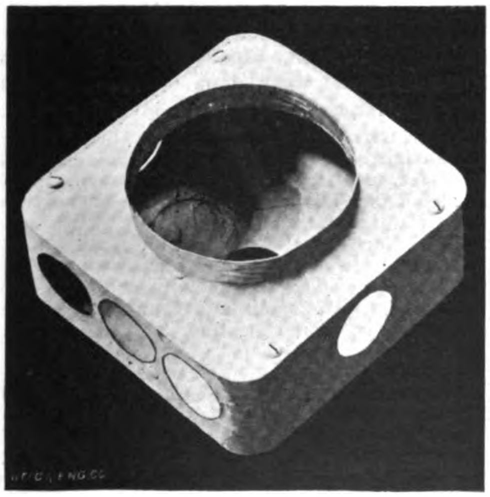

FIG. 2.

The Bossert Electric Construction Company, of Utica, N. Y., believing that a better material and one which was absolutely indestructible might be secured, and that a more convenient form of construction of these boxes could be found, have recently made a decided innovation in these goods. All their forms of switch, wall and outlet boxes are drawn from one piece of sheet steel. They also provide in these boxes a number of holes in the sides and bottom which are securely pluggedup again and areguaranteed to be water-tight and fireproof. Hence, should the workman choose to enter the box from a different point from that on which he had calculated, he has but to drive out the steel plug at the point he desires. Holes are made for any size conduit and the boxes are heavily insulated. This company also make a special steel drawn switch box for the Cutter switch, the Hart switch and the Gibbs switch, provided with holes in the same manner as above described. This new appliance is admirably illustrated in Figs. 1, 2 and 3. Claiming as they now do that these boxes are the best, the cheapest and most convenient of any now upon the market, general approval may be expected.

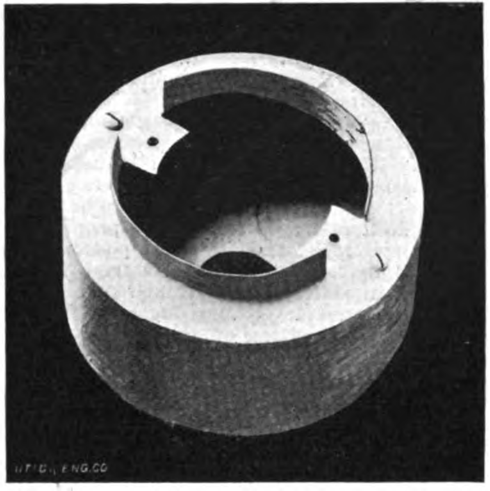

FIG. 3.

The Bossert company also make steel clad slate lined junction boxes and distributing boxes of every description, marine and underground boxes, and, in fact, any box which an electrical contractor may be required to furnish.

INSURANCE AS AFFECTED BY ELECTRICAL CONSTRUCTION.

BY G. S. McLAREN.

IN giving a paper on electricity as viewed from an insurance standpoint, I desire briefly to discuss the position taken by the underwriters in regard to its use and to mention a few of the greatest dangers to be avoided. Immediately that insurance is suggested as a subject, either for conversation or as the topic of a paper, there arises a loud and prolonged wail against these grinding, far-reaching monopolists. The trouble with us all is that each thinks everyone else is making too much money and that he is making too little. The insurance companies do the same as any commercial house. They try to write a large number of risks, and probably owing to the peculiar nature of their business they protect it more than any other organization. It is for these reasons that insurance companies have organized an electrical inspection department, trusting that by so doing they will benefit the insured and therefore better protect themselves. It seems to me that the more insurance companies insist upon good, practical, safe wiring and use of electrical apparatus, the better it will be for the central station owners, the supply men and all concerned.

Let us take first the benefit to the station owner of a careful inspection of electrical equipments. When a building is being wired he does not have to keep a man constantly watching the work to see that it is done correctly, but when the time comes to connect the installation to his system, he simply inquires if the work has been approved by the underwriters, and upon an affirmative reply, the connection is made. But that is only the beginning; he knows that the building is inspected ever so often; he knows that there is some one constantly on the lookout for trouble and defects

---

[1] Abstract of a paper read before the Northwestern Electrical Association Jan. 20, 22, 1897.

over his entire system, and even watching the work of his own men, and many a leak and many a cause for serious trouble is brought to the notice of station owners by insurance inspectors.

And how evident it is to us all that the less trouble there is on an electrical system the cheaper it can run. If the mains and branches throughout the building are large enough to amply carry the current, and if there is no leak in the insulation, you can certainly furnish cheaper and more satisfactory light.

Then again the person erecting a building receives a great benefit from the underwriters in the electrical line as well as in many others. He knows in the first place that there will be no danger from the wiring, and that the work will be done according to the most approved ideas. He has, gratis, someone who watches his contractors and their workmen, and who is constantly looking out for his interests, and he always has the satisfaction of knowing his equipment is thoroughly surveyed at least once a year. Even the supply man and the contractor (provided they sell good material and do good, careful work)) are aided by the insurance companies, for the underwriters are always ready to recommend the best goods and the most reliable workmen.

I would like to ask if, as an association, we cannot do something to raise the standard of electrical work and electrical workers. Why should there not be as severe a law in regard to the efficiency of electrical workers as there is concerning plumbers? Why should contractors be allowed to hire small boys to do a man's work? Many people consider that the greatest danger to be avoided is the possibility of a direct short circuit. I do not believe this is true, for it has been my experience that short circuits almost invariably take care of themselves by immediately blowing a fuse or melting one of the wires and thus cutting off the current.

More important points in wiring are, the correct location of fuses, the grounding of wires, the wiring of fixtures, the use of flexible cord, and the placing of inflammable material near electrical apparatus. Let us discuss them briefly in the order mentioned.

Cutouts should be centrally located, of easy access, and entirely separated from inflammable material. They should never be scattered promiscuously throughout a building. Then where a wooden cabinet is used to hold cutouts, you will often see the back and sides of the cabinet lined with asbestos, while the door, which closes almost against the fuse, is left bare. I do not believe in even placing fuses in the canopies of fixtures or in rosettes for cord drops, especially not in damp places.

Slow leaks and the grounding of wires on gas and other pipes cause a considerable loss each year. They do not take sufficient current to blow a fuse, but instead either form an arc or slowly work on the surrounding substance until they have become thoroughly charred and at last ignited.

I have as yet failed to find an entirely satisfactory wire and insulation for fixture work. If some manufacturer would introduce an insulation of small diameter, which could not be easily cut, and was still moisture proof, it would find a ready market. The fixture men should use more care that all burrs are removed from the fixture stems, that the insulation is not peeled from the wire by drawing it through the fixture, and that their joints are correctly made.

The use of flexible cord in electrical wiring is a matter of much concern to the underwriters. The number of fires caused by its use is surprising. We are now advocating the use of a cord with a solid rubber insulation of at least 1-32 of an inch in thickness, which in turn shall be covered by a braid. The principal troubles with cords occur in show windows and in draping designs in stores. Electric lights certainly look very pretty peeping out from under a mass of cotton batting or from a pile of ribbons, but that such use of them is dangerous few seem to realize. The danger arises from three sources, namely, bad insulation of wire and defective strand; defective lamp sockets, and direct heating effect of the lamps. Several examples of the latter were mentioned.

There are many more points in the use of electrical apparatus which cause trouble and which might be brought up for discussion, but I think four-fifths of the electrical fires originate from those mentioned.

In closing I would like to speak of the actual insurance of buildings and the effect electrical wiring and apparatus bear on the "make up" of their rates. To explain more fully I will briefly give an outline of how rates on buildings are determined. First please understand that buildings are not rated by any mere guesswork; they are compiled by carefully consulted, accurate tables which have been deduced from statistics taken of all fire losses that have occurred for many years.

To illustrate this, the basis rate on a four story building, whose area is not over 3,000 square feet, is 55 cents. If the building has a larger area, we add five cents for each 1,500 square feet or fractional 500 square feet. If the building has deficient walls five cents is added for each story where they are deficient. Ten cents is added for a shingle roof and five cents for wooden cornices. For skylights, well holes and stairways we add five cents each, and for elevators 10 cents. Adjoining buildings cause an exposure rate of from 5 to 20 cents or even higher, to be added. To all this is added a rate for the occupancy. Then the improvements on the risk are considered. Ten cents are taken off for electrical alarm connected with fire department, 5 cents for combined standpipe and ladder, 10 cents for automatic hatchways, 20 cents for watchman and clock, etc. The deficit rates are then added and from them is deducted the sum of the amounts taken off for improvements. The result is the rate charged.

As electricity is comparatively a new feature in insurance there are comparatively few statistics in regard to losses from its use, so it would be almost impossible to state how much increase should be added to the rate on a risk where, for illustration, weather-proof wire is used instead of the best grade of rubber insulation, or when no spark arresters are placed on the arc lights. Moreover it would necessitate large tables and considerable trouble to add or deduct very small percentages from a risk for every defect or improvement in electrical apparatus, therefore, it has seemed best to have a standard or set of requirements governing all electrical equipments and to require that this standard be strictly enforced. Where it is not carried out the insurance is cancelled. There are a few exceptions to this rule, viz., where the general condition of the plant is not good a decided increase is sometimes added instead of the whole insurance being cancelled. This more frequently is done in smaller towns than in large cities. Then where a 500 volt current from the trolley wire is used one per cent. is added to the regular rate.

ELECTRICAL SUPPLIES.[1]

BY W. W. LOW.

THE author made some pertinent remarks on the maintenance of the electrical supply business, giving some practical hints derived from his own experience. He dwelt on the advantages of membership in the association, and the pleasure derived from attending its meetings. He claimed that the supply man is at once the guide, philosopher and friend of the central station manager. Their interests are identical, and there are many ways in which they can work together for their mutual benefit, especially in the discountenancing of bad practice in their trade relationship. He predicted that in a few years, it will be much easier than at present for the central station buyer to know exactly what he wants for every purpose, and what the price should be. He urged the members of the association to do their utmost to bring about such a condition.

ELECTRICITY IN OMAHA.

The annual report of City Electrician Schurig affords a very thorough detail of the work done by the electrician during 1896 and of the improvements that have been accomplished in the electrical wiring of the city and in the removal of superfluous and unsightly poles and wires. The report shows that 193 permits for electric wiring were issued. Under these were installed 5,066 incandescent lamps, fifty-five arc lamps and seventy-four motors and dynamos, with a combined capacity of 897 horse-power. Under the direction of the electrical department 440 miles of aerial wire were removed from the streets and ninety-seven poles were taken down. The wires of the Nebraska Telephone Company in the business district were placed under ground, 825 miles of wire being thus removed from the streets.

A portion of the report is devoted to municipal lighting. The electrician says that he has made inquiries of the officials of other cities in regard to the expense of their public lighting and has been convinced that the present contract in Omaha is a fair one for the city.

Some extensive improvements are recommended in the fire and police alarm department. In the first place a chloride storage battery is wanted in place of the gravity battery now in use. The latter costs about $400 per year to operate and requires the attention of one man the greater part of the time. The operation of the storage battery would not cost over $60 per year and would give far more satisfactory service. The cost of making the change, including the purchase of a new charging switchboard, is estimated at $850.

---

[1] Abstract of a paper read before the Northwest. Elec. Assoc.

THE ENCLOSED ARC LIGHT.—III.

BY L. B. MARKS, M. M. E.

Having thus reviewed the fundamental conditions governing the operation of enclosed arcs, we will now confine our attention to the most important phase of the subject, namely, the high potential enclosed arc.

"Pioneer" (Marks) High Potential Enclosed Arc Lamp.—We have seen that all the types of enclosed arc lamps described up to this point have been deficient in various particulars. As far as commercial operation is concerned, none of them has been a success. It remained for a lamp operating on a new principle to fulfill the requirements exacted by the commercial practice of the day. Such a lamp had to satisfy the following conditions: First, standard steady light of uniform distribution; second, efficient arc; third, long life of the carbons; fourth, no blackening or discoloration due to the disintegration of the carbon.

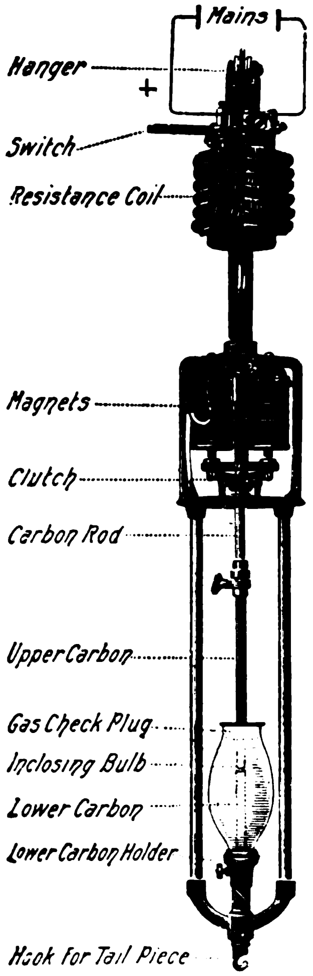

Fig. 4.

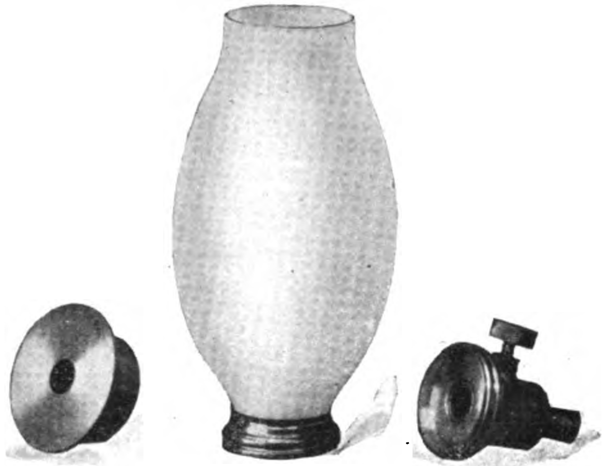
These conditions were fulfilled in a lamp, an account of which I presented for the first time before the National Electric Light Association of America in February, 1894, and which I called the high potential incandescent arc. The high potential enclosed arc, as its name indicates, was so called on account of the high voltage of the arc. High voltage is of course a relative term and is applied in this case in contrast to the usual voltage of the arc, viz., 40 to 45 volts. In experimenting in this line I found that arcs could be steadily maintained at double the voltage of the ordinary arc, and under some conditions even at three or four times the voltage. Arcs of such high voltage are naturally quite long, and require apparatus specially adapted to operate them. I found that under proper conditions these long arcs could not only be maintained continuously, but so operated with a remarkably small current thus resulting in high efficiency and long life of the electrodes. Experience has shown that this method of operation is the only one which has been successfully applied to existing commercial circuits. A glance at Fig. 4 in which marginal notes indicate the principal parts of the lamp will show that the operating mechanism consists simply of a pair of solenoids; armature and cores; lazy clutch and carbon rod. This mechanism is designed so as to spring a long arc of about 10 millimetres or more. The design of the solenoid is such that the current consumed by the lamp will be very small and quite uniform throughout the range of the lamp. The enclosing bulb is mounted in the lower carbon holder and, as will be seen from the notation on the cut, is closed at the top by a special device known as a gas-check plug. The lower carbon in this lamp is 12 centimetres long and the upper carbon 30.5 centimetres long; both pencils have a diameter of 11.11 millimetres. At the top of the lamp is mounted a small resistance coil. The standard lamp is designed to pass a current of from 4 to 5 amperes, 80 to 85 volts being the drop across the arc. Fig. 5 shows the bulb and gas check plug in perspective.



Gas-check Plug; (fits in mouth of Bulb). Enclosing Bulb; (surrounds the Carbons.) Lower Carbon Holder; (supports the Bulb.)

Fig. 5.

The Gas-Check Plug.—The plug which forms a closure for the bulb is such a unique device that I have deemed it worthy of a special representation in another illustration, Fig. 6, where you will note the gas-check plug is shown in cross section mounted in the mouth of a cylinder. If we close the mouth of the bulb simply by a flat metal disc having an opening in it sufficiently large to allow for variation in diameter of commercial carbons, we find it difficult to prevent an abnormal access to oxygen into the enclosure. The gas plug was

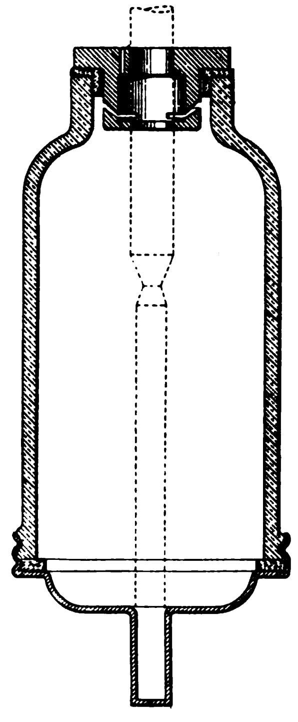


Fig. 6.

devised to check the circulation of ingress and egress and still have the same sized opening leading into the enclosure. The comparative measurements with and without the gas-checking device will be given later on.

It will be noted that in order to retard or check the flow of gases into and out of the bulb, the plug is provided with a depending cylindrical metal tube about 1½ centimetres long, the lower end of which is slotted so as to allow of communication between the gases on either side of the wall formed by the tube. The opening around the carbon may with advantage be enlarged so as to form a secondary chamber for the gases, as shown in the cut. Now after the lamp has been in operation for a few moments, the heated gases from the arc instead of having an unobstructed egress, are met by another body of gas at the plug, resulting in the production of eddy currents which tend to check the circulation of the outgoing and incoming gases. I have in my hand a model illustrating the principle of the gas-check plug. Instead of the lower carbon I use an ordinary wax candle. Instead of the upper carbon I use a strip of metal to serve as a longitudinal diaphragm adapted to show the circulation of the gases. The depending cylindrical metal tube which projects into the bulb is provided at its lower end with slots just as explained before. In order to show the gas-checking action very distinctly I have arranged to open and close the slots at will. The conditions you will see represent exactly those which exist in the case of the lamp. I now light the candle. If I remove the metal strip which forms a dividing wall for the gases, the circulation of air into the enclosure will be stopped almost instantly and the candle goes out. If the strip be inserted, thus representing the upper carbon in its normal position in the lamp, and the candle be relighted, you will note that the flame continues to play, the cool air finding a path for admission on the one side and the heated gases having an unobstructed egress on the other. Thus far the slots in the depending tube have been closed. I now open these. You will note that the circulation of gases is quickly checked and the flame grows dimmer and finally becomes extinguished. The heated gases are diverted in their course, and instead of passing freely out of the enclosure, tend to fill the bulb with a deoxygenated atmosphere, thus illustrating the action of the gas-check plug of the enclosed arc lamp.

TABLE III.

LIFE TESTS WITH AND WITHOUT GAS-CHECKING ATTACHMENT. CARBONS 11.11 MM. ($\frac{7}{16}$ IN.) IN DIAMETER.

Mean current. (amperes)	Mean arc tension. (volts)	Mean energy. (watts)	Consumption of (+) carbon per hour in mm.	Consumption of (—) carbon per hour in mm.	Total consumption of carbon per hour in mm.	Remarks.
7.98	63.86	509.65	2.118	.538	2.656	No gas-check.
7.99	63.4	506.56	1.483	(—).152	1.331	Gas-check
8.03	61.77	496.12	2.751	.424	3.175	No gas-check.
8.06	63.5	511.81	1.161	(—).076	1.085	Gas-check

TABLE IV.

Life Test of Carbons 11.11 mm. in diameter, in "Pioneer" 5-ampere enclosed lamp.

" " (+) carbon = 109.537 "
Original length (+) carbon = 306.387 millimetres.
" " (—) carbon = 121.10 "
Final " (+) carbon = 109.537 "
" " (—) carbon = 82.55 "
Total run = 121. hours.
Consumption (+) carbon per hour = 1.652 millimetres.
" (—) " " " = .319 "
Maximum current = 5.25 amperes.
Minimum " = 4.65 "
Average " = 4.95 "

Life Tests.—First, with and without gas-checking attachment. The use of the gas-check plug makes it possible to prolong the life of the carbons far beyond that which can be reached without employing this device. In the accompanying Table III. I give the results of tests made with and without the gas-checking attachment, other conditions being practically the same. You will note that in one of the tests the total consumption of carbon with the gas-checking plug was only a trifle over one-half and in the other a shade more than one-third of that resulting from the omission of the gas-checking attachment. The prolongation in the life of the negative electrode was exceedingly marked, the latter having increased in length in each case when the gas-checking attachment was used.

Second, with carbons 11.11 mm. in diameter in 5 ampere lamp. A pair of carbons which in the ordinary open arc will burn from 6 to 8 hours, will last from 100 to 150 hours in commercial practice in the high potential enclosed lamp which I have already described to you. A life test of a pair of carbons 11.11 mm. in diameter, operated in the standard lamp is given below. This is a report on the performance of a lamp, which is in service about four hours every day. The total run was 121 hours. See Table IV.

Third, with carbons 12.7 mm (½ inch) in diameter, in 4 ampere lamp. When the diameter of the carbons is increased the longevity is greater, but other objections are introduced which will be treated of under the heading of "Efficiency of the Enclosed Arc." The life test of a pair of carbons 12.7 mm. in diameter running about 12 hours per day in a 4 ampere lamp is given in Table V.

TABLE V.

Life test of carbons 12.7 mm. in diameter, in "Pioneer" 4 ampere enclosed arc lamp.

Original length (+) carbon = 304.80 millimetres.
" " (—) carbon = 128.587 "
Final " (+) carbon = 114.30 "
" " (—) carbon = 77.787 "
Total run = 199. hours
Consumption (+) carbon per hour = .957 millimetres
" (—) " " " = .255 "
Maximum current = 4.5 amperes
Minimum " = 3.8 "
Average " = 4.15 "

LIGHT; ITS DISTRIBUTION AND DIFFUSION AS RELATED TO QUALITY AND EFFICIENCY.—II.

BY E. LEAVENWORTH ELLIOT.

THE lighting engineer—a hypothetical personal who we hope will actually exist some day—has at his disposal five different light sources—viz., the oil lamp, gas flames, incandescent gas, incandescent electric and electric arcs. With the exception of the incandescent electric, all these must be placed in a vertical position, and except the electric arc cannot be inverted. Now, it is a common idea, due to some extent perhaps to a careless statement in the text books—to-wit: "from a given source light proceeds equally in all directions," that such is actually the case, when in fact it is not the case at all. Each source of light distributes its rays according to its own peculiar law. These laws are most easily expressed as polar curves, which are given in Fig. 1, the plane of the curve being vertical.

It will be observed that the lights produced by gas and oil send a large part of their light upward: the direct current arc sends most its light downward, the larger part included between the angles of 30 degrees and 50 degrees; while the alternating arc sends its light equally upward and downward, but mostly between the angles of 50 degrees above and below the horizontal; while the distribution from the incandescent electric is by no means uniform it is of less importance since the lamp may be placed at any angle. With the exception of the flat flame, the distribution of all these sources in a horizontal plane may be considered uniform.

The objects which we wish particularly to illuminate are generally below the level of the eye, as reading matter, or articles being worked at with the hands. In practically all cases they are below the sources of light. The first step toward efficiency and economy will be therefore to direct the larger part of the flux of light below the plane of the source. In exterior lighting we may consider all light above this plane as absolute waste.

The prime requisite of illumination is, as already stated, that it shall be uniform. Whatever source of light is to be used therefore a better distribution must be obtained, if economy is to be considered. Having secured this result to as great a degree as possible, the problem then becomes comparactively simple. Knowing the illuminating power of the sources to be used, the general brilliancy to be required, and the extent of space to be illuminated, the distribution of the light unit is readily determined.

The intelligent engineer will now look to the quality of the light. In this regard we can do little more at present than to provide the most economical means possible for the diffusion of the luminous rays, leaving no naked light sources visible. In case arc lamps or Welsbach burners were to be used for interior lighting, he would doubtless seek to reduce the excessive blue and violet of the former, and the yellowish green of the latter, by means of suitably tinted globes.

For securing a better distribution and diffusion of the light, advantage must be taken of the well-known properties of refraction and reflection. In diverting the upward flux into the lower hemisphere, reflection is, within certain limits, the only means possible. Regular reflectors, either of silvered glass or polished metal, have long been used for this purpose; but they have several serious defects. Glass is fragile, polished metal tarnishes, and neither produce any diffusion, but rather increase the glare. Irregular reflecting surfaces, as the so-called porcelain and white enameled metal, correct some of these defects, and give about an equal efficiency, reflecting about 80 per cent. of the incident light.

The most common method of securing diffusion, and partially correcting the distribution, is by means of globes, either roughened on the surface by sand-blasting or etching, or rendered translucent and milky in the process of manufacture, "opal," or "opaline" glass. While the diffusion produced by these means is good, the method is extravagantly wasteful. Clean ground glass will absorb 30 per cent. to 50 per cent. while opal glass absorbs from 50 per cent. to 80 per cent. of the light.

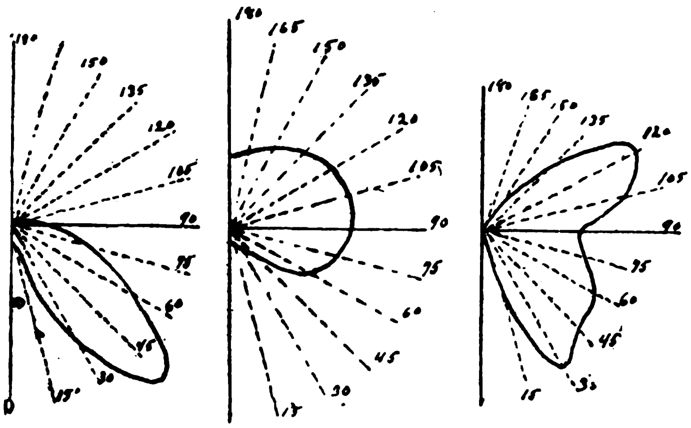

FIG. 1.—CURVES OF DISTRIBUTION.
I.—*Direct Current Arc.* II.—*Flame.* III.—*Alternating Arc.*

Besides this loss by absorption, such glass causes an additional practical loss by diverting more light into the upper hemisphere, when used with the arc light. In this case the globe itelf becomes the practical source of light, each point on the surface giving out light in all directions, outside the tangent plane. With the direct-current arc most of the light would fall on the lower half of the globe; but for the reason just given, this lower half would throw considerable light in the upper hemisphere which would otherwise continue its downward course. The higher the arc is placed in the globe, the greater the loss in this way.

On account of the serious objections to the means just described various attempts have been made to secure better results by the systematic use of refraction and total reflection. Ribbed glass was the earliest attempt in this direction, and its use is very old. Glass of this kind was used in the electric lanterns in the streets of London. Mr. Edward Atkinson has recently revived interest in the use of such glass by applying it to the windows of factories. The results were very satisfactory, the corners and spaces between the windows being much better illuminated.

The next step was the use of two such panes placed together, with the flutings crossed at right angles, suggested by Raffard in 1881. This was simplified by Trotter in 1883, by ribbing a single sheet of glass on both sides, a method which Cooper and Richardson had suggested 10 years before. The method is still quite commonly applied to lamp "shades," or globes. Seaver has brought out a globe having interior meridianal prisms, which have the effect of widening the apparent source of light. As might be expected, they show the prismatic colors at the edges of the light. Shades having similar prisms on the outside are also to be found, and produce a similar result.

An attempt has been made to apply this principle to blown glass lamp chimneys, but as the process of blowing is incapable of producing appreciable variations of thickness, it is evident that such attempt must be practically useless.

The idea of giving a special form to the ribs or flutings, so as to distribute the light according to a predetermined law, was suggested by Fresnel more than 50 years ago, and has been very highly developed for light-house purposes. Comparatively little attention, however, has been given to applying the principle to the problem of securing a better distribution for general illumination.

LITERATURE

THE COMMERCIAL ORGANIZATION OF FACTORIES.—By J. Slater Lewis. New York. Spon & Chamberlain. (Sold also by The Electrical Engineer.) Large octavo. Illus., including loose plates. 540 pages. Cloth, $12.

This is, indeed, a superb and masterly treatise, covering the entire ground suggested by its title and going into many branches of the subject that are pertinent and cognate, but which would not at once occur, even to a student of economics. The broad principles are well noted, with a quiet shrewdness that often strikes the reader as falling little short of inventive genius; and at the same time, a multitude of details are dealt with in a close, hard, practical way that evinces the most intimate acquaintance with manufacturing as done on the modern large and clean-cut style.

Mr. Lewis is not in any wise satisfied with a few chapters on running work through the shops, but deals even with the officers and the organization of the company, and has many points of information and interest at each step. He devotes serious attention, for example, to the use of reply postals, the phonograph, filing of letters, and makes some excellent comments on advertising, being in favor of the "full page" as a sure sign of enterprise, and recommending that if smaller "ads" are carried in several papers they should have a marked family likeness, rendering them readily recognizable. In fact, all the minutiae of correspondence and publicity are dealt with, and as the book is based primarily on English practice there are here, and in all the other sections, important differences to note, not at all the advantage being in our American way by any manner of means.

When we get into the factory, Mr. Lewis is perhaps at his best, and one follows the men through their daily toil, the goods, from the raw material to the finished product, in every conceivable fashion that may be considered orderly. Forms, blanks, tables, diagrams, are given at every step, and while Mr. Lewis has his preferences, his whole treatment of shop practice and methods is luminous, harmonious and soundly philosophic. Of course, it is understood that there is no Procrustean bed proposed for every manufacturer to measure himself on. Any well conducted shop has a system of its own stamped with the sagacity and experience of somebody, but there is always gain in uniformity and in studying the technique of other people who have proved successful. We imagine it to be difficult for any factory owner or manager to go through this valuable and interesting book without picking up innumerable hints, or being shown how various improvements can be made in his own well established system.

The book is beautifully printed in plain, large type on good paper, and the illustrations are excellent. The frontispiece is a colored diagram, showing by means of a "tree" the proper and natural course of business through the various channels and departments.

THE A B C OF THE X-RAYS.—By W. H. Meadowcroft. New York. The American Technical Book Co. 5 x 7½ in. 189 pp. Price, cloth, 75 cents; paper, 50 cents.

In this little work Mr. Meadowcroft has followed the same style of exposition as that pursued in his deservedly popular "A B C of Electricity." In both, nothing has been sacrificed to accuracy, with the result that those well up in electrical work as well as the layman, can read it to advantage.

The author introduces his subject with a brief sketch of the history of the Röntgen ray and then explains in succession the principles of operation as well as the details of construction of the various parts of an X-ray apparatus, including Ruhmkorff and high frequency coils, tubes, circuit-breakers, etc., all made thoroughly clear by diagram and pictorial reproductions. The chapters on manipulation and practical suggestions, as well as that on photographic plates will prove all-sufficient for the obtaining of the most satisfactory results.

The book ought to be in the hands of every one interested in X-ray work.

Vol. XXIII. NEW YORK, FEBRUARY 10, 1897. No. 458.

DO ISOLATED PLANTS PAY?

NEXT to the municipal plant question, there is perhaps no topic of more pressing interest to the owners of electric lighting properties than the future status of their holdings. Of late attempts have been made in various quarters to sound an alarm to the effect that electric central stations are doomed, and but a few weeks ago we had occasion to notice and comment upon an article in which this assumption was taken as the text. At that time we showed,—as far as the limits of a brief editorial could do so—some of the errors into which the writer referred to had fallen, and the serious omissions, all of which made the conclusions arrived at of doubtful, if not of completely negative, value. That the position taken by us in this matter was justified is, we are glad to say, confirmed by the statements which appear in an exceedingly interesting article contributed by Mr. R. S. Hale to the "Engineering Magazine" for February. Mr. Hale defines his position as a critic at once, by stating that for the last three years his work has been chiefly in the line of analyzing records and tests in general engineering, but chiefly in electric station work for the Boston Edison Company, in order to find out why theoretical and practical results should be so different. Here certainly was an equipment for work which perhaps few investigators and engineering accountants have at their command.

Mr. Hale first points out an arithmetical error made by the advocate of the isolated plant, but we pass that over and come to the question of the cost of coal for the plant under discussion, which is capable of supplying 2,500 lamp hours per day, and requiring the generation of 186½ kilowatt hours. The original writer assumed that by utilizing part of the exhaust steam for heating, the coal consumption could be brought down to 5 lbs. of coal per horse-power per hour. This figure is very properly considered by Mr. Hale to be absurdly low for a plant of the size under discussion, since it would have a single expansion non-condensing engine of small size for which there are no exact records of output in coal consumption of a plant of the size given. But he refers to the report of the Committee on Data of the National Electric Light Association for May, 1896, in which it is shown that the average consumption of coal per horse-power hour for a large number of central stations is 12.2 lbs. Even assuming that one-half of the heat contained in coal would be employed for heating during six winter months the average would still be 6.1 lbs. of coal as the average per horse-power hour chargeable to electricity, without considering the extra cost due to the fact that an isolated plant is smaller and worse managed than a central station using similar engines.

Mr. Hale then takes up the cost of labor, which the previous writer had taken at $2.50 per day, and which proves to be about as low in proportion to the actual cost as is the five pounds of coal per h. p. hour. As Mr. Hale points out, a responsible engineer who can take charge of the plant, run the engine,, take care of dynamos and look after storage batteries, and be satisfied with $2.50 a day, would be hard to find. If storage batteries are not used, then, in order to give the same quality of service as that supplied by the central station, two engineers would of course be required to be on duty twelve hours a day each. In addition, though the labor of the fireman during the winter is, of course, chargeable against steam heat, during the summer his wages must be an extra expense.

Mr. Hale then takes up the question of the relative investments required for central station and isolated plants of like capacity, and the items of depreciation, taxes, insurance, interest, etc. Without following him through all these details, we may state briefly that his conclusions are that the isolated plant is very seldom charged with any part of its share of the taxes, insurance, depreciation or interest, and that large portions of the management, accounting, repairs, labor and miscellaneous expenses of an isolated plant are also charged against other accounts. He finds, however, that the first cost of an isolated plant is actually less than that of a central station only in items of boilers and electric street conductors, the isolated plant being more expensive in the first cost for engines, dynamos, real estate, and other capital accounts.

As a matter of fact a comparison of the real expense of an isolated plant with those of a central station shows that not only is the total first cost practically as much as for the central station in proportion to the current supplied, but that if all the expenses are included, the cost of operation of an isolated plant is far greater than that of a central station. We cannot help referring to what appears to us a very apt remark in Mr. Hale's résumé, namely, that it is cheaper for the real estate man, the hotel keeper, or the dry goods merchant to devote his brains and intelligence to making money in his own field, where he is an expert, than to waste his time on a small electric plant, provided he can get station current at a fair and moderate price. No matter how skillfully he may run his isolated plant, he generally will lose money or—which comes to the same thing—not make as much money as he would have made had he employed his time, his capital and his brains where they are most effective. Mr. Hale has evidently treated the subject in a thoroughly unbiased manner, and we are certain that his conclusions will carry due weight among those who are now, or are contemplating, operating isolated plants. As a matter of fact there are few isloated plants of any size installed nowadays without making provision on the switchboard for connection with the street mains, and although it may take some time to bring about such a result we are pretty well convinced that sooner or later the street connection switch will remain permanently closed. There was a time, we are sorry to say, when central stations objected to furnish current to isolated plants, and possibly their early refusal may have determined not a few owners of buildings to declare their independence; but with the more liberal views adopted by the companies on this point during recent years, owners of buildings have been placed in a better frame of mind and are willing to listen to the representations of central station companies, looking towards the entire supply of current from outside.

ALUMINUM.

WHEN the production of aluminum on a commercial scale became an accomplished fact some years ago, it was predicted that this metal would in time displace others, which had theretofore held their own in the arts from time immemorial; but until recently the high price of aluminum has always militated against its use for many purposes. That we are approaching the realization of the predictions, however, is evident, and it is now only a question of time when we shall see aluminum freely substituted for brass, copper, iron and steel in many situations. What has undoubtedly hastened the substitution is the continued reduction in the price of aluminum, and the recent cut made a few weeks ago will further accelerate the process. Sheet aluminum has been reduced in price from ten cents a pound in the heavier gauges to twenty cents a pound in the lighter. Thus No. 20 gauge has been reduced from 62 cents to 52 cents a pound, and No. 30 gauge from 93 cents to 73 cents a pound. When one considers that counting the weight of aluminum as equal to 1, sheet copper is 3.3; brass, 3.1 and steel 2.9; it follows that taking into account the difference in the weight, aluminum is now brought almost directly in competition with sheet brass, while, as a matter of fact at the present time it is actually cheaper than nickeled brass. As to the status of aluminum, in the elctrical industries more particularly, and its probable use as a conductor, the article by Mr. C. C. Burr, which appeared in our last issue, is deserving of more than passing attention. As Mr. Burr shows, the relative conductivity of copper and aluminum is as 100 to 63, but owing to the difference in weight, which is in the ratio of 1 to 3.3 in favor of aluminum, weight for weight, the latter has a conductivity relative to copper as 208 to 200. This may make it a determining factor in using it as a conductor, as was the case in the equipment of the Pittsburg Reduction Company, at Niagara Falls. This is a fact which will probably be borne in mind by electrical engineers, in special work. We believe that with the further reductions which will probably be brought about in the price of aluminum, this metal will find a still greater variety of applications than it enjoys at the present day.

TELEGRAPHIC HEROES.

THE dinner of the Magnetic Club in this city last week served as a formal acceptance on the part of the telegraphic and electrical fraternity of the gracious though tardy act of Congress in honoring the worth and valor of the gallant old U. S. Military Telegraph Corps. The effort to secure this recognition has run through many years and has been the more creditable for the reason that it was not a mere hunt for pensions, but a simple, earnest insistence on the fact that the noble work done by the telegraph boys in the Civil War should at least be signalized by the country for whose preservation it did so much. In a sense, the bill signed by President Cleveland constitutes a distinct or separate order of valor and good service. So far as we are aware, it is the first action of the kind anywhere, on service of this nature; and, perhaps, with the near coming of a time of perpetual peace, there may never be another. To the handful of two hundred survivors of the original twelve hundred, we are delighted to be able to extend our congratulations. Telegraphy has been the mother country of all the other electrical arts, and such examples as these heroes presented are a precious common heritage for us all.

Steps have been taken from time to time to place all the skill of electricians at the disposal of the government in time of national peril, just as all the resources of the telegraph were in 1861. But we confess our deep disappointment at the result. The Naval Reserve is a fine body, but if electrical men think they are getting into condition for helping their country materially by tumbling around in clumsy dingies and superannuated training brigs we must very respectfully differ from them. What is wanted is a special corps that can protect by electric mine and torpedo our whole coast line and harborage and do for the Government that which in this respect the U. S. Military Telegraph Corps did for it on land in other times of need. Here is genuine opportunity for youthful electrical patriotism, so far as the frontiers on the sea are concerned.

MR. TESLA AS A BUG KILLER.

THERE can be no doubt as to the invasion of the domain of agriculture by electricity. Last week we noted the results obtained on a farm in Germany, and hardly a week goes by without its news of farmers using the telephone in their operations, experiments at agricultural stations with all kinds of current in stimulating seeds and plants, or the use of power from lighting or trolley circuits in running farm machinery. Indeed, it may be said to be doubtful whether the factory or the farm is to be the new scene of electricity's next triumphs.

It will be remembered that not long ago, Mr. Tesla suggested that part of the energy of powers like that of Niagara might be applied to furnishing nitrogenous elements to the soil, so that better crops could be secured. This may explain why a Mr. S. S. Harvey in the South wrote to him asking if electricity could not be used in a general pervasive way to kill off the bugs that are such a pest in orchards and vineyards. Mr. Tesla, with wonted courtesy, admitted the importance of the subject and said in response to the inquiry: "It is sure that we can destroy these detrimental insects in certain ways by the help of electricity, but to what extent the trees would be affected by the application of these means I do not know, and it could only be settled by a series of experiments. I have some ideas on the subject, and think that an apparatus for experimentation could be produced in a short time. I am resolved to think over the matter in the hope to arrive at some tangible result."

We have no doubt that to some people the idea of a notable electrical inventor devoting his time to devising bug traps and "sure deaths" smacks rather of the grotesque and ridiculous; but in reality Mr. Tesla could not undertake anything of more real and practical value. When one stops to consider how famine, ruin and devastation afflict the human race because of such pests as the locust, phylloxera, army worm and potato bug, it is evident there is work to do of real vital importance to a great many people.

ROENTGEN TUBE CONTROL.

THE enthusiasm with which the Röntgen ray has been taken up, especially in the United States, has led to the design of excellent apparatus for this work at a reasonable cost. It has thus placed in the hands of the scientist and surgeon a powerful instrument of research, and given the amateur a new and attractive instrument for his diversion. But, perfect as the mechanical and electrical part of such apparatus has been made, the weak spot in the combination is still the tube, which has to be constantly coaxed, as it were, to bring out the desired form of rays. The variability in the working of the Röntgen ray tubes is accompanied by and has been ascribed to the change in the vacuum, and various devices have been employed to overcome it; such as heating the tube, and in the case of the Bowdoin tube, coating the interior surface with a fluorescent material. It would seem, however, that another effective device is now available for keeping tubes in normal action, due to a discovery described by Mr. Max Osterberg on another page. The simple device there described ought to go far towards making X-ray work more reliable and expeditious than it has been in the past.

ONE OR TWO ALLEGED ELECTRIC FIRES.

IT is one of the present propensities of the average reporter to attribute every fire to an electric wire. During the past week, two such instances have occurred. In New York City on Feb. 1, the drapery in a ballroom caught fire, and was at once attributed to electricity without any evidence, as there were no wires adjacent to the stuff. The "Evening Post" says: "Somebody turned in an alarm and the fire engines responded. When they arrived they found the orchestra still playing and the fire out. It was said that the fire started from a defective electric wire, but it is also believed that some one of the young men tossed a lighted cigarette into the folds of the drapery. The damage amounted to about $50." The other instance was that of the Pennsylvania capitol at Harrisburg, to which damage to the extent of $500,000 was done, practically destroying the edifice. Every report that went out at first said that the fire was due to a defective wire, but there is absolutely not a single proof of this. The Philadelphia "Ledger" says: "The origin of the fire is a mystery. It was said in the afternoon that it was caused by an electrc light wire which had no insulation. The officers of the Harrisburg Electric Light Company declared that it could not have originated in that way.

"'The building,' one of them said, 'was re-wired several years ago at the time the insurance was placed. The wiring was installed under the rules and regulations of the Board of Underwriters and was carefully inspected and approved. The odor of smoke was apparent to a number of the Senators and employés from one to two hours before the fire was discovered. Had it been caused by contact of wires the fire would have been apparent in a very short time.

"'The theory which has the most foundation in fact, is that it originated from the open hearth fire in the Lieutenant Governor's room, and burned under the floor along the joists to the hall partition, where it was discovered. This hearth was ordered rebuilt last summer by Senate Librarian. Miller, as he deemed it unsafe at that time. The accumulation of the dust of many years and inflammable particles made the progress of the fire under the floor an easy matter.'" From all the other evidence, this seems to be the correct version, but as to electricity, no evidence whatever has been brought forward implicating it.

THE signing of the ordinance in Chicago for some sixty miles of underground conduit railway marks another big advance of that system. The recent reports from Washington show that the conduit roads there ran well through the recent heavy snow and rain storms, and it was open to general observation that in this city the Lenox avenue line and that which Mr. Law is operating further out were both doing good work all through the time of blizzard. What we would like to see, however, is a fair stretch of sealed conduit in operation. The snow packs in the open conduits in a remarkable way, and it takes an awful lot of power to pull through. A sealed conduit, to say nothing of other advantages, is at least free from that strain and drain of current.

ELECTRIC TRANSPORTATION

TROLLEY ON A STEAM RAILROAD IN CALIFORNIA.

A VERY interesting adaptation of the electric motor to the steam car has recently been made on a railroad in California. The California Railway Co. operates a short line of road some three miles in length, which runs from the junction of the Southern Pacific Railroad, to Leona Heights, passing on the way Mills Seminary, the California equivalent of Vassar College. The road serves Alameda and Fruitvale, which are both located just across San Francisco Bay opposite San Francisco itself.

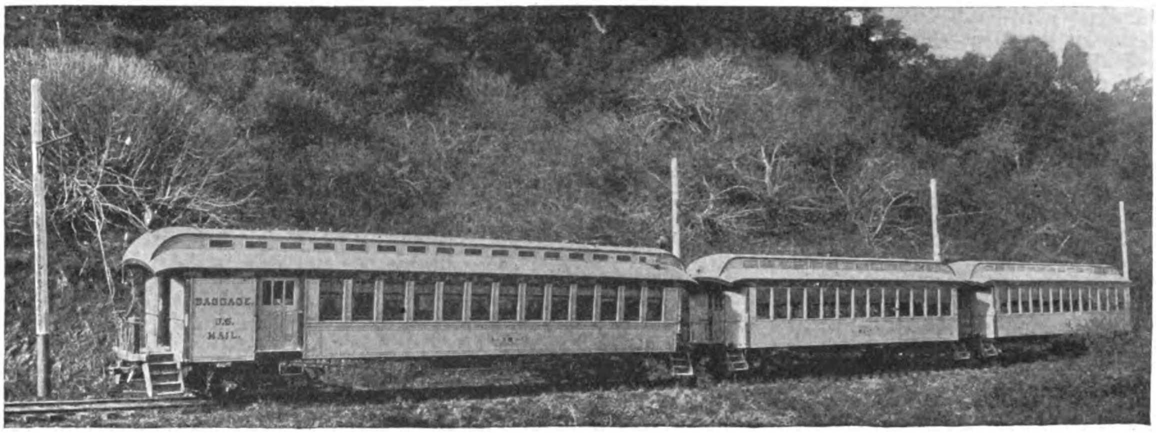

FIG. 1.—THE TROLLEY IN STEAM RAILROAD TRAFFIC, CALIFORNIA.

The cars used are standard steam railroad cars. The motor cars of the trains, of which one is shown run out, for the purpose of being photographed, are composite baggage and passenger cars. Motor car No. 11 is vestibuled at each end and carries on each hood an electric headlight. It takes current from an overhead wire by two trolleys, one of which only is in contact during operation. Each motor car is fitted with an automatic air pump to operate the brakes and the chime whistles, of which there are two, one on each hood.

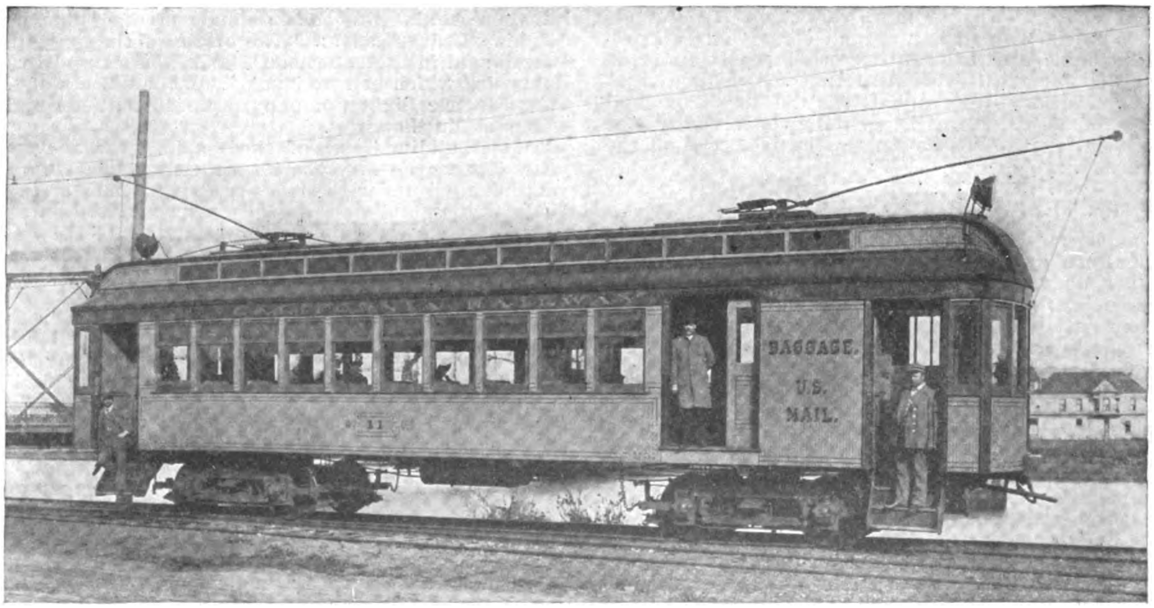

FIG. 2.—THE TROLLEY IN STEAM RAILROAD TRAFFIC, CALIFORNIA.

The motor equipments consist of four G. E. 1,000 motors, two mounted upon each truck, made by the General Electric Company. The controllers are of the K type and are provided, of course, with a magnetic blow-out. Each car is provided with automatic circuit breakers and resistances, and the interior by incandescent lamps in groups of three.

Motor car No. 21, which is shown coupled to its train, is also a composite car and is similarly equipped so far as its electrical apparatus is concerned. It is not vestibuled, however, and was one of the first to receive its electrical equipment.

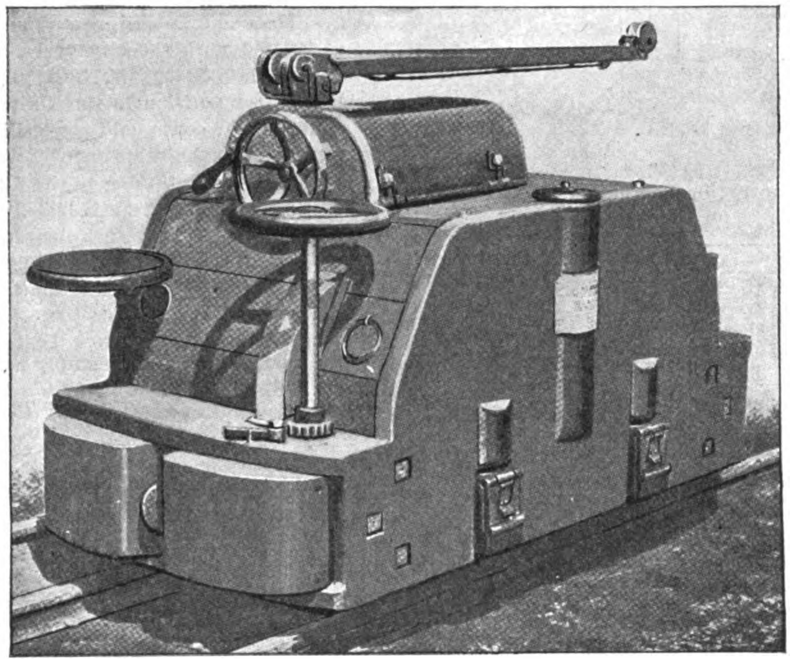
The track is of standard steam railroad construction bonded for the return. The overhead line is suspended from iron brackets swung from round poles for part of the way; for the balance of the distance it is suspended from span wires. The general character of the equipment of this road is similar to that in operation on the New York, New Haven and Hartford, with the exception of the motors, and it will be recalled that the cars of this latter line and their equipment served as models, both in the design of the car itself and the arrangements of the motors, for the locomotive designed by the late D. L. Barnes.

The General Electric Company, which carried out the equipment of the California Railway Company, through its Pacific coast office, will equip another locomotive for use on the Alameda and Fruitvale line, using, however, two or four G. E. 2,000 motors instead of G. E. 1,000 motors as on the other cars.

THE THOFEHRN ELECTRIC MINE LOCOMOTIVE.

A VERY compact and powerful little electric locomotive for use in mines and workshops was some time ago suggested by Mr. Hermann Thofehrn, the well-known consulting engineer and expert in electrolysis. This locomotive represents some excellent features; its construction is shown in the accompanying illustration, taken from two now employed in the refinery of the Anaconda Copper Mining Company.

These locomotives, says the "Engineering and Mining Journal," were installed some three years ago for conveying the copper from the railroad cars to and from the different charging points and for transporting the refinery slimes from the tanks to the silver mill. In this way they handle a large quantity of material every day without any trouble and to the entire satisfaction of the company. The General Electric Company has recently constructed two more locomotives of the same type with a draw-bar pull of 1,000 lbs., to be operated at 120 volts. These locomotives are now at work in the mines of the Anaconda Copper Mining Company at Anaconda, Mont.



THOFEHRN ELECTRIC LOCOMOTIVE

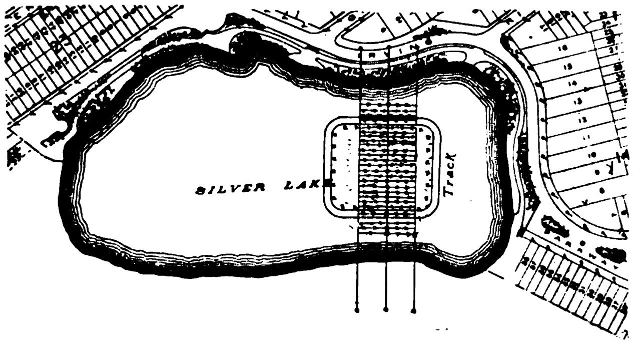
The locomotive is less than 6 feet in length, is built entirely of iron, and can pass through a tunnel 4 feet high by 3 feet wide. It can be operated at small expense, as it does not require a special electric plant to generate the power, an ordinary incandescent light plant being able to furnish the needed current. The low voltage makes the locomotive entirely inoffensive externally, while on the other hand the sensation felt when touching the contacts or the trolley wire is sufficiently disagreeable to call for caution. The danger of fire in wet mines where this locomotive may be employed is also very small in consequence of the low voltage.. The gauge of these locomotives is 20 inch and the wheels are 14 inch diameter. Besides passing through a tunnel 4 x 3 feet, these engines can run over a curve of 8 feet radius, the wheel-base being only 22 inch.

DEVELOPING TROLLEY TRAFFIC BY A SKATING CARNIVAL.

AN illustration of what can be done in fostering special travel by means of ordinary resources has just been given by the Staten Island Electric Railway Company, through the shrewdness of its general manager, Mr. A. D. Chandler, who as an old journalist is quick to see the possibilities of every passing hour and make the most of them. On the outskirts of Brighton is a beautiful spot called Brighton Heights, which is being built up by the New York and Staten Island Land Co., into a very handsome suburb. The heart of this district is Silver Lake, a lovely little sheet of water hitherto quite unknown to most New Yorkers. Trolley traffic in that undeveloped region is necessarily very light in winter, but the sharp frost early in January set Mr. Chandler thinking, and the result was that all of a sudden Silver Lake loomed up with a celebrity that became national among the skating fraternity. Over the lake, which lies a few hundred yards from the trolley line along the Richmond turnpike, were strung three strands of ⅜-inch wire, giving a total 600-foot span, anchored each end. To this was run a circuit from the trolley line and between the two sides were stretched and suspended 25 cross spans of copper wire each of which carried 5 incandescent lamps, so as to take up the 500 volts of the trolley line. These lamps were red, white and blue intermixed, and made a bewitchingly pretty canopy when swinging galley in the night air over the glistening ice and the merry throngs of skaters. Under this canopy of lamps there ran, as shown in one of the cuts, a race track of one-quarter mile lap, with the corners curved or blunted so as to make them easy for the competitors. All the races took place at night, under the auspices of the Amateur Skating Association, and to define the line of track 24 gasoline torches accentuated its inner edge.

NIGHT SCENE, SILVER LAKE, STATEN ISLAND.
Showing Lines of Incandescent Lamps Run from Trolley Circuit.

The whole thing was tremendously successful, and the lake will draw crowds all through winter while skating lasts, besides making the region known favorably for miles around. Out of nothing, Mr. Chandler built up a traffic of 30,000 people in the 20 days from Jan. 10 to Feb. 1. In order to lengthen out the dispersal of the crowds, there were novel fireworks after the races, and the band continued to play until but few of the visitors were left. Altogether, the enterprise has been a great hit and has elicited the attention of street railway managers all over the country; besides filling many columns in the daily newspapers.



ELECTRICALLY ILLUMINATED ICE RACE TRACK, SILVER LAKE, STATEN ISLAND.

TELEPHONY AND TELEGRAPHY

THERE ARE SOLID TELEPHONE COMPANIES—AND OTHERS.

SOME time last fall a concern started in business in this city, says the Youngstown "Telegram," under the name of the Central Telephone Company. The men in the company were from Alliance, and they located their plant over the Hub Bicycle Company's room on Central square. The business of the company was to make telephones and although they started in in a modest way, they expected to grow. The transactions of the company were all square, and they entered into correspondence with a number of concerns to secure quotations on different articles which they used in the manufacture of telephones. Among these was a Philadelphia electrical supply company which does a large business throughout the country. Quotations were asked on generators.

The Philadelphia firm looked up the standing of the Youngstown firm in Dun's, and found the Central Union Telephone Company rated at $7,500,000. That was enough. Not stopping for the slow vehicle of correspondence to bring the order for the large number of generators which a company rated at $7,500,000 would use, a member of the firm came to the city with visions of mammoth orders before him.

When he got here he at once found his way to the office of the Central Union Telephone Company. He met Manager Johnson.

"I have come," he explained, after handing his card to the manager, "to give you quotations on generators."

"Well, you'll have to go to our Columbus office, the headquarters for the State," responded Manager Johnson.

"Have to what?" asked the Philadelphia man.

"Go to Columbus. They do all of the buying for the State."

"But didn't you write to us for prices on generators?" asked the Philadelphia man.

"Why, no," said the manager.

"Isn't this the Central Union Telephone Company?"

"Yes."

"Well, I have——" here the Philadelphia man took out of his pocket a letter and found that the concern he was to deal with was the Central Telephone Company. Explanations followed and the Philadelphian took his way to the office of the Central Telephone Company, which he found closed. The business of manufacturing telephones had not been prosperous and the Alliance men had wound up their affairs before his arrival.

The Philadelphia man returned home minus the order from the Bell telephone syndicate, which he had so confidently expected to secure.

WEST INDIAN CABLES.

A special dispatch from London, of February 1, says: The Secretary of State for the Colonies, Joseph Chamberlain, in the House of Commons to-day, replying to a question relative to the construction of a cable under British control to the West Indies, said that negotiations on the subject were proceeding. He was unable to say when it would be completed, and he admitted that he was aware that a French-American company had recently laid a cable which would compete with the proposed British cable.

CABLE OVERCHARGES IN SOUTH AMERICA.

A SPECIAL cable dispatch from Buenos Ayres, of January 31, says: The Western and Brazilian Telegraph Company, an English concern, which has a monopoly of the telegraphic communication on the coast of Brazil until 1913, is connected with the city of Buenos Ayres by the lines of the River Plate Telegraph Company of Montevideo. In order to harass competition in the United States and Europe an overcharge of 57 cents gold a word beyond Buenos Ayres has been imposed on telegrams sent by way of Galveston to Brazil since 1892. Representations to the different governments concerned produced no effect until last June, when this government ordered the River Plate Telegraph Company to stop collecting the overcharge in Argentine territory. Protests and proposals for an arrangement of the matter followed, all tending to elude the jurisdicton of Argentina. Last October the Argentine government gave the River Plate Telegraph Company twenty-four hours' notice to comply with its decrees. The company replied, stating that it had obeyed and always would obey the orders of the government. This has since been found to be false, because on the occasion of the reduction of rates in January the overcharge on messages to Brazil figured along with the new tariffs submitted for approval, according to law. The government sent a representative to the office of the River Plate Telegraph Company to prove that a violation of its decrees was being insisted upon, and at 3 o'clock yesterday afternoon the government stopped the service here of that company in consequence of the evidence of insubordination. Since then the River Plate Telegraph Company has inquired of the government on what terms the reopening of its office would be permitted, and the government has replied that only on unconditional surrender, without any reserve expressed or implied, will the company be allowed to resume business. This the company has failed to agree to, and consequently its office here will remain closed until such time as it sees fit to comply with the order of the government to make the tariff uniform, charging all the public alike and stopping the discriminating rate hitherto imposed on telegrams by way of Galveston.

ERIE TELOPHONE.

The Erie Telephone directors have declared the regular quarterly dividend of 1 per cent., payable February 15.

The annual report, to be published early in April, will show an increase of 2,798 in the number of subscribers during the year, making the total number connected December 31, 1896, 21,389, against 18,591 December 31, 1895, and 16, 174 December 31, 1894.

The report also will give detailed statistics concerning the wire mileage, showing a gratifying growth. The actual wire mileage now including the long distance toll lines is 42,000 miles. The company's largest single line in the Northwest now is 750 miles and in the Southwest 650 miles.

BELL TELEPHONE OUTPUT.

The Bell Telephone statement, issued for the month ended January 20, shows an increase of 4,197 instruments over the 3,839 net output for the previous month. For the first six months of 1896 the net output averaged 11,819; for the last six months, 4,399. The statement for January 20, 1897, shows 73 instruments under the 8,109 average monthly output for 1896.

COMMENT ON THE HAWAIIAN CABLE.

The Hawaiian cable scheme or schemes again occupied the attention of the House committee this week. Two rival companies are seeking a government charter with incidental subsidy. Each, according to itself, is a pure and patriotic and wholly American organization; each, according to the other, is but a cat's paw of England. What with preventing Nicaraguan canals from being built and covering the Pacific with a network of "military" submarine cables, British gold would appear to be having an unusually busy winter. What the poor Hawaiians want is, of course, altogether a secondary consideration. They exist only to be annexed and have cables landed on their territory. It may be worth saying, however, merely as a matter of curiosity, that they are heartily opposed to any such cable monopoly as is being urged at Washington. The Spalding concession, which will lapse in a month or two, the Hawaiian government refused to extend or amplify when ex-Secretary Foster was sent to the islands in November to secure a new contract. A rather tempting bribe of $375,000 cash down was dangled before President Dole, but the Chief Justice told him he had no right to make an exclusive contract, the business and commercial interests of Honolulu pronounced strongly against the scheme, and Mr. Foster had to come away empty-handed. All this will, of course, be regarded as wholly irrelevant at Washington, where the process of voting away the lands and franchises of other nations is one of the chief occupations of some of our leading statesmen and lobbyists.—New York "Evening Post."

LETTERS TO THE EDITOR

PROF. ANTHONY'S METHOD OF MOTOR SPEED CONTROL.

REFERRING to Mr. Blood's communication, page 146, of your issue of February 3, I have been unable to find the German and French patents to which he refers, but upon examining the catalogue in which Mr. Blood claims that motors embodying the idea are listed, I find that four pole machines are among those listed as variable speed motors, and, as my method of control is not practically applicable to four-pole machines, but only to machines having an odd number of pairs of poles, it is evident that the method of speed control employed in the motors catalogued is not the method that I described.

I have looked through the patents to Wightman and the only one I find that describes a method of control bearing any resemblance to mine, is No. 542,667, of July 16, 1895, a patent with which I was before entirely familiar, and in which the resemblance is superficial only. In reality his method and mine are totally unlike in principle and results.

His method necessitates the use of a multiple path or "parallel" multipolar armature winding. Mine requires a multipolar armature winding of the two-path or "series" type. His method gives the high speed for the normal multipolar working of the machine. Mine gives the slowest speed under the same conditions. In his method applied to a four-pole machine, the change of speed is obtained by reversing one pair of poles and at the same time, by means of the controlling switch, disconnecting from the circuit one pair of (opposite) brushes and connecting the two remaining brushes, which are now of opposite polarity to opposite sides of the circuit. In other words changing the machine from a four-pole to a two-pole machine.

In my method the change of speed is effected by changes in the field only, no change being made in armature connections. Moreover, my method permits of every gradation of speed from the highest to the lowest.

Before applying for a patent I had a search made at the Patent Office, which disclosed nothing really like mine, although several patents were found which seemed to bear some resemblance, but which upon examination proved to relate to bipolar machines having each pole in two or more sections, so as to look in the drawings like multipolar machines. My application passed through the Patent Office without any question as to the novelty of the method, without a single citation against or objection to any of the claims.

In relation to my explanation of sparking, it is a fact that, when the speed of a motor is increased by weakening the field, troublesome sparking sooner or later occurs.

No one doubts that the weakening of the field is the cause. But to say that a field is weak is the same as saying that some of its lines have disappeared. Moreover, it is a fact that as a field is weakened the density around the corners and angles diminishes, in general, more rapidly than the average density. In a motor this disappearance of some of the pole corner lines, leaves the lines due to the armature current free to act to produce sparking.

Mr. Blood may, if it seems plainer to him, call this "distortion into the region of commutation," but the distortion occurs because one of the components, the lines of the pole fringe due to the field, have, partially at least, disappeared.

WM. A. ANTHONY.

New York, February 4, 1897.

THE KELLY STATIC INSTRUMENT FOR DETECTING GROUNDS.

At the last meeting of the Northwestern Electrical Association, Mr. H. C. Wirt, of the General Electric Company, recommended the use of a static instrument as a means of detecting grounds and stated that such an instrument would be on the market in six weeks. Allow me to call your attention to the fact that such an instrument has been on the market for two years and that its use is fully covered by United States patent, No. 554,275, dated February 11, 1896, granted to me.

JOHN F. KELLY,
Stanley Electric Manufacturing Co.

Pittsfield, Mass., February 1, 1897.

PATENTS ON COUNTER ELECTROMOTIVE FORCE REGULATION.

REGRETTING that I feel it necessary to trespass further upon your valuable space, I think it proper that the facts relative to the counter electromotive force regulation situation should be more fully stated in view of Mr. H. Ward Leonard's reply on page 34 of your issue of January 6, to my criticism of your article implying that he stands as the inventor of the broad invention.

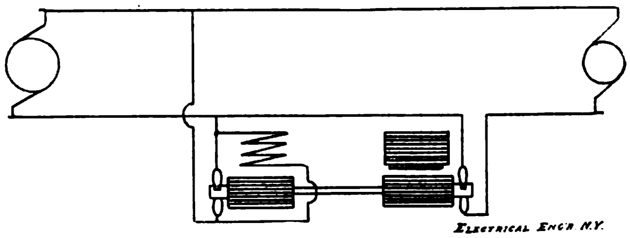
Mr. Leonard had three interferences with me, two on broad issues and one specific. No testimony was taken in any of them. The issues of the broad interferences read:

> The method of controlling motors which consists in supplying to the motor a current of electricity, producing by magnetic induction in the circuit between the source of supply and motor a varying magentically induced counter electromotive force independently of that of the motor, and opposing the current of electricity supplied to the motor by varying the magnetically induced counter electromotive force.

This was one of some fifty of my claims. This was interference No. 16836. Mr. Leonard was, in effect, defeated in this, as it was adjudged that he had no right to make the claim. It is still in my application. The next interference had the following issue:

> In combination with an electric motor, a counter electromotive force regulator consisting of a second dynamo-electric machine whose armature is in series with the motor to be regulated, and independent means for varying the counter electromotive force of said second dynamo-electric machine.

This was interference No. 16837, and besides including Mr. Leonard, it included Wheeler, Bancroft, Lundell, Wightman, Burke, Blauvelt and Woods. On motion to dissolve it brought by Mr. Leonard, I alone opposed the motion and insisted upon, as my right, the patent for it. The rest relinquished their claim to it. When a man voluntarily pulls down the edifice with his own destruction it needs no argument to show where he stands, for that shows in his fear of defeat he attempts to destroy his adversary with his own suicide.



ELECTRICAL ENG'R N.Y.

The third interference, No. 16838, reads:

> In combination with an electric motor, a counter electromotive force regulator, consisting of a dyna-motor, whose motor armature is in shunt with the line, and whose generator armature is in shunt to the line and in series with the motor to be regulated.

This interference was not contested, and so far as Mr. Leonard's construction was concerned was fully anticipated, among others, by German patent, No. 59494, of 1890, to Anspach, which shows the above drawing.

No testimony was taken in any of the interferences. This particular interference, No. 16,838, was decided in favor of Leonard on the record before the Patent Office discovered its error, and the judgment is to be vacated. This is the so-called interference Mr. Leonard refers to as having defeated me.

I have no desire or wish to detract from the work of others, but I strenuously object to them clothing themselves with so-called honors to which they have no right and which they attempt to hold at my expense. I was somewhat amused at Mr. Leonard's suggestion to "discuss the results" with me "after the Patent Office has issued a patent to the first inventor," as the time for discussion or contest, in my opinion, is before the decision as to who is the first inventor.

In "The Electrical World", on pages 67 and 68, of January 9, will be found information as to the art and its bearing upon the Leonard patent of December 8, 1896. Mr. Leonard's personal attack upon me for standing up for my rights does not strengthen his position. He so sarcastically refers to my antedating a reference as a means of establishing my right, yet in his reply to me in "The Electrical World," page 68, he there says he himself resorted to that practice in securing his patent. His words are, "my date of conception enabled me to antedate the references." In my case it was "reduction to practice" and not "conception" merely. The public are interested in facts, and are entitled to the truth where their position in the future is likely to be affected.

R. M. HUNTER.

Philadelphia, Pa.

AMERICAN BOOKS AND ENGLISH REVIEWERS.

The timely letter of Prof. Trowbridge, quoted in your issue of January 13, calls to mind a notice in an English electrical periodical, of Prof. J. J. Thomson's book, which relates almost exclusively to his own researches, and to his inferences and theories. This admirable treatise, which I have known to be cited by the Patent Office as an authority, was caused to appear defective, because Prof. Thomson had omitted to mention certain experiments of others. This letter is written partly in favor of the British reviewers, for in this instance, it was an English author, and not an American whose book lacked irrelevant material. In another instance, a certain book was alleged to contain too much.

The formula employed by one or two English editors, in reviewing, seems to be one in which the equation is to be satisfied by showing that a book contains too much or too little.

EDWARD P. THOMPSON.

New York, January 18, 1897.

NEWS AND NOTES.

THE NEW HAVEN STEAM RAILROAD TO COMPETE FOR LIGHTING.

A high officer connected with the New Haven Railroad Company says that a part of the plan in the operation of the electric power house at Berlin is the supply of light at New Britain in competiton with the existing local company. As the local trolley companies in a number of Connecticut cities operate plants for lighting also, the competition in electric lighting seems to be a phase of the warfare of the trolley and steam companies as soon as the latter adopt electrical equipment at competing points. It will serve to make the lighting and street railway companies allies and common foes to the Consolidated.

CHEAP POWER FOR EAU CLAIRE, WIS.

H. M. Byllesby of St. Paul, Arthur S. Huey, of Minneapolis, David Douglas of Eau Claire, and others, have asked the city council for a franchise to develop the water power on the Eau Claire River and for the erection of a power house for furnishing light and power. The gentlemen named have an option on the power and all necessary lands now owned by the Northwestern Lumber Company. The enterprise involves an investment of about $300,000.

PROF. GALILEO FERRARIS, the distinguished Italian electrician and member of the Italian Senate, is reported dead, by a special cable despatch received Monday.

THE NEWARK (N. J.) TELEPHONE COMPANY started to do an independent opposition telephone service, had a lively meeting last week, when a lot of stockholders insisted on asking questions, to which apparently they got few satisfactory answers. J. M. Gwinnell was elected president; S. Klotz, treasurer, and G. H. Atkinson, secretary. The company's plant is still incomplete, but is mortgaged with the franchise for $300,000.

MISCELLANEOUS

DEAD WIRE ON ARMATURES.

BY RICHARD PFUND.

WHILE looking over some old volumes of The Electrical Engineer the writer came across two articles by Prof. Anthony[1] and Mr. Carl Hering[2] on the so-called "dead" wire on dynamo armatures and that on armatures of the Gramme type in particular.

Prof. Anthony claims that the wire on the inside and ends is not dead because the e. m. f. developed in the coils of wire or an armature is determined by the rate at which lines of force are taken into or excluded from the area enclosed by the wire. Mr. Hering says that an e. m. f. is generated only in that part of the wire which cuts across the lines of force and that the wire on the inside of a ring is dead because, being shielded by the iron of the ring, it does not cut any lines of force, therefore develops no e. m. f. and simply acts as a conductor. He backs up this statement with a diagram, Fig. 1, showing an experiment in which brushes were applied at opposite ends of a wire on the outside surface and on the inside of a Gramme ring. The wire on the face gave a current in the proper direction, but no current whatever could be detected in the wire on the inside until the field was made very intense so as to oversaturate the core of the armature, thus causing some lines of force to leak through the air space in the inside of the ring. In this case the current induced in the inside wire was in the reverse direction to that induced in the wire on the face and tended to neutralize it, etc.

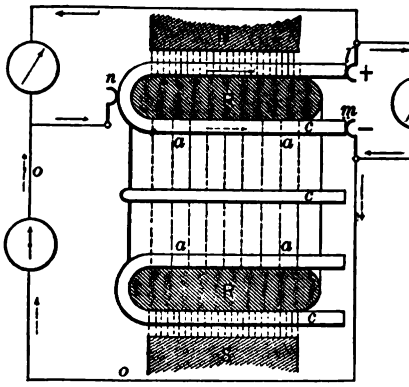


FIG. 1.

The writer thinks that there is another way of looking at this matter and that there may be an entirely different reason for the wire on the inside being dead or not as active in developing e. m. f. as that on the outside. Also that the larger the diameter of the ring, and the nearer the cross section of the ring corresponds to the carrying capacity for lines of force with reference to the total number generated by the field, the more active the wire on the inside becomes; but in no case can it be entirely equal to the wire on the outside.

Consider first Fig. 2. If lines of force are suddenly shot over the wire A in the direction shown, the current induced will be in a direction away from the observer. If the lines of force travel under the wire in the same direction as before, the current induced will be in the opposite direction, or towards the observer. Now if the wire is placed in the position shown in Fig. 3 and lines of force are shot across as before, no current, or rather no e. m. f., will be developed, because as many lines go over as go under the wire, each stream neutralizing the effect of the other.

Now consider Fig. 4. Applying the same reasoning as above, e. m. f. will be induced in the wire at the top and bottom of the ring, but none, or nearly none, in the wire on the inside at the top of the ring, because the same number of lines travel past its under side at A as go over the top at B. Furthermore no e. m. f. will be induced in the inside wire at the bottom of the ring, because as many lines go over it at B as under it at A. The two streams in each case neutralizing each other.

---

[1] Elec. Eng'r. February, 1887.

[2] Elec. Eng'r. May, 1887.

Of course the distance from the wire between the two streams of lines would make considerable difference were there no leakage across the inside of the ring and through the shaft. As such leakage actually exists and is very often considerable it appears quite reasonable to assume that it makes up, or nearly so, for the difference in distance referred to above.

The fact that Mr. Hering obtained a current in the opposite direction in the wire on the inside to that on the outside when he oversaturated the ring was no doubt due to the excess of the total number of lines passing the under side of the wire through bottom of ring and air space in center of ring, over the total number passing over the top of the same wire through the portion marked B in Fig. 4.. With rings of sufficient cross-section to carry all the lines of force generated by the field magnets without undue crowding and with sufficient diameter of ring to make the path through its center and shaft of very high resistance compared with the nearly saturated ring itself the wire on the inside certainly will be active to a certain extent. Prof. Anthony's claim no doubt holds good with all practical cylinder armatures, but in applying it to ring armatures allowance must be made for the reaction of the lines of force leaking through the center of the ring and those in the ring diametrically opposite the coil under consideration.

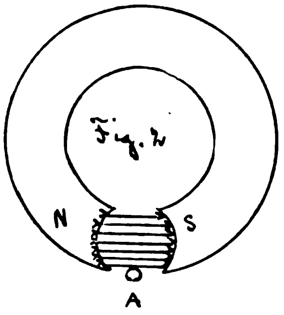

FIG. 2.

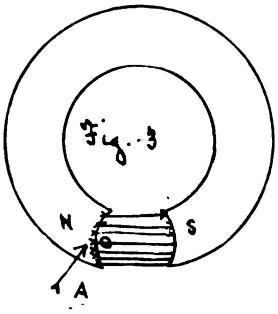

FIG. 3.

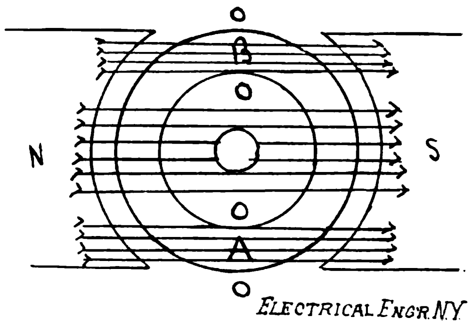

FIG. 4.

ELECTRIC POWER IN THE KEATING BICYCLE FACTORY.

AN installation interesting to bicycle manufacturers in particular and to all other manufacturers in general, is now under way at Middletown, Conn., where the Keating Wheel Co., have just completed a factory unique in its construction and in the application of its motive power. When complete the factory and offices will cover a floor space of 168,250 square feet, of which about 150,000 square feet will be devoted entirely to the manufacture of the well-known Keating bicycle.

The factory is situated on the west bank of the Connecticut River, between the river itself and the Hartford-Middletown branch of the New York, New Haven and Hartford system. The establishment is divided into three buildings of brick and stone. The main building is 1,000 feet long, 50 feet wide and two stories high. Projecting from this on the river side are six L's, each of which is devoted to some special operation on the wheel. Reference to the plan shows the different departments which occupy these L's. The main L, 200 feet long, 50 feet wide and two stories high is the repair department and the store room. The others are respectively, the blacksmith shop, the brazing shop, the polishing shop, the plating shop, and the enameling shop, each of them about 100 feet long and about 50 feet wide.

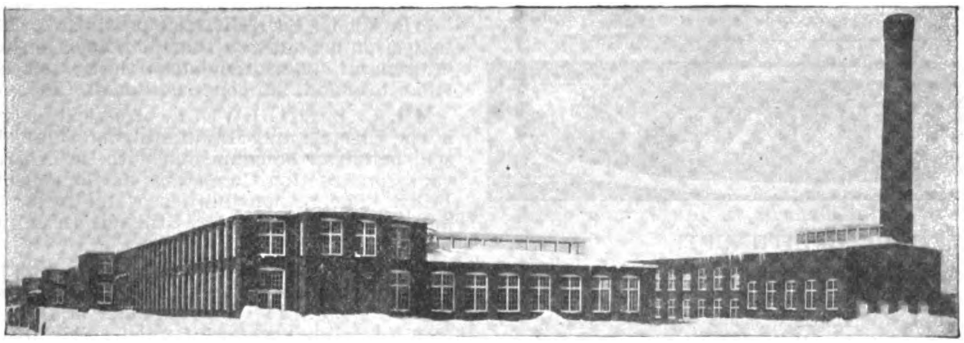

FIG. 2.—VIEW OF KEATING FACTORY, JANUARY 30, 1897.

The northeast corner of the plot will be occupied by spacious offices, 100 feet long by 50 feet wide and two stories high, entirely separate from the factory and yet in sufficiently close touch to make it an integral part of the main factory building.

The unique feature of this factory lies in the fact that it will be entirely operated by electricity, not an engine or a main belt coming into the factory proper. The method chosen is the three-phase system of the General Electric Company. The engine and generating plant is located in the southeast corner of the plot in a two-story brick and stone building. Steam is generated by a Babcock & Wilcox boiler of 250 horse-power, separated by a brick partition from the engine room. The engine, a cross compound condensing Greene engine, of 500 horse-power, the high pressure side only of which is installed, is erected upon the second floor upon brick and stone cap piers built up from the ground. On the same floor is a General Electric three-phase generator, known as an A-T, 16-pole, 250 kilowatt, 450 revolution, 60 cycle machine, also placed on piers carried up from the ground. The main belt from the engine and flywheel passes down to the ground floor, where a countershaft runs in bearings set upon brick and stone piers. The shaft is carried the entire length of the room and from it will be driven eventually another three-phase machine probably of similar capacity, as well as a set of lighting machines, to be erected at Middletown, as soon as they can be removed from the present factory of the Keating Wheel Company, at Holyoke. This countershaft is arranged with couplings so that any portion may be cut in or out as may be required.

The exciter for the generator is a 4½ kilowatt machine of the I. B. type, run from a pulley on the shaft of the three-phase machine. Facing the generator is a Vermont marble switchboard carrying packed card rheostats, current indicator, voltmeter and the necessary switches for controlling the exciter and the generator. From the switchboard, six wires, forming two circuits, issue from one of the windows of the power house and pass to the main factory, supported on one pole only. They are carried above one of the windows on the second floor of the factory and there three of the wires terminate, while the other three, which constitute the circuit in service, follow the center of the roof of the second story for about three-fourths of the length of the whole building. At the proper place they are tapped off, descending their respective pillars and passing through the floor of the second story to the motors suspended from the ceiling of the first story.

The main building 1,000 feet long is one great hall, supported on rows of pine pillars set ten feet apart. It will be seen by the diagram of the building that the main shafting is about 800 feet long and runs down the central aisle, being divided into three sections between each of which is a 50 horse-power G. E. induction motor of the inverted type. There are other shorter lines of shafting which are about 350 feet long, one on each side of the main shafting in the north part of the building. Still another line of shafting about 200 feet long runs through the repair department. The motors that drive the shafting in the main building are two 50 horse-power, while the line of shafting running through the repair shop is driven by a 20 horse-power motor, secured to the ceiling of the first floor in the main building.

All of the motors are equipped with two pulleys on each end so that four independent shafts can be driven from each motor. The extent of this shafting and the method of driving the motors can be gathered from the illustration made from a photograph taken from one end of the main building. There is about 160 feet of shafting on the other side of the far motor shown in the picture; this will give some idea of the extent of the installation.

The entire factory has been laid out by Mr. R. M. Keating himself with all the care which a man can bestow upon a child of his own creation.

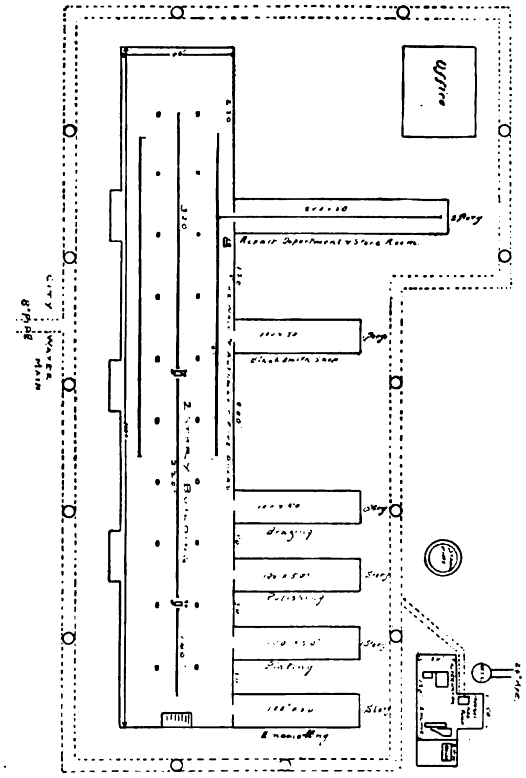

FIG. 1.—LAYOUT OF THE KEATING FACTORY AT MIDDLETOWN, CONN.

OBITUARY

E. CARL BREITHAUPT.

Mr. Carl Breithaupt, an electrical engineer of Berlin, Ontario, Canada, died there on January 27, aged about thirty years. Mr. Breithaupt was for two years a post-graduate student in the electrical department of the Johns Hopkins University, from which he was graduated in June, 1892. His preliminary education was obtained at the Northwestern College, Illinois. After graduating from the Johns Hopkins University he became a member of the Beta Theta Pi fraternity of that institution. Mr. Breithaupt went to Berlin and became the electrical engineer of the Berlin Gas and Electric Light Company and president and general manager of the Berlin and Waterloo Railway Company. He was for some years a member of the executive committee of the Canadian Electrical Association and was last year elected vice-president of the association. He was also a member of the American Institute of Electrical Engineers.

SAMUEL R. WILMOT.

We regret to note that Mr. Samuel R. Wilmot, senior partner of Wilmot & Hobbs, Bridgeport, Conn., dropped dead on February 4. He came to this country from England in 1837. He lived in Brooklyn until 1877, and then went to Bridgeport. He was the pioneer maker in this country of cold-rolled steel tubing, and a very able manufacturer of tools and other specialties. The products of his company have gained a high reputation in the electrical field.

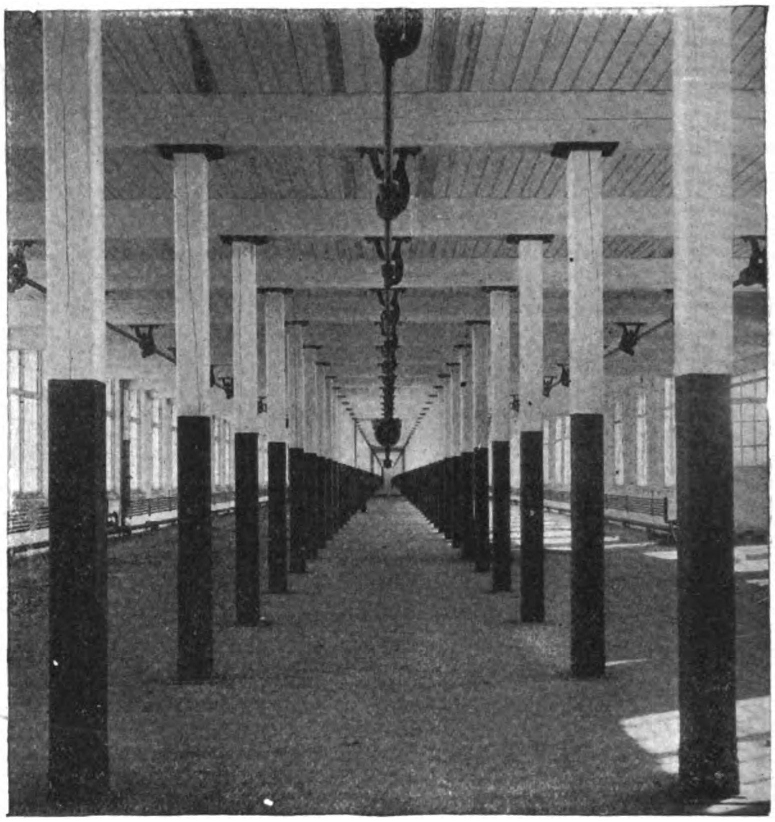

FIG. 3.—FIRST FLOOR OF MAIN BUILDING, 1,000 FEET LONG.

PERSONAL

MR. W. H. BAKER, vice-president of the Postal Telegraph Co., is on a Southern tour of inspection with Mr. L. D. Parker, general superintendent of the system and Mr. C. M. Baker, superintendent of construction at Chicago headquarters.

MR. L. B. STILLWELL, electrical engineer of the Westinghouse Electric and Manufacturing Company, has resigned, and will hereafter be connected with the Niagara Power and Cataract Construction Companies as their electrical director at the Falls. The responsibilities of the new position will be large and growing; but in Mr. Stillwell an eminently wise selection has been made.

MR. T. M. NICHOLL has been appointed general manager of the Rochester Railway Co., in the place of Mr. F. O. Rushling resigned. The new manager is an experienced steam and electric railway superintendent. Mr. Rusling retires to look after some large personal electric railway interests in Canada.

MR. F. S. TERRY, of the Sunbeam Lamp Company, was a welcome visitor in New York last week.

BINGHAMTON, N. Y.—Mayor Green in his annual message pays a very high compliment to the Binghamton Railroad Co. and to its good work under the leadership of President Rogers.

SOCIETY & CLUB NOTES

A NOTABLE DINNER OF THE MAGNETIC CLUB.

THE dinner of the Magnetic Club held on February 3 at the Transportation Club in the Manhattan Hotel, will long be remembered by the participants as one of the most enjoyable of the many meetings held by the club since it was started some six or seven years ago. One notable feature was that it served for the inauguration of the new president, Mr. E. H. Johnson. Another was that it witnessed the presentation of a handsome magnet shaped diamond pin to Secretary George Fagan. A third feature was the celebration of the passing of the bill by Congress and its signing by President Cleveland, which recognizes formally the services during the Civil War of the United States Military Telegraph Corps. All this was capped by a splendid programme of music.

After an excellent menu had been disposed of by about 150 diners, Mr. T. Fleming read a hearty dispatch of congratulations from Past President Mr. W. H. Baker, and introduced the new president, Mr. E. H. Johnson, who was received with the Chautauqua salute of waving napkins and with two rounds of tremendous cheering. Mr. Johnson made a terse and happy address in allusion to his great pleasure in being thus associated with so many old associates of the key, and then referred in glowing terms to the work done by telegraphers in the Civil War. Mr. J. R. Van Wormer, the well-known secretary of the Union League Club, then made an equally eloquent speech laudatory of the United States Military Telegraph Corps and read a series of resolutions congratulating the survivors of the Corps and the families of deceased members of it, on the fact that at last this measure of justice had been accorded. These resolutions were seconded by Mr. Hutchinson, received with great applause, and acknowledged with his wonted dignity and felicity by President A. B. Chandler of the Postal Telegraph Company, who had had the honor of serving at headquarters with Mr. Lincoln as a member of the Corps. He said that had Lincoln and Stanton lived, the recognition would have come long ago.

The Congressional Record of January 20, 1897, page 1012, contains the announcement of the passage of the following bill: "Be it enacted, etc., That the Secretary of War is hereby authorized and directed to prepare a roll of all persons who served not less than ninety days in the operation of the military telegraph lines during the late civil war, and to issue to each, upon application, unless it appears that his service was not creditably performed, or to the representatives of those who are dead. suitable certificates of honorable service in the military telegraph corps of the Army of the United States, stating the service rendered, the length of such service, and the dates, as near as may be, between which such service was performed; provided, That this law shall not be construed to entitle the person herein mentioned to any pay, pension, bounty or rights not herein specifically provided for." The resolutions were as follows: Resolved, That the Magnetic Club of New York conveys to the surviving operators of the military telegraph service of the late civil war, and to the relatives of those who are deceased, its most cordial congratulations and the expression of its profound satisfaction at this official and enduring acknowledgment on the part of the Congress of the United States of brave deeds, efficient service and patriotic devotion to duty. partial and inadequate though the acknowledgment may be when compared with the achievements of those for whom it is designed.

"Resolved, That a copy of this resolution be forwarded to the secretary of the United States Military Telegraph Corps."

Mr. W. J. Dealy then read a number of letters of regret for absence from Gen. Eckert, who has been ill; C. A. Tinker, D. Doren, W. B. Somerville, Gen. McElvey and others, who had served so loyally in the stirring times of old. After this, the audience sang "Columbia," and then Mr. C. C. Cockey presented Secretary George Fagan with a diamond pin. A very earnest and strong speech was made also by Col. W. B. Wilson, one of the leading members of the United States Military Telegraph Corps, who paid a fitting compliment to the steady and arduous work of Mr. W. R. Plum in securing the passage of the bill.

The musical programme had been well selected and comprised songs by Miss Carrie Roma, Mr. J. Stanford Brown and Mr. Fischer Miller; and piano selections by Mr. John Francis Gilder. The proceedings closed with the singing of "Auld Lang Syne." Among those present, other than already mentioned, were President Weir, of the Adams Express Co.; F. J. Sprague, J. H. Bunnell, John Bogart, late State Engineer; C. Cuttriss, C. P. Bruch, C. A. Benton, T. R. Taltavall, J. B. Taltavall, E. L. Powers, C. T. Rittenhouse, A. C. Shaw, T. C. Martin, N. D. Webster, John Brant, P. H. Alexander, W. Marshall, E. C. Platt, W. Maver, Jr., J. H. Emerick, J. E. Ham, A. Henderson, A. P. Eckert, E. Davidson, M. M. Davis, Francis W. Jones. Great credit is due to Messrs. T. A. Brooks and O'Leary for the success of all the arrangements.

PROF. PECKHAM ON THE SPACE SURROUNDING A WIRE.

A LECTURE on the space surrounding a wire over which an electric current is flowing was given in the Physical Lecture Room of Adelphi College on Friday evening, February 5, before the Department of Electricity of the Brooklyn Institute, by Professor W. C. Peckham. Both the direct and alternating currents were used. The effects of currents on each other and on magnet poles were experimented upon. The attraction and repulsion of parallel currents were shown by a long wire doubled in the middle and hung in the room. When the current was sent through the wire the two sides bent away from each other six inches. To show the effect of a current on a magnet, a wire was passed through the bottom of a glass tank placed over the lantern, and a magnetized sewing needle was floated on the water in the tank. By reversing the current in the wire the needle was made to sail upon the water and to whirl on its axis. This experiment was original with the lecturer.

The phenomena of the alternating current field of force were shown by rings, coils of wire, and by the glowing filaments of incandescent lamps. The electric waves from an induction coil which was operating an X-ray tube in an adjoining room were traced by a coil and telephone, 30 feet from the coil. The induction of one coil or another was shown, making a telephone emit a note so that it could be heard in all parts of the room. The alternations of the electric current were used to make the filament of a lighted lamp vibrate in most beautiful forms.

The lecture closed with a description of the present condition of the problem of telegraphing without wires. and of signaling to ships off shore in a fog.

THE STOCK MARKET

MIDWINTER CONDITIONS.

ONE of the current reports in electrical circles has been that a selling company may be organized to handle all the General Electric products, but the rumor entirely lacks confirmation from the inside, although it may be one of the means adopted for "reorganization." The fact also that lamp makers were being licensed under the Weston group of patents has become generally known. It is regarded in many quarters as likely to have a good influence in keeping up prices of lamps, and restoring them to a living level. It may also lead to lamp importations from abroad, particularly Germany. If the license system had been adopted long ago, everybody in the business would have been better off, the General Electric Co. included.

The Albany "Argus" has the following in regard to General Electric finances: "It comes from good authorities that the gross business of the General Electric Company for the past year has been about $11,000,000, or some $2,000,000 less than expected, and likewise $2,000,000 less than in 1895, but the company has improved its fiscal and financial position and is now in shape to quickly do a business of $1,500,000 per month as soon as it shall be offering. At present it is doing about $1,000,000 gross business per month. The net returns for the fiscal year closing at the end of January will be just about the same as last year—$1,900,000 net earnings and $1,100,000 surplus after interest and charging up of accumulated dividends on preferred stock. The surplus will of course go toward the reduction of the capital impairment. The capital account will also be improved by about $300,000 as the company has made sales of assets during the year of $300,000 above last year's book valuations."

The stock market was inactive last week, with very few wide fluctuations. Of Western Union, 11,965 shares were sold, between 84¼ and 83; of American Bell, 751 shares with a rise of 4¼ points to 217; of General Electric, 23,404 shares around 35¾ for the week. The rise in Bell stock is attributed to the adjourning of the United States Supreme Court without a decision in the Berliner case.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

BY MAX OSTERBERG.

Accumulators:

THE BLOT ACCUMULATOR.—A new type of accumulator consisting of lead, Planté type, formed in the usual way without paste. Plates consist of a lead frame in which are suspended a number of spools of corrugated and embossed lead tape wound on a long lead core, the axis of the core being perpendicular to the plane of the plate.—Lond. "Elec. Eng'r.," Jan. 15, '97.

Biographical:

JACOB BRETT.—An obituary notice with a short review of the life of one of the pioneers of telegraphy in England.—Lond. "Elec. Eng'r.," Jan. 15, '97.

Central Stations:

ELECTRIC LIGHT STATIONS AND GAS ENGINES.—A short abstract of the central station in Leyton, England, where producer gas is used to drive gas engines.—"Elec. Rev.," Jan. 27, '97.

BROOKLYN BRIDGE NEW ELECTRIC POWER PLANT.—Detailed description of the plant with a number of views and diagrams showing the special features in this undertaking. Six feeder cables are laid for distributing the current to three sections, the total length of feeders being between 3½ to 4 miles. They are laid parallel to the tracks on the top of glass insulators set on wooden cross-arms, and tied to the insulators so as to prevent their beeing displaced. In addition to these feeders there are four return conductors each of 500,000 circular mils.—"Elec. World," Jan. 23, '97.

CENTRAL ELECTRIC STATION OF THE DAVIS COAL AND COKE COMPANY.—By Timothy W. Sprague. This company is the first in W. Va. to adopt electricity in connection with mining operations. The generator running at 900 revolutions per minute, has a 100 kilowatt capacity, a potential of 500 volts, and is of the three-phase alternating current type. The power is at present used in coal cutting, and in the operation of five elevators and conveyors. The coal-cutting circuit runs a distance of a little over one-half mile in two directions.—"Eng. and Min. Jour.," Jan. 23, '97.

BIRKENHEAD ELECTRICITY WORKS.—A municipal plant working on a two-wire 230 volt system, with switchboard, feeders, and distributing mains designed for a three-wire system. Three 80 horse-power steam dynamos now erected are wound to give about 250 volts, and hence will eventually supply one side of the system only. The larger units to be added will, of course, deliver current to the two outside wires at something over 460 volts. Three Lancashire two-flue boilers working at 160 pounds pressure are installed. The steam engines are of the Willans single acting central valve type, compound non-condensing. The storage battery outfit having a capacity of 750 ampere hours, capable of discharging for five hours consecutively at the rate of 150 amperes, or for one hour at the rate of 400 amperes, is part of the central station outfit. For further details of switchboard, mains, load of station etc., see Lond. "Elec. Eng'r.," July 15, '97.

ST. HELEN'S ELECTRICITY WORKS.—Detailed description of the plant and buildings. The principal features are as follows: Two Lancashire boilers at 140 lbs. pressure, two engines for driving alternators, one of 180, the other 50 i. h. p., when running 98 revolutions per minute. Two alternators, one 25 kilowatt, 2,000 volt alternator, 350 revolutions per minute, and one 100 kilowatt 2,000 volt alternator, 100 revolutions per minute supply the electricity for the town. Several diagrams indicate the position of the distributing mains and feeders.—Lond. "Elec. Eng'r.," Jan. 15, '97.

Dynamos and Motors:

CALCULATION OF THE IRON LOSSES IN ALTERNATORS OF THE SO-CALLED INDUCTION TYPE.—By Dr. Behn-Eschenburg. Author deduces a mathematical formula from which the iron losses can be calculated.—"Elek. Zeit.," Jan. 14, '97.

THE DESIGN OF A 100 KILOWATT 500 VOLT POWER GENERATOR.—By H. J. Ryan and I. J. Macomber. Authors explain that two methods may be used for designing a dynamo. In the first the e. m. f., current and speed are specified, and the desired electrical and commercial efficiency assumed. In the second method the designer has given the desired output of the electrical generator at some required pressure and the condition of operation. Here the designer keeps in mind mainly the duty of the machine, and the necessary mechanical and electrical features that will provide the proper behavior and durability consistent with practical commercial efficiency. No machine can be successfully made by adhering strictly to either one of these methods, but rather by a combination of the two. Following the introductory remarks is an outline with explanatory notes for the design of direct current generators and motors, ending with a numerical example fulfilling the conditions under the heading.—"Sib. Jour. of Eng.," Jan., '97.

TWO-PHASE ALTERNATORS.—Description of the dynamos of the Electric Light and Power Company in France, giving details of construction with a diagram of the armature connections.—"L'Ind. Elec.," Jan. 10, '97.

Electro-Chemistry:

ON THE APPLICATION OF ELECTROLYSIS FOR THE PREPARATION OF BLEACHING COMPOUNDS AND ALKALIES.—By Dr. Carl Kellner. A number of patent abstracts explaining methods best suited for different purposes, such as for the bleaching on a small or large scale, or for bleaching compounds prepared for immediate or for future use.—"Elek. Echo," Jan. 9, '97.

ELECTROLYTIC DECOMPOSITION OF FUSED ZINC CHLORIDE.—By Richard Lorenz. A determination of the voltage required to decompose pure fused zinc chloride gives the number 1.49 to 1.50 volts. Three different strengths of current were employed in the experiments, and the result obtained from each agree closely. The theoretical voltage is 2.1, but it must be remembered that the temperature at which the experiments were carried out was 500 to 600 degs.—Zeit. f. Anorg. Chem., 1896, Vol. 12. Note in Lond. "Elec. Rev.," Jan. 15, '97.

Electric Heating:

ELECTRIC HEATING.—A system patented by Helberger prevents the air from coming in contact with heated wires in the electrical heaters by surrounding the heated surface with a thin insulating and fireproof material. The cost per hektowatt is 4-10 cent. A coffee machine, for example, holding 100 cups or 22 litres requires 40 amperes for 30 minutes at a cost of 8 cents, current keeping the same warm costs 4-10 of a cent per hour.—"Elek. Anz.," Jan. 14, '97.

Electro-Physics:

VISCOSITY OF POLARIZED DIELECTRICS.—Non-conducting liquids when subjected to electrostatic stress undergo mechanical changes. The principal observers in this line of research are Quincke, Röntgen, Kerr, König, Pagliani, and lately A. Wilmer Duff. The latter's experiments consist in testing the change of viscosity in fluids, such as castor and paraffine oils. A drop of mercury is allowed to drop through a small tube, and the time of fall observed while the condensor plates highly charged are at opposite sides of the glass tube, and then while no electrical conditions are applied to influence the fall. In some cases a change as much as ½ of 1 per cent. in the viscosity has been observed.—Lond. "Elec. Rev.," Jan. 15, '97.

ON THE RELATION BETWEEN THE HALL EFFECT AND THERMOELECTRICITY IN BISMUTH AND IN VARIOUS ALLOYS.—By J. C. Beattie. On arranging metals in the thermoelectric series it appears that those with an extreme position thermoelectrically have a corresponding extreme position as regards the Hall effect, although various irregularities appear. The author adds measurements at varying temperatures of the Hall effect with bismuth, and the electromotive force of the thermocouple Bi-Pb, and remarks that we may not yet maintain the transverse effect to be a function of the thermoelectric force. Proc. Roy. Soc. Edinb. No. 21, '96. Note from Jour. Phys. Chem., Jan. '97.

Lighting:

DISTRIBUTION AND DIFFUSION OF LIGHT.—By E. L. Elliott. Abstract of a paper read before the N. Y. Elec. Soc. The principle of the holophane globe is described and its advantages over other types of diffusing globes demonstrated. Illus. "Elec. World, Jan. 23, '97.—"Elec. Engr.," Feb. 3, et seq. more fully.

ELECTRIC LIGHTING AT BROWN'S HOTEL, ALBERMARLE STREET, LONDON.—Two 16 brake horse power Crossley gas engines with tube ignition, drive the dynamos as well as a line of shafting. The main flywheels drive two 185 ampere, 130 volt dynamos at a speed of 500 revolutions per minute. Three sets of accumulators are used, 55 cells in each set.—Lond. "Elecy.," Jan. 15, '97.

Mechanical;

ELECTRICALLY DRIVEN AIR COMPRESSOR.—A short description with illustration of a machine furnishing 15 feet of free air per minute, on a pressure of 60 lbs. per square inch. —"Rail'y Rev.," Jan. 23, '97.

ENGINE TESTS.—Some interesting figures of two tests made with the Pollit and Wigzell engines which are of the compound horizontal tandem type of about 400 indicated horse power capacity, show 1 9-10 lb. of coal per indicated horse power hour with 7 4-10 lbs. of feed water evaporated per lb. of coal under actual conditions.—"Lt'ng.," Jan. 14, '97.

HAND PRESSURE ELECTRIC DRILL.—This drill, weighing 46 pounds, capable of boring holes up to three-eighths inch in diameter, runs at about 300 revolutions per minute and consumes 2 amperes at 110 volts. Thirty-five holes can be drilled per hour, while but about 8 can be drilled by hand. The drill spindle is driven by reducing gear by an electric motor, which can be carried around and held in any position required.—Lond. "Elec. Rev.," Jan. 15, '97.

Miscellaneous:

TESLA ON ELECTRICITY.—An address on the occasion of the commemoration of the introduction of Niagara Falls power into Buffalo, delivered Jan. 12, '97. The speaker reviewed the great progress made in transmission of power, and gives in popular language his reasons for calling this the Electrical Age.—"Elec. Rev.," Jan. 27, '97.

Railways:

THE APPLICATION OF MOTORS FOR STREET RAILWAYS, ESPECIALLY WHERE UNDERGROUND FEEDERS ARE USED.—By Eduard Lachmann. The general tendency of the railway companies appears to be to work at higher voltage. He believes that larger cars, or cars with a number of trailers will be in common use shortly. Of the storage batteries for use on cars he does not think favorably since they would occupy, especially on the high voltage, too much space.—"Elek. Rund.," Jan. 15, '97.

Roentgen Rays:

THE FIRST RADIOGRAPH SHOWING ARTERIAL CIRCULATION.—An illustration showing the brachial artery and its bifurcation at, or near the elbow into the radial, and ulnar arteries. It is believed that the reason why the artery has been made visible is due to the fact that the patient had an unusual supply of lime salts in the blood.—"Elec. Rev.," Jan. 27, '97.

DR. FLEMING'S LECTURE ON THE X-RAY.—In a lecture delivered at the London Institution Prof. J. A. Fleming reviewed the development of the X-ray, and showed among others a picture of the bones of a mummy 4,000 years old.—Rep. in the Wld. of Sci. Abst. in "Elec. Rev.," Jan. 27, '97.

NEW CROOKES TUBES.—By Drs. Oudin and Barthelemy. A short description of a double focus tube to be used on an alternating current dynamo, low or high frequency.—"La Nat.," Jan. 9, '97.

EFFECT OF ROENTGEN RAY ON PARAFFINE IN RESPECT TO ELECTRIC CONDUCTANCE.—By Lord Kelvin, Dr. Beattie and Dr. Smolan. A series of careful electrometer tests show that there is no appreciable change in the conductivity of paraffine when under Röntgen ray influence.—Lond. "Elec. Rev.," Jan. 15, '97.

Wires, Wiring, etc:

PRINCIPLES OF ELECTRICAL DISTRIBUTION.—By Prof. Francis B. Crocker. The sixth of a series of articles describing feeder regulation. After considering that the sole merit of the three-wire system lies in the saving of copper, which, of course, is so great an advantage that it makes the use of the system imperative, the following disadvantages are enumerated: (1) It is usually necessary to operate at least two dynamos, or other sources of current. (2) It is necessary to lay and take care of three wires instead of two. (3) The switches, cut-outs, measuring instruments, etc., are more complicated. (4) The saving of copper stated assumes that the neutral wire carries no current. (5) The variation in potential is aggravated by the increase that sometimes takes place, which is impossible on a two-wire circuit.—"Elec. World," Jan. 23, '97.

A NEW SYSTEM OF INSTALLATION AND SAFETY MATERIALS ACCORDING TO THE RULES PRESCRIBED BY VERB. DEUTSCHER ELEKTROTECHN.—By Hundhausen. Author explains a great many details consisting of cutouts, switches, fuses, etc.—"Elek. Zeits.," Jan. 14, '97.

* * *

BUFFALO.—The Buffalo General Electric Co. bids 33 cents a year for city lamps per night, 2,000 candle-power, or 30 cents if given a five years' contract, or $100 per year, for five years if over 2,500 lamps are used, without extra charge for underground conduits to the extent of 75 continuous lamps.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JANUARY 12, 1897.

Alarms and Signals:—

AUTOMATIC BLOCK SYSTEM. J. Shoencraft, Harveyville, Kan., 576,166. Filed May 7, 1896.

Provided with a closed electric circuit comprising a ground-wire containing a battery and the signal magnets, and a second wire connected with the ground-wire at the station at the end of the section, each wire containing a relay, of which the armature forms part of the other wire.

ALARM FOR ELECTRIC CIRCUITS. C. B. Sterling, New York, 576,383. Filed June 24, 1895.

Means whereby an attendant will be informed when a switch has been burned out by reason of the overloading of the line.

ELECTRICAL CIRCUIT FOR OPERATING AUTOMATIC RAILWAY GATES. J. S. Biggar, Chicago, Ill., 576,493. Filed Jan. 22, 1895.

Employs two electrical circuits successively closed by the movements of a car to close and open the gate, and an intervening circuit, also, closed by the car, which holds the second circuit open until the entire train has passed a predetermined point.

Batteries, Primary:—

BATTERY. W. S. Doe, Brooklyn, N. Y., 576,095. Filed Feb. 29, 1896.

Comprises a hollow cathode, a perforated tube of non-conducting material suspended therein, an anode in the tube having a side opening, a depolarizer in the anode, a conductor-wire for engagement with the anode, and means for yieldingly holding the anode against said wire.

Batteries, Secondary:—

PASTE CARRYING MACHINE FOR ELECTRIC ACCUMULATORS. F. W. Schneider, Triberg, Germany, 576,163. Filed Jan. 13, 1896.

Consists of a frame and paralleled bars therein having lateral projections, and being connected each to the next by bridges in form of undulating or zigzag bands, the bridges having respectively on their front and rear sides lateral openings and central projections perpendicular to the faces of the plate.

CONSTRUCTION OF CELLS FOR ELECTRIC ACCUMULATORS. F. W. Schneider, Triberg, Germany, 576,164. Filed May 2, 196.

Intended for accumulators for use in vehicles.

ELECTRODE FOR STORAGE OR OTHER BATTERIES. T. A. Willard, Norwalk, Ohio, 576,177. Filed Nov. 7, 1895.

Similar to above.

BATTERY PLATE. T. A. Willard, Cleveland, Ohio, 576,178. Filed May 4, 1896.

A battery plate having its sides provided with extremely thin parallel shaved leaves of equal thickness with a uniform space between the leaves in which the material is enabled to form and expand.

Connectors, Conduits and Insulators:—

INSULATOR. H. E. Billings, Hartford, Conn., 576,392. Filed Nov. 21, 1896.

Trolley hanger.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. P. H. Fielding, New York, 576,103. Filed April 23, 1896.

Enclosed arc projection lamp.

ELECTRIC ARC LAMP. D. A. Shesler, Toledo, Ohio, 576,475. Filed Feb. 13, 1896.

Mechanism for effecting an extension of the arc between the tips of the carbons.

Measurement:

ELECTRIC METER. J. R. Tucker and C. C. Hinckley, Aurora, Ill., 576,240. Filed Jan. 25, 1896.

Employs a planimeter wheel in connection with a registering device.

ELECTRIC METER. Reissued. J. Harris, Lynn, Mass., 11,588 Filed Aug. 6, 1895.

Comprises a pressure coil and its supporting shaft in combination with a spring connected to the shaft and brought under tension by the torque of the coil.

Miscellaneous:—

ELECTRICAL ADVERTISING DEVICE. L. Julig, San Francisco, Cal., 576,129. Filed Dec. 26, 1895.

Details of construction.

AUTOMATIC STREET OR STATION INDICATOR AND ADVERTISING MEDIUM. M. B. Leece and A. R. Bullock, Cleveland, O., 576,201. Filed June 2, 1896.

Details of construction.

SOUNDING APPARATUS. A. M. Lozier, New York, 576,208. Filed April 24, 1896.

Employs a sinker containing a device which is moved by the variations of a hydrostatic pressure, a rheostat varied by the movement of the device, and electrical devices adapted to respond to variations of resistance.

MUSIC RECORDING APPARATUS. E. K. Adams, New York, 576,245. Filed Oct. 21, 1896.

Apparatus for producing patterns for the sheets of Regina music boxes.

ADVERTISING DEVICE. H. Green, Hartford, Conn., 576,266. Filed Feb. 8, 1896.

An incandescent light globe having a capped or coated surface and provided with a letter on one or more of its sides.

ADVERTISING DEVICE. H. Green, Hartford, Conn., 576,267. Filed May 2, 1896.

Comprises an incandescent electric light globe and a freely removable letter plate having means for directly engaging the globe.

ELECTRICALLY OPERATED MUSICAL INSTRUMENT. G. H. Davis, New York, 576,342. Filed March 25, 196.

Means for effecting economy in the electrical energy necessary to actuate the sounding mechanism.

ELECTRIC HEATER. F. A. Johnson, Binghamton, N. Y., 576,347. Filed Feb. 24, 1896.

A magnetic-induction heater, comprising a case having an opening to receive the article to be heated.

APPARATUS FOR STOPPING ENGINES. G. W. Brown, West Newbury, Mass., 576,514. Filed Oct. 4, 1895.

Details of construction.

Railways and Appliances:—

AUTOMATIC SWITCH. J. P. Alexander, Jackson, Tenn., 576,082. Filed May 29, 1896.

Comprises a divided and balanced circuit, switching devices connected in a bridge across the circuit, mechanical means for disturbing the balance of the circuit, and connections controlled by the switching devices for closing a supply circuit whenever the balance of the balanced circuit is disturbed.

METHOD OF AND APPARATUS FOR ELECTRICAL PROPULSION. L. H. Nash, South Norwalk, Conn., 576,145. Filed Nov. 16, 1895.

Comprises an electric generator having shunt and series coils, the currents through which flow in opposite directions with a series wound motor.

CONTACT BOX FOR DEPRESSIBLE CONDUCTOR RAILS. W. Grunow, Jr., Bridgeport, Conn., 576,268. Filed May 8, 1896.

Details of construction.

LOCKING DEVICE FOR ELECTRIC CONTROLLERS. G. Valley, Johnstown, Pa., 576,332. Filed Nov. 10, 1896.

Comprises two contiguous rotatable discs, one of the discs having a plurality of lunes about its periphery, the other having a plurality of suitably connected concentric arcs composing its periphery.

ELECTRIC CONTROLLER. G. Valley, Johnstown, Pa., 576,333. Filed Nov. 10, 1896.

Consists of two operating drums and an electric switch which affords means whereby either drum alone or both drums together may be used to supply electric current for propelling the vehicle.

BRAKE MECHANISM AND CONTROLLER FOR ELECTRIC CARS. W. D. Thomas and L. R. Gignilliat, Savannah, Ga., 576,384. Filed June 2,1896.

Means whereby the brake mechanism and current regulator may both be operated from a single operating shaft.

TROLLEY FOR ELECTRIC CARS. G. L. Campbell, Shunk, Pa., 576,394. Filed March 18, 1896.

Device for keeping trolley on wire.

SPIRAL TROLLEY WHEEL. C. A. Langford, St. Louis, Mo., 576,405. Filed May 25, 1896.

Details of construction.

Switches, Cut-Outs, Etc.:—

RHEOSTAT. H. W. Leonard, East Orange, N. J., 576,202. Filed July 30, 1896.

Comprise a cast-iron plate or support, a layer of infusible material thereon, and a conductor embedded in a layer of glass adherent to the fusible layer.

AUTOMATIC ELECTRIC CUT-OUT. C. C. Kritzer, Newaygo, Mich., 576,369. Filed Nov. 13, 1895.

Comprises an electromagnet in the main circuit, an armature adapted to respond to an abnormal current, a spring actuated frame pivoted at one end, contact plates on the base plate, contacts mounted on the free end of the frame, a hook to hold the frame, and a latch released by the action of the armature, the hook being carried by the latch.

Telegraphs:—

CONTACT APPARATUS FOR TELEGRAPHING. C. Vreede, Rotterdam, Netherlands, 576,243. Filed Jan. 6, 1896.

Adapted for use in conjunction with semaphoric signaling.

Telephones:—

AUTOMATIC ELECTRIC CUT-OUT FOR MAGNETO-BELLS. J. Z. Miller, Baltimore, Md., 576,372. Filed Sept. 23, 1896.

Mechanical means adapted for attachment to any bell for automatically cutting into the telephone circuit both sides of the magneto-generator bell by the act of turning the magneto bell crank, and of cutting out the generator by the act of releasing the bell crank.

SPRING JACK. W. S. Paca, Baltimore, Md., 576,375. Filed Sept. 23, 1896.

Details of construction.

SWITCH PLUG. W. S. Paca, Baltimore, Md., 576,469. Filed Sept. 23, 1896.

Comprises alternate sections of metal and insulating material provided with screw and socket joints and abutting shoulders, the ends of the wire being secured between the abutting shoulders in electrical contact with the metallic sections.

TELEPHONE SIGNAL TRANSMITTER. E. C. Robes, Medford, Mass., 576,472. Filed July 25, 1896.

Means for sending successive independent arbitrary signals, motor mechanism actuating the same, a telephone hook switch controlling the motor mechanism and means for simultaneously closing the circuit and locking the transmitter mechanism.

LEGAL NOTES

INFRINGEMENT TELEPHONE SUIT IN PHILADELPHIA—ROSE PATENTS AND OTHERS.

The Philadelphia Standard Telephone Company, Joseph H. Mann, president, and Richard W. Clay, treasurer, has filed answer to the bill in equity of the Standard Telephone Company and Mutual Standard Telegraph and Telephone Company, in which infringement of patent is charged. In the answer it is admitted that Allen W. Rose is the inventor of certain improvements in telephone transmitters, for which he obtained a patent in December, 1886. The patent, it was stated, afterwards was transferred to the National Telephone Company, which subsequently sold and assigned it to Allen T. Nye, who sold it on May 1, 1895, to the Standard Telephone Company.

The defendant company annexed to the answer its license, as requested in the interrogatories to the bill, and concluded by asking the court to dismiss the plaintiff's bill.

The Standard Telephone Company, the Union Traction Company and Allen T. Nye filed answers in the same court to the bill in equity of the Western Telephone Construction Company, in which infringement of patented improvement of combined annunciator and spring-jack is alleged. The defendants deny that they made, used or vended switchboards containing and embodying the patented invention.

THOSE SIX INCHES.

Senator Lexow introduced in the New York State Senate a bill aimed to settle the difficulty over the ownership of six inches of land occupied by the Western Union Company in New York, in Broad street, and claimed by the Postal Telegraph Company. It says that where real property consists of a strip of land not exceeding six inches in width, upon which there stands the exterior wall of a building erected partly on such strip and partly on the adjoining lot, and the defendant has been in possession of said strip, enjoying the use of said wall, for upward of one year prior to the commencement of the action, and the plaintiff has erected a building on the lot abutting on the wall, an action cannot be maintained for recovery of the six inches. The site is that on which the new building of the Commercial Cable Co. is going up.

THE TESLA PATENTS REVOKED IN GERMANY.

As was announced in these columns several weeks ago, two of Mr. Tesla's patents have been revoked in Germany. We now learn that these patents are numbered 47,012 and 47,885, respectively, and entitled "Combination of a Transformer and a Source of Current," and "Connection of the Coils of Current Generators with Motors."

KANSAS.—A bill has been introduced in the legislature creating a board to examine telegraph operators with the object of preventing accidents due to incompetency.

W. K. FREEMAN has been sentenced to 7 years and 9 months in State prison for assault on the girl, Sarah Work. On his previous trial, he was sentenced to ten years. The attempt to fix conspiracy on Mr. C. A. Terry and other officials of the Westinghouse Company, failed utterly.

REPORTS OF COMPANIES

OTTAWA, CAN., ELECTRIC CO.

The report of the directors of the Ottawa Electric Company for 1896 is a most encouraging one. The amount of business done is steadily growing, the number of passengers carried last year having been 4,583,235. The gross receipts were $212,105 and the net profits $67,745. The sum of $60,369 is now standing to the rest account of the company. At the annual meeting attention was drawn to the fact that the mileage of the company is greater than that of any other city in Canada, according to population, and twice that called for by the agreement with the corporation. Four quarterly dividends of 2 per cent. have been declared.

STANDARD UNDERGROUND CABLE CO.

THE annual meeting of the stockholders of the Standard Underground Cable Company was held at Pittsburg, on January 26, over 90 per cent. of the capital stock of $7,000,000 being represented in person or by proxies. The old board of directors was re-elected for the ensuing year, among them being one prominent gentleman who entered the board during 1896, namely, Hon. B. F. Jones, of Jones & Laughlins, Ltd., one of the largest iron manufacturers in the United States.

The report showed a total business of nearly three-quarters of a million dollars for the year 1896. Four dividends of two per cent. each were paid out of the earnings for the year, and the remainder was added to the surplus account.

The assets of the company aggregate $1,412,046.06, and the liabilities, exclusive of capital stock, are $106,928.08, while the surplus over and above all liabilities (including capital stock of $1,000,000) is $308,107.19.

The company's factories are reported in first-class condition for economic and rapid manufacture of wires and cables of all kinds, all departments running, and the rubber department being especially crowded with orders at this time.

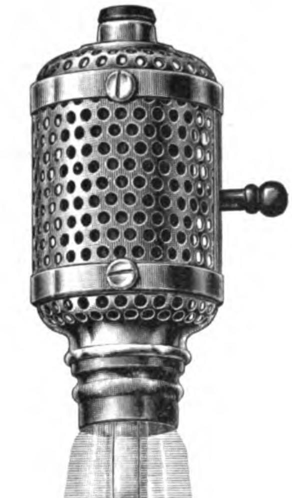
The prospects for 1897 are considered very flattering, a number of large contracts, aggregating nearly $250,000 being now on the company's books, most of which have been secured since January 1, and covering all classes of the company's products. A specially gratifying feature pointed out by the board of directors, is that the number of customers on the company's books for the year 1896 is 50 per cent. greater than for any previous year.

TRADE NOTES & NOVELTIES

BRUNT AND THOMPSON'S NEW REGULATING SOCKET.

We illustrate herewith a regulating socket for incandescent lamps, which is now being placed upon the market by Brunt & Thompson, East Liverpool, O. These sockets are made for either direct or alternating current of 110 volts for use in connection with 16 candle-power lamps.

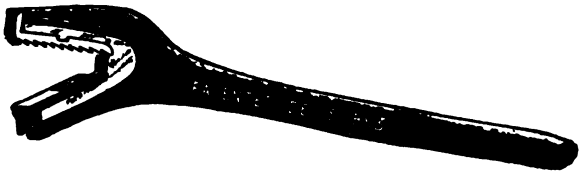
The Chicago Edison Company and the Western Electric Company have made thorough tests of these sockets, and it is asserted that the socket effects a saving of 40 per cent. in current when turned down. These sockets permit of the light being turned down to a lower degree of brilliancy and are especially adapted, therefore, for use in office, sick room, hotels, closets, etc. The light can be turned up and down from 2 candle-power to 16 candle-power, the same as one would operate a gas jet. The firm believes that it has in this socket overcome all difficulties hitherto experienced in the use of apparatus of this class and it guarantees the device to do all that is claimed for it, providing it is used in the manner directed. The sockets are finished in lacquered brass, antique copper and nickel plated.



New Regulating Socket

MARTINI'S PATENT LAG AND PIPE WRENCH.

The Martini's patent lag and pipe wrench shown herewith is a new departure in the line of an automatic wrench, and has a number of very desirable features. The movable jaw at the top causes it to tighten as the pressure on the handle is increased. It will not slip, takes hold and lets go suddenly and is always ready. In the operation of this wrench there is no lost motion, and no time is lost in adjusting. The wrench is made of drop forged steel, and the jaws of the best tool steel hardened and tempered and can be replaced when necessary at a very little expense.



Martini's Patent Lag and Pipe Wrench.

This specialty has had the approval of practical men familiar with this class of tools, and is already being very extensively used. It promises to be a very desirable specialty, as it accomplishes all the purposes of a much more complicated and expensive tool. The Electric Appliance Company have undertaken to put this wrench on the market, have the exclusive sale for same, and report that prospects for a big business on it are very encouraging.

A. E. H. CORPORATION LAUNDRY IRON.

The almost universal use of electric lights in hotels and apartment houses interferes seriously with the use of many of the old-fashioned household conveniences, and being alive to the needs of the times the American Electric Heating Corporation of Boston in addition to providing small portable stoves, chafing dishes and curling iron heaters (which may be attached to lamp sockets), now offer to the trade a small laundry iron of very convenient form and handsome finish. It is especially designed for the sewing room and for ironing laces, handkerchiefs and other light work, for shining up the master's silk hat, and pressing his trousers, on a pinch, though a heavier iron would be better for that. The current required is two amperes on 110 volt circuits and the iron is made for direct or alternating current and for all the usual voltages, as, in fact, are all of their appliances. A feature of all of the new electric heating appliances is that they reach the desired temperature in from two to three minutes and because of their perfect cleanliness and other conspicuous advantages over the older methods, seem to be ideal.

JOHN SIMMONS CO.

The above firm, of 106—110 Centre street, had a very interesting and artistically arranged exhibit at the gas exhibition recently held at Madison Square Garden. Their exhibit comprised a large line of special cocks for gas, full weight wrought iron pipe, all styles gas log valves, fancy handles, a complete line of the Dart Manufacturing Company's special self-lubricatng cocks and the Erie Patent Union. For the last two specialties they are the New York agents. A pipe cutting machine in full operation was also shown, the power furnished by a small Vreeland gas engine. The Jno. Simmons Company cut and prepared in their shops the columns supporting the magnificent Tiffany glass tower. There were a large number of them and every column had to be cut and fitted absolutely perfect. The work was admired by all and will prove a lasting advertisement for the John Simmons Company. Quite a number of orders were taken at the exhibition. In the electric trade this company is supplying wrought and cast iron pipe, valves, fittings and supplies, also the Excelsior railway bracket for trolley roads, etc.

MR. H. K. GORKE.

Mr. H. J. Gorke, who for a long time held the position of secretary and general manager for the Electrical Engineering and Supply Company, of Syracuse, N. Y., has resigned from that company and entered into business for himself at 120 The Bastable, Syracuse, as manufacturer's agent handling electric light and power machinery and general electric supplies. Mr. Gorke will represent a number of the leading houses of this country, such as the Eddy Electric Manufacturing Company, the Perkins Electric Switch Manufacturing Company, the Electric Construction and Supply Company and many others. He is well known throughout electrical circles, and is thoroughly familiar with electrical conditions.

ADVERTISERS' HINTS

THE STANDARD THERMOMETER AND ELECTRIC COMPANY, Peabody, Mass., state their Upton low tension arc lamps are equally adapted for inverted arc service for mill work, or where a reflected light is desirable.

EDW. F. WHITE, 136 Liberty street, New York, furnishes completed steam condensing equipments.

THE PURITAN ELECTRIC COMPANY, 150 Nassau street, city, call attention to the ease with which their long-burning lamps may be trimmed.

KEASBEY & MATTISON COMPANY, Ambler, Pa., advertise sectional magnesia coverings for steam pipes, tanks, boilers, heaters, cylinders, etc.

BRUNT & THOMPSON, East Liverpool, Ohio, carry any desired size of porcelain insulating tube in stock. The business in their regulating sockets grows daily.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, Ill., are introducing a lag and pipe wrench combining simplicity and automatic adjustment.

PEERLESS RUBBER MANUFACTURING COMPANY, 16 Warren street, New York, say their "Hercules" packing leaves the stem clean.

THE ELECTRICAL BROKERAGE COMPANY, Elkhart, Ind., offer bargains in everything electrical.

THE KEYSTONE ELECTRICAL INSTRUMENT COMPANY, Philadelphia, Pa., show a cut of their type "K" instrument.

THE GENERAL ELECTRIC COMPANY, 44 Broad street, city, manufacture every variety of socket, cut-out, etc.

WHITMAN & COUCH, 196 Summer street, Boston, Mass., remind the trade that they are the sole special selling agents of the Ericsson Swedish microphone for the United States.

THE McDERMID MANUFACTURING COMPANY, Chicago, announce that they have a supply of all sizes of battery coppers and will send prices on application.

WESTERN NOTES

LOUIS R. COMSTOCK COMPANY, of Chicago, have made an assignment, which is attributed to hard times and bad collections. The assets are put at $52,000, and the liabilities at $38,000.

THE EVANS ELECTRIC COMPANY, to make electrical supplies, has been formed at Chicago, with a capital stock of $2,000 by A. T. Evans, T. Durham and W. Simpson.

THE ST. LOUIS ELECTRICAL EXCHANGE is reported by the local papers to have had a Seeley dinner at its fifth annual celebration, one of the performers appearing only in the voluminous garb of a pair of dancing slippers.

NEW YORK NOTES.

MR. JOHN C. KNIGHT, of the Diehl Manufacturing Company, has accepted the position of treasurer and manager of the People's Electric Light and Power Company, of Oswego, N. Y. His many friends wish him abundant success in his new enterprise.

A. L. BOGART, of Union Square, had a very interesting exhibit at the gas exhibition just come to a close at the Madison Square Garden. In a very neat booth were displayed his full line of improved gas lighting apparatus and notably his Bartholdi automatic gas burner, of which there are now over 100,000 in use.

MR. FRED. M. LOCKE, of Victor, N. Y., has just been advised that his patent triple petticoat china insulators and steel pins have been in use for two months giving splendid satisfaction on the power transmision line between Newcastle and Sacramento, Cal., carrying 1,000 horse-power 30 miles at 15,000 volts. There is not the slightest sign of leakage on the line.

TUCKER ELECTRIC CONSTRUCTION COMPANY., Whitehall street, report a satisfactory local trade. Among the recent buildings installed by this firm are the New York Life on Broadway, and nearly all the buildings now in course of construction on University Heights.

MR. W. McCULLOUGH, who has been looking after the Canadian General Electric Company's interests for the past three years in the West, is now representing Mr. Hugo Reisinger, No. 38 Beaver street, New York, sole importer of the celebrated "Electra" highest grade Nuernberg carbons. While the Canadian General Electric Company regret parting with one who has always been to the front where anything electrical was required, Mr. Reisinger is to be congratulated on his good fortune in securing the services of such an energetic salesman. His numerous friends will be pleased to learn of his new connection and will wish him much success in his new position.

ELECTRIC LIGHTING

REPORT TO THE SPECIAL INVESTIGATING COMMITTEE ON COMMERCIAL ELECTRIC LIGHTING, SOUTH NORWALK, CONN.

BY A. E. WINCHESTER, E. E.
(Member of the Board of Electric Light Commissioners.)

THE undersigned member of your committee, selected by you to obtain information upon the subject of producing and supplying electric current for commercial lighting from the city's electric works, begs to submit this report as the result of his investigations.

Municipalities have been engaged in supplying water for public and private needs since the date of civilization, and have maintained their water departments from a revenue collected for water privileges. Public lighting has also been supplied by public corporations from the earliest days, and the time since private companies first attempted to handle these two great public necessities, dates back but little more than a century, but, during that time up to within a few years ago, privately owned works for supplying water and light increased so rapidly that municipalities owning such works are now in the minority, especially in this country, and especially so with regard to publicly owned lighting plants. When electricity came into practical use, however, municipal electric light plants began to appear in England and Europe, and now in the former country municipalities equipped with their own electric light plants are in the majority. In this country we have no such showing, but to indicate that the idea is growing, it may be interesting to point out the fact that ten or a dozen years ago such a thing as a municipal electric light plant was almost unknown, and when finally some cities were bold enough to try the experiment, the overture was much criticised and looked upon with no little distrust; however, about two years ago statistics showed that the municipal electric light plants had reached the number of 150, and to-day we have in the United States over 300 such plants, an increase of 100 per cent. in about two years, nearly all of which are selling electric current for commercial consumption as well as supplying it for public lighting, affording with but rare exceptions most gratifying results in the way of economy and satisfaction to the localities possessing them, as is attested by the large number of answers received to some 200 letters of inquiry that I sent out to every municipal electric light plant that could be reached in this country. There is now hardly to be found a city of any importance not already possessed of such a plant but what is either building one or conducting investigations to that end, except in very large cities having large, well-managed private electric light plants which are conducted on broad principles, fair and satisfactory to the people, supplying excellent service at low rates, such as we find in New York, Brooklyn, Philadelphia, Boston, Chicago, San Francisco, and such places, which give the citizens a service as good as can be had. The small cities are the ones that suffer, containing miserable, cheap private plants that are run cheaply and charge high rates for poor service.

In the columns of electrical periodicals are constantly to be found news items describing new municipal plants being built in just such places, small cities as a rule, though but few of these papers dare to encourage or defend such undertakings, generally lamenting the fact editorially, and endeavor to persuade municipalities to give up the idea as one that they allege can only result in failure, referring with great stress to a few such instances which have been worn threadbare by editors' pens. If they can get their hands upon a good report of a municipal plant, they assume the right to distort it so that it reads the way they would have it; this is probably because the electrical journals are largely dependent upon and stand in fear of the great army of small private plant owners, who naturally welcome any means condemnatory of municipal plants for the best of reasons; they are not in the business for love or to advance public economy, and cannot live with a competitor in the field which is only intended to be self-sustaining and which places them in an unfair light by comparison, when it is considered that they must and should make a profit or go out of business.

The cost of lighting the streets of our city from its own plant, though known to be much lower than the same class of service would be if supplied by a private company, amounts to nearly 20% of the city's taxes, including the interest on the investment and the chargeable depreciation against the machinery. It is therefore obvious that any reduction in this item of expense would be of benefit to the taxpayer. For a private corporation to undertake to run a business which would only be self-sustaining at best and likely to run at a loss would be folly indeed, but when an institution is conducted by the public for the purpose of supplying a costly public necessity, such as water or light, the difference is at once apparent, for it will be seen at a glance that if it can by any means be made to contribute anything toward reducing its cost of maintenance, even though small at first, a certain source of public economy has been reached. There is also another reason favorable to a municipal plant. Inasmuch as it would not be intended to turn out dividends, it would be possible for it to supply the demands for commercial lighting low enough to be within the reach of many who could not otherwise afford to use it, and the consumer would not only have the advantage of low lighting rates, but would also enjoy a lower rate of taxation. This being so, the proportion of consumers would naturally be greater than if the supply was derived from a private plant at ordinary profit earning prices, and it is also true that the proportional cost of production would become less as the demand increased.

Municipal plants have two dangerous enemies to contest against. The first is, political corruption—which though more often exposed is undoubtedly no worse or more frequent than the dishonest intrigues employed among some men in conducting private business enterprises, but the second and most difficult to deal with is the combined influence of the owners of small private plants, usually controlled by trusts. The first, if allowed to obtain a foothold, is bound to result in failure in the conduct of any public institution, but the people have the means at hand to prevent any such condition if they do their public duty and are careful whom they place in office; if not, they deserve to be imposed upon. There is no good reason why a public business cannot be managed with as great care as a private one, and it is a shameful assertion for any one to say that it cannot. All public officers are not rascals any more than are the heads of private concerns.

The exceptional instances of corruption and mismanagement are what are usually magnified and waved before the public by the second enemy, the owner of the small private plant as a horrible example of what he wishes to prevent them from following. He has even used his influence, money if you will, with such telling effect before the Legislatures of nearly every State in the Union as to have laws passed heaping such rigid restrictions upon municipalities that almost prohibit them from establishing electric light plants, but even so, they are constantly increasing. In his arguments, he appeals for the capital invested in the private local plant, which nine times out of ten is owned by outside capital that has no other interest in local affairs than as a means of revenue. He calls our attention to the fact that the private plant pays taxes and water rent, the total amount of which at most would form but a small percentage of the saving otherwise to be derived from a plant owned by the people in which every taxpayer would be a shareholder and receive his dividends in reduced taxes. The owner of the private plant also knows but too well that each municipal plant that springs into existence becomes widely known and is carefully watched by other municipalities far and near, and if successful the idea will spread as it has already, to the detriment of one of the deepest-rooted monopolies of the times.

I have given this subject a most searching and prolonged study, having gleaned every source for information that has reached my notice, including an extensive correspondence with Mayors and public officials of localities having municipal plants, but as it would consume too much space to give in full the answers to my queries, I will quote such facts as will be of use to this report, as follows, from municipal plants returns:

ANALYSIS OF MUNICIPAL PLANT REPORTS.

NEWARK, DEL. No street lamps. Five hundred 16-candle-power commercial incandescent lamps in service. Lights and water supplied from same department. Operating expenses equally divided. Interest on investment included in expenses, depreciation excluded:

Income of plant, per year	$3,143.75
Expenses of plant, per year	2,617.91
Income over expenses	$525.84

Remarks of Manager: "I myself say that where the water and electric light plants are operated together they are a success for municipal plants with proper management. We have only a population of about 1,500."—(Signed) A. Homewood, Superintendent and Manager.

GRIFFIN, GA.—Fifty 2,000 candle-power arc lamps on streets; 1,500 10 and 16 candle-power commercial incandescent lamps in service. Light and water supplied from same department. Division of expenses estimated. Interest on investment and depreciation included in expenses.

Income of plant, per year	$15,000.00
Expenses, per year	8,000.00
Income over expenses	$7,000.00

Remarks by Superintendent: "This plant is just in its second year, but I believe in municipal plants if run on business principles and kept out of politics."—(Signed) W. Key Howard, Superintendent.

CRAWFORDSVILLE, IND.—One hundred and forty-four 2,000 candle-power arc lamps on streets; 2,600 16, 25, 32 and 50 candle-power commercial incandescent lamps in service. Electric light plant independent of any other department. Interest and insurance included in expenses, depreciation not stated.

Expenses of plant, per year	$13,000.00
Income, per year	7,000.00
Expenses over income	$6,000.00

Remarks by Superintendent: "It's the only thing a city should do."—(Signed) Fred S. Brown, Superintendent.

LOGANSPORT, IND.—One hundred and fifty-seven 2,000-candle-power arc lamps in streets, 30 2,000-candle-power commercial arc lamps, 4,000 16-candle-power commercial incandescent lamps in service. Electric light plant independent of any other department. Bonds paid, no interest charged. Depreciation not included in expenses.

Income of plant, per year	$15,000,00
Expenses, per year	12,000.00
Income over expenses	$3,000.00

Remarks by Chairman:"My opinion is that every city should own and operate her own electric light plant. Our income from last year's private lighting was half the entire operating expenses. This year the income from this source will more than pay the entire running expenses, lighting our streets for nothing."—(Signed) S. B. Boyer, Chairman Electric Light Committe.

KENDALLVILLE, IND.—Forty-three 2,-000-candle-power arc lamps in streets, 17 2,000-candle-power commercial arc lamps in service, no incandescent lamps. Lights and water supplied from same department. Division of expenses estimated. Interest on investment included in expense; depreciation not stated.

Expenses of plant, per year	$3,000.00
Income of plant, per year	1,000.00
Expenses over income	$2,000.00

Remarks by Superintendent: "For a city to operate its own water works system and also electric lighting is the proper thing, but a detriment to those wishing to speculate on city franchises."—(Signed) W. S. Osborne, Superintendent.

GOSHEN, IND.—City does only street lighting. Remarks by Chairman: "We do no commercial lighting; we think the only way to light a city is for the city to own her electric light plant."—(Signed) Edward Kelly, Chairman Water Committee.

MUNCIE, IND.—City does only street lighting. Remarks by Superintendent: "If municipal electric light plants are kept out of politics, they can be economically run. I think as a general rule they are unsatisfactory."—(Signed) W. F. Warner, Superintendent.

CHARITON, IOWA.—One hundred and ten 32-candle-power incandescent lamps in streets, 1,180 16-candle-power incandescent commercial lamps in service. Electric light plant independent of any other department. Interest on investment and depreciation not included in expenses.

Income of plant, per year	$6,000.00
Expenses of plant, per year	5,500.00
Income over expenses	$500.00

Remarks by City Clerk: "I am a strong believer in municipal ownership of its own electric light and water works."—(Signed) Don. E. Lewis, City Clerk.

CITY OF WINTERSET, PA.—Four 1,000 candle-power arc lamps in streets, 130 16-candle-power incandescent lamps in streets, 30 1,000-candle-power commercial arc lamps in service. Electric light plant independent of any other department. Interest and sinking fund included in expenses.

Income of plant, per year	$4,500.00
Expenses of plant, per year	3,600.00
Income over expenses	$900.00

Remarks by Superintendent: "My opinion of municipal lighting; it will pay in any town providing you put in good apparatus and then have a good man to run it and take care of it."—(Signed) S. O. Klein, Superintendent.

ATLANTIC, IOWA.—One hundred and fifty-six 30-candle-power incandescent lamps in streets, 3,000 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and insurance included in expenses, depreciation not stated.

Income of plant, per year	$12,600.00
Expenses of plant per year	8,300.00
Income over expenses	$4,300.00

Remarks by Mayor: "We are making money out of ours, but get plenty of capacity in engines, etc. Our plant is quite satisfactory."—(Signed) J. B. Jones, Mayor.

LISBON, IOWA.—Fourteen 2,000-candle-power arc lamps in streets, 8 2,000-candle-power arc lamps in commercial service, 500 16-candle-power incandescent lamps in commercial service, 1,400 16-candle-power commercial incandescent lamps in service. Electric light plant independent of any other department. No division of expenses. Interest and depreciation not included in expenses.

Expenses of plant, per year	$3,125.00
Income of plant, per year	3,000.00
Expenses over income	$125.00

Remarks by Mayor and Superintendent: "I think the city should in each case own its plant and services on streets, and supply its citizens at a normal cost. A more foolish thing a city could not well do than give away a franchise for a lighting plant. Can be managed economically by single superintendent at a small cost."—(Signed) W. H. Runkle, Mayor and Superintendent.

WINTON, IOWA.—By a mistake, my letter of inquiry was sent to the owner of a local plant instead of the municipal plant, but as the letter is a good one, I quote it in full: "Dear Sir: You do me and my business too much honor. Though I made careful reports of the workings of my plant, I had to put all the money I got out of it right back into it, and then the city refused to give me street lighting, and put in a plant of its own and cut commercial lighting from 25 per cent. to 60 per cent., so that it run me in debt to run the plant. So I am shut down and trying to sell out for 25 cents on a dollar, as a whole, and having one of the finest dynamos ever run, a Westinghouse, 500 lights, upon which we run 500 to 700 regularly. Yours, etc."—(Signed) C. E. Wilcox.

FAIRFIELD, IOWA.—City does only street lighting. Remarks by Mayor: In speaking of the plant he says: "It is operated along with our water works system, and we think it a success."—(Signed) A. W. Jaques, Mayor.

SANDWICH, ILL.—The Mayor writes: "I am very glad to hear that our plant has as good a reputation as it has, and is heard from in the far away State of Connecticut. I will say that we have an elegant plant and water works, which we run in connection. I will have your blanks filled out properly by our City Clerk and forwarded to you at once, hoping that they may be of advantage to you in your investigations throughout the country."—(Signed) A. G. White, Mayor.

ST. CHARLES, ILL.—Two hundred and twelve 30-candle-power incandescent lamps in streets, 600 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses.

Expenses of plant, per year	$2,771.68
Income of plant, per year	2,622.25
Expenses over income	$149.43

Remarks by City Clerk: "We are well pleased with ours. Would be pleased to have you call."—(Signed) P. Hempstead, City Clerk.

METROPOLIS, ILL.—Thirty-five 2,000-candle-power arc lamps in streets, 700 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. No division of expenses. Interest and depreciation not stated.

Income of plant, per year	$3,812.75
Expenses of plant, per year	3,812.75

Income and expenses balance.

Remarks by Superintendent: "Municipal plants are not as economical as they should be, and are not managed as they should be. It seems as though there is no one to go ahead and carry out the things as they should be; in other words, business is done too low."—(Signed) Henry Shelton, Superintendent.

BENTON, ILL.—Fourteen 1,200-candle-power arc lamps in streets, 650 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not stated.

Income of plant, per year	$2,400.00
Expenses of plant, per year	1,300.00
Income over expenses	$1,100.00

Remarks by Superintendent: "Plant is owned by village; our lights cost nothing."—(Signed) C. H. Bassett, Superintendent.

HERINGTON, KAN.—Ten 1,200 candle-power arc lamps in streets, 10 16-candle-power incandescent lamps in streets, 9 1,200-candle-power arc lamps in commercial service, 400 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Division of expenses, 75 per cent. charged to lights and 25 per cent. to water. Interest and depreciation not included in expenses.

Income of plant, per year	$4,200.00
Expenses of plant, per year	4,000.00
Income over expenses	$200.00

Remarks by Superintendent: "Get good men and then keep them; don't be changing men each year; a good man can make a success if given time, but a good man can't do much in one year."—(Signed) I. S. Brundage, Superintendent.

TECUMSEH, NEB.—Seventy-six 16-candle-power incandescent lamps in streets, 422 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Division of expenses proportioned. Interest and depreciation not included in expenses.

Expenses of plant, per year	$1,853.77
Income of plant, per year	1,160.17
Expenses over income	$693.60

Remarks by Mayor: "I think our plant is not of sufficient capacity for the work we have for it to do, and this makes much more expense for us than it would otherwise be."—(Signed) P. H. Hopkins, Mayor.

BANGOR, ME.—City does only street lighting. Remarks by City Clerk: "Municipal lighting has proved very satisfactory to us. We have saved annually about $4,000.00 in expense of lighting over our old gas system, with much better lighted streets."—(Signed) Victor Brell, City Clerk.

LEWISTON, ME.—City does only street lighting. Remarks by Superintendent: "Buy the best apparatus in market, employ good, faithful help, and see that they take good care of apparatus; if they don't attend to business give them the bounce and hire some one who will."—(Signed) Asa T. Green, Superintendent.

MIDDLEBORO, MASS.—One hundred and eight 1,200-candle-power arc lamps in streets, 4 1,200-candle-power arc lamps in commercial service, 1,400 incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation included in expenses.

Expenses of plant, per year	$19,039.88
Income of plant, per year	12,000.00
Expenses over income	$7,039.88

Remarks by Manager: "My opinion after two years' experience in municipal lighting is, that it pays. My experience as Manager for the Thomson-Houston Company is, they make it pay."—(Signed) John W. Main, Manager.

NORTH ATTLEBORO, MASS.—Five hundred and eighty-four 32-candle-power incandescent lamps in streets, 2,158 12 and 16 candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Expenses charged half to lights and half to water. Interest and depreciation not stated.

Expenses of plant, per year	$6,704.04
Income of plant, per year	3,679.60
Expenses over income	$3,024.44

Remarks by Manager: "So far as I can judge, municipal plants ought to and can be run with better advantage than private plants."—(Signed) W. P. Whitmore, Manager.

PEABODY, MASS.—One hundred and fifty-seven 1,200-candle-power arc lamps in streets. Number of commercial arc and incandescent lamps in service not stated. Electric plant independent of any other department. Interest and depreciation in doubt.

Expenses of plant, per year	$11,439.55
Income of plant, per year	4,960.69
Expenses over income	$6,478.86

Manager of plant is P. L. Winchester.

BAINTREE, MASS.—Ninety-two 1,200-candle-power arc lamps in streets, 109 25-candle-power incandescent lamps in streets, 3,800 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest reserve for sinking fund, insurance and water rent included in expenses.

Expenses of plant, per year	$10,500.00
Income of plant, per year	5,600.00
Expenses over income	$4,900.00

Remarks by Superintendent: "Have been connected as constructing engineer of this and three other plants (municipal) in this State, and can truthfully say that properly managed we can give better service for less money than any commercial plant I know of."—(Signed) J. Frank Perry, Superintendent.

SAVANNAH, MO.—Twenty-six 1,200-candle-power arc lamps in streets, 550 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses.

Income of plant, per year	$3,049.98
Expenses of plant, per year	2,966.02
Income over expenses	$83.96

Remarks by Superintendent: "Our plant has been a success thus far, and the citizens are well pleased with it. Municipal electric lighting is all right if you can keep politics out of it."—(Signed) B. S. Cheney, Superintendent.

SALISBURY, MO.—Twenty 2,000-candle-power arc lamps in streets, 20 2,000-candle-power arc lamps in commercial service, 540 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses.

Expenses of plant, per year	$2,840.00
Income of plant, per year	2,000.00
Expenses over income	$840.00

Remarks by ex-Mayor and electrician: "From my experience, I would advise that the plant be owned and operated by the city."—(Signed) D. R. Patterson, ex-Mayor; W. A. Howard, Electrician.

BRUNSWICK, MO.—Twenty 2,000-candle-power arc lamps in streets, 290 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Interest and depreciation not included in expenses.

Income of plant, per year	$2,016.65
Expenses of plant, per year	1,983.40
Income over expenses	$33.25

Manager is C. E. Boston.

ALEXANDRIA, MINN.—Eleven 1,200-candle-power arc lamps in streets, 600 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Interest and depreciation not included in expenses. No division of expenses made.

Income of plant, per year	$4,100.00
Expenses of plant, per year	3,500.00
Income over expenses	$600.00

Remarks by Chief Engineer: "Employ a competent Superintendent, with ample powers as such during good behavior. Keep out of politics, and it should be cheaper than private corporation service."—(Signed) C. A. Johnson, Chief Engineer.

WASECA, MINN.—Thirty-three 2,000-candle-power arc lamps in streets, 40 2,000-candle-power arc lamps in commercial service, 800 16-candle-power incandescent lamps in commercial service. Light and water supplied from same department. Plant not run long enough to give figures covering income and expenses.

Remarks by Mayor: "Our plant is so new that we have not fully systematized it as yet, so are unable to report any funds. We are well satisfied, however, and believe in municipal lighting."—(Signed) D. S. Cummings, Mayor.

WELLS, MINN.—Six 1,200-candle-power arc lamps in streets, 35 24-candle-power incandescent lamps in streets, 16 1,200-candle-power arc lamps in commercial service. 650 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Interest and depreciation not included in expenses. Division of expenses not stated.

Expenses of plant, per year	$4,000.00
Income of plant, per year	3,500.00
Expenses over income	$500.00

Remarks by Superintendent: "I do not believe in municipal ownership of electric plants, as too much political influence is brought to bear on it, and plant suffers from it both as to management and economy."—(Signed) A. C. Johnson, Superintendent.

LUVERNE, MINN.—Sixteen 2,000-candle-power arc lamps in streets, 19 2,000-candle-power arc lamps in commercial service, 1,000 16-candle-power incandescent lamps in commercial service. Light and water supplied from same department. Division of expenses, two-thirds charged to lights and one-third to water. Interest and depreciation not included in expenses.

Income of plant, per year	$4,800.00
Expenses of plant, per year	4,000.00
Income over expenses	$800.00

Remarks by Recorder: "The village is well satisfied both with results and service."—(Signed) E. S. Rogers, Village Recorder.

FULDA, MINN.—Fifty 32-candle-power incandescent lamps in streets, 400 16-candle-power incandescent lamps in commerical service. Electric plant independent of any other department. Interest and depreciation not stated.

Income of plant, per year	$2,500.00
Expenses of plant, per year	2,200.00
Income over expenses	$300.00

Remarks by Recorder: "Municipal electric light plants are the only economical plants in existence as the consumer only pays the safe actual cost of what he consumes."—(Signed) Robert Hyslop, Village Recorder.

ST. PETER, MINN.—Forty-four 2,000-candle-power arc lamps in streets, 500 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses.

Income of plant, per year	$5,193.15
Expenses of plant, per year	4,269.20
Income over expenses	$923.95

Remarks by Clerk: "Is the most satisfactory to people in general."—(Signed) H. T. Slater, Clerk.

ROCHESTER, MINN.—Eighty-one 2,000-candle-power arc lamps in streets, 38 2,000-candle-power arc lamps in commercial service, 1,500 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses.

Expenses of plant, per year	$5,600.00
Income of plant, per year	5,000.00
Expenses over income	$600.00

Remarks by Superintendent: "Much better than if run by private parties, as it is run on a more liberal plan, enabling the employé to give better service, not feeling hampered by excessive economy."—(Signed) W. G. Rowen, Superintendent.

LANSING, MICH.—One hundred and sixteen 2,000-candle-power arc lamps in streets, 60 2,000-candle-power arc lamps in commercial service. Number of incandescent lamps in commercial service not stated. Electric plant independent of any other department. Interest included in expenses, depreciation excluded.

Income of plant, per year	$27,000.00
Expenses of plant, per year	15,000.00
Income over expenses	$12,000.00

Remarks by Secretary: "I bélieve that if municipal authorities will manifest the same zeal in protecting its own plant that is usually shown in protecting a franchise granted to a private corporation, that good results in service and economy will follow; of course a careful management is necessary."—(Signed) Daniel Barringer, Secretary.

MARSHALL, MICH.—Eighty-one 2,000-candle-power arc lamps in streets, 35 2,000-candle-power arc lamps in commercial service, 1,500 16-candle-power incandescent lamps in commercial service. Electric light plant independent of any other department. Interest not included in expenses. Depreciation not stated.

Income of plant, per year	$4,000.00
Expenses of plant, per year	3,500.00
Income over expenses	$500.00

Remarks by Superintendent: "Our plant has been very successful so far; we now pay all running expenses, and the city only has to pay interest at 5 per cent. on bonds and pay bonds that become due each year for its lighting."—(Signed) P. S. Jay, Superintendent.

KALAMAZOO, MICH.—City does only street lighting. Remarks by Superintendent: "A municipal plant operated by manager or superintendent with complete authority can be operated very economically and to a great saving to the city."—(Signed) H. C. Hoagland, Superintendent.

COLD WATER, MICH.—Seventy-seven 2,000-candle-power arc lamps in streets, 11 16-candle-power incandescent lamps in streets, 20 2,000-candle-power arc lamps in commercial service. Number of incandescent lamps in commercial service not stated. Lights and water supplied from same department. Interest included in expenses, depreciation excluded. No division of expenses.

Income of plant, per year	$21,868.65
Expenses of plant, per year	18,804.87
Income over expenses	$3,063.78

Remarks by Superintendent: "For a city of this size (5,500), in connection with water works, I think it advisable for a city to own its light plant and to do commercial lighting. Without water department, it depends on size of city, competition, etc."—(Signed) L. A. Dillingham, Superintendent.

HOLLAND, MICH.—Fifty 2,000-candle-power arc lamps in streets, 15 2,000-candle-power arc lamps in commercial service, 2,550 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Interest included in expenses, depreciation excluded. Division of expenses estimated.

Income of plant, per year	$21,910.46
Expenses of plant, per year	21,551.49
Income over expenses	$358.97

Remarks by President: "So far as my experience goes, I do not particularly favor a city attempting to do any more than public lighting, but see no particular objection to a city or town of moderate size, say, 20,000 inhabitants, or less, doing commercial lighting. As to larger cities, I cannot, of course, speak from experience, but am inclined to the opinion that there would be a chance for corruption and appointment of favorites for political influence, etc."—(Signed) C. J. De Roo, President, Board of Public Works.

PAW PAW, MICH.—Thirty-two 2,000-candle-power arc lamps in streets, 24 1,200-candle-power arc lamps in commercial service, 600 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses.

Income of plant, per year	$2,400.00
Expenses of plant, per year	1,500.00
Income over expenses	$900.00

(Signed) William H. Mason, Village Clerk.

EVART, MICH.—Sixteen 2,000-candle-power arc lamps in streets, 400 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Expenses equally divided. Interest and depreciation included in expenses.

Expenses of plant, per year	$1,500.00
Income of plant, per year	1,200.00
Expenses over income	$300.00

Remarks by Chairman: "We are well satisfied with our plant."—(Signed) C. E. Bill, Chairman Electric Light Committee.

NILES, MICH.—Seventy-three 2,000-candle-power arc lamps in streets, 2 32-candle-power incandescent lamps in streets, 27 2,000-candle-power arc lamps in commercial service. 1,600 16 and 30 candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Interest and depreciation not included in expenses. Expenses equally divided.

Income of plant, per year	$8,000.00
Expenses of plant, per year	5,000.00
Income over expenses	$3,000.00

Remarks by Superintendent: "These plants are now owned by the city, and being run by water power, and both together bring the cost of hydrants at about $30.00 per year and street arc lamps at $40 per year for total cost as named above."—(Signed) M. A. Earl, Superintendent.

HAMILTON, N. Y.—Fifty 1,200-candle-power arc lamps in streets, 1,500 16 and 32 candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Plant has not been run long enough to determine amount of income and expenses. Remarks by Superintendent: "Our plant has been in operation less than ten months. So far as we can determine now, it is successful and profitable. The people are well pleased."—(Signed) E. D. Kingsbury, Superintendent.

DUNKIRK, N. Y.—Quotation from letter: "I am very sorry I cannot give you information on the matter of which you inquire. We are situated very much as you are, having street arc lighting only. We are about taking action to extend our system to incandescent lighting also."—(Signed) R. L. Cary, President Water Board.

WESTFIELD, N. Y.—Seventy-two 2,000-candle-power arc lamps in streets, 450 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation included in expenses.

Expenses of plant, per year	$5,000.00
Income of plant, per year	1,500.00
Expenses over income	$3,500

Remarks by Superintendent: "I think there is no question about municipal plants if they are properly managed and no mistakes made in starting in, as to machinery and rates, contracts, etc."—(Signed) J. G. Finlay, Superintendent.

MADISON, N. J.—Four hundred and twenty 30-candle-power incandescent lamps in streets, 1,800 16-candle-power incandescent lamps in commercial service. Lights and water supplied from same department. Division of expenses proportioned. Interest included in expenses, depreciation excluded. Income and expenses taken from report.

Income of plant, per year	$10,404.80
Expenses of plant, per year	8,784.72
Income over expenses	$1,620.08

Remarks by Manager: "Our style of plant is very satisfactory for scattered population like ours."—(Signed) W. M. Bell, Manager.

REIDSVILLE, N. C.—Twenty-eight 1,200-candle-power arc lamps in streets, 365 16-candle-power incandescent lamps in commercial service. Electric plant independent from any other department. Interest and depreciation not included in expenses.

Income of plant, per year	$7,500.00
Expenses of plant, per year	3,800.00
Income over expenses	$3,700.00

(Signed) John S. Pannill, Superintendent.

ASHTABULA, OHIO.—Sixty-eight 2,000-candle-power arc lamps in streets, 4,008 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and insurance included in expenses, depreciation excluded.

Income of plant, per year	$14,434.00
Expenses of plant, per year	12,267.00
Income over expenses	$2,167.00

Figures taken from report of Superintendent J. A. Manning.

JACKSON, OHIO.—Forty 2,000-candle-power arc lamps in streets, 35 1,200-candle-power arc lamps in commercial service, 1,213 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses.

Income of plant, per year	$7,000.00
Expenses of plant, per year	4,000.00
Income over expenses	$3,000.00

Remarks by Electrician: "Bad. This plant is run by a committee from Council, which is changed every year; so we get new management every year that does not become acquainted with the work until changed; the attention is not paid to details as would be by a private company."—(Signed) George D. Hoop, Electrician.

OXFORD, OHIO.—Forty-two 2,000-candle-power arc lamps in streets, 700 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses.

Income of plant per year	$7,000.00
Expenses of plant, per year	4,000.00
Income over expenses	$3,000.00

Remarks by Trustee: "We believe they can be successfully operated in small towns, say up to 3,000 or 4,000 people, but not in larger, on account of political affairs being so often mixed up with them."—(Signed) S. H. Allen, Trustee.

WELLSTON, OHIO.—Fifty-six 1,200-candle-power arc lamps in streets, 2 1,200-candle-power arc lamps in commercial service, 900 16-candle-power incandescent lamps in commercial service. Light and water supplied from same department. Two-thirds of expenses charged to lights, one-third to water. Interest and depreciation not included in expenses.

Income of plant, per year	$4,000.00
Expenses of plant, per year	3,600.00
Income over expenses	$400.00

Remarks by Secretary: "Believe it pays any city to own its light plant, being cheaper, gives better satisfaction, but probably more difficult management."—(Signed) J. J. Bennett, Secretary.

MARIETTA, OHIO.—City does only street lighting. Remarks by Superintendent: "Our plant has so far cost us about $18,000.00. The City Council are now considering plans to enlarge it to 300 lights. The plant has been overloaded for the past three years. We have no commercial plant in this city. Our electric street railroad company having a franchise to put in a plant for commercial purposes. The street railroad company proposed to buy the city plant at $15,000 cash and make street lighting at $65.00 per light. No sale. No politics, and keep an employé as long as he does his duty, will insure success in any business."—(Signed) Thomas Hancock, Superintendent.

DE GRAFF, OHIO.—Twenty-nine 2,000-candle-power arc lamps in streets, 1,000 16-candle-power incandescent lamps in commercial service. Electric light department run jointly with fire department. Interest and depreciation not included in expenses.

Income of plant, per year	$4,500.00
Expenses of plant, per year	4,000.00
Income over expenses	$500.00

Remarks by ex-Manager: "Have had three years' experience in managing municipal plants and think they can be made a success of, although in many cases they are not, especially if controlled by a whole council instead of a committee of the council, for in nine cases out of ten they will put their judgment up against a man of years of experience in the management of plants."—(Signed) Fred. Rea, ex-Manager.

GALION, OHIO.—Eighty-seven 2,000-candle-power arc lamps in streets, 34 2,000-candle-power arc lamps in commercial service, 900 16, 32 and 50-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation not included in expenses. Superintendent has not run plant long enough to give yearly figures, but says the receipts for February, March and April amounted to $1,106.24. In speaking on the subject of municipal plants the Superintendent says: "Good because cheaper and plant can be run to suit the people without contracts, and changed when desired, and the larger the plant the cheaper the light can be furnished."—(Signed) W. A. Ross, Superintendent.

WILMINGTON, OHIO.—Eighty-six 2,000-candle-power arc lamps in streets, 49 2,000-candle-power arc lamps in commercial service, 700 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation included in expenses.

Income of plant, per year	$3,250.00
Expenses of plant, per year	3,200.00
Income over expenses	$50.00

Remarks by Superintendent: "In my experience, no plant should be run by any municipal corporation for there are so many that want to be boss and too many free lights."—(Signed) H. C. Taylor, Superintendent.

ALLEGHENY, PA.—City does only street lighting. Remarks by Superintendent: "As to municipal ownership, I believe it to be the proper thing, even admitting that there would be no saving financially. Your plant being in your own hands, you may do with it as you see fit, and are free from the incessant troubles due to dealing with corporations. In addition to the above our city saves not less than $25,000 annually comparing with prices paid by our sister city Pittsburg."—(Signed) D. Hunter, Jr., Superintendent Bureau Public Works.

QUAKERTOWN, PA.—Forty 1,200-candle-power arc lamps in streets, 800 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Interest and depreciation included in expenses.

Expenses of plant, per year	$5,272.00
Income of plant, per year	4,320.00
Expenses over income	$952.00

Remarks by Superintendent: "Municipal electric plants are and will be a success if politics can be kept away from them. We have no trouble here. The town of Quakertown would not sell the plant for any money."—(Signed) Gottlieb Frey, Superintendent.

SCHUYLKILL HAVEN, PA.—Forty 2,000-candle-power arc lamps in streets, 500 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Usually high interest and depreciation included in expenses.

Expenses of plant, per year	$4,500.00
Income of plant, per year	2,000.00
Expenses over income	$2,500.00

Remarks by Superintendent: "Where a municipal plant is run with the same care and business methods that are used by corporations, it is bound to save the municipality the profits which go to the corporations. It should be run without political interference or dictation and left in the hands of a competent superintendent."—(Signed) E. N. Hyde, Superintendent.

WEST NEWTON, PA.—Thirty-two 2,000-candle-power arc lamps on streets, 1,000 16-candle-power incandescent lamps in commercial service. Electric plant independent of any other department. Unusually high interest and depreciation included in expenses.

Income of plant, per year	$4,200.00
Expenses of plant, per year	3,400.00
Income over expenses	$1,800.00

Remarks by Superintendent: "I think that a municipal plant, if properly managed, is the cheapest way to light up a city or town. Last year our plant paid the interest on the money invested."—(Signed) A. R. McMillan, Superintendent.

From the numerous replies received to my inquiries, I have selected the foregoing without discrimination and believe they will convey a fair idea as to merits and demerits of the subject under consideration from the most reliable sources of information, the results of actual experience.

A preliminary canvass of the probable commercial lighting territory of South Norwalk was made and it was found that a commercial plant having a capacity of about 2,000 16-candle-power lamps would be of the proper size to meet the probable demand at present and that it could be erected in the space provided for such purpose in the building of the city's electric works without any extensive alterations to the present plant and but few other changes. The present city poles would be sufficient size except in a few instances for all additional electrical conductors that would be necessary. After carefully considering the various systems in use for generating and supplying electric current, the one selected upon which I have based my estimate is known as the direct low tension system on the two or three wire principle, employing 110 or 220 volts at the lamps, as it would not only be the least costly to maintain, but would be free from danger to life and would supply a current equally suitable for motors, arc or incandescent lamps. The narrow limits of our city and the condensed lighting territory together with the nearness of the generating station to the center of distribution makes the system described the most suitable and practical, whereas in a scattered district it would be impracticable, owing to the excessive cost of construction for long distance transmission.

The cost of constructing the system described above, having a normal capacity of 2,000 16-candle-power incandescent electric lamps would be as follows:

ESTIMATE OF CONSTRUCTION.

Steam Plant.—	
1 Improved steel smoke stack,	
1 Foundation for smoke stack,	
1 Smoke flue and connections,	
1 Horizontal tubular boiler 72" x 16',	
1 Boiler setting and furnace,	
2 Automatic high speed engines,	
2 Engine and dynamo foundations,	
Piping connections, alterations, etc.	
Cost of steam plant	$7,150.00
Electric Plant.—	
2 50-kilowatt or 4 25 kilowatt direct connected M. generators,	
1 switchboard and electric appliances,	
Feeders, mains and line construction,	
Cost of electric plant	$8,000.00
Labor, freight, carting, etc.,	
Changes and alterations,	
Labor, engineering, planning and specifications,	
Freight, carting and contingencies,	
Cost of labor, etc.	$2,850.00
Total cost of plant in running order	$18,000.00

ESTIMATE OF YEARLY RUNNING EXPENSES.

Cost of operating the city's present municipal street lighting plant, including interest and depreciation as shown in last report of Oct. 13, 1895		$5,902.25
Cost of operating proposed plant:		
Salaries for additional force	$2,160.00	
Fuel	2,800.00	
Cylinder, engine and dynamo oil and waste	205.00	
Interest, depreciation, repairs, etc.	2,380.00—	7,545.00
Total yearly expenses		$13,447.25

Estimated income of plant, taken from a conservative canvass of the lighting territory of South Norwalk, figured at a very low charge, gives the following results:

Income for commercial incandescent and arc lighting, per year	$10,923.12

RECAPITULATION.

Total yearly expenses	$13,447.25
Total yearly income	10,923.12
Expenses over income	$2,524.13

It will thus be seen by these figures that the cost to the city for lighting its streets which, according to the last report, was $5,902.25, would be reduced to $2,524.13, leaving a net saving to the city of $3,378.12.

As the cost of operation is fixed at a conservative high figure and the source of income is based on a comparatively small proportion of the probable number of consumers of electric current at a very low rate, it is believed that the actual income resulting from practical experience would represent a much larger amount than above stated, and the income to be derived from commercial lighting would undoubtedly within a comparatively short time be sufficient to make the plant self-sustaining, thus reducing the cost of lighting the city's streets to nothing.

In the belief that I have fulfilled the mission assigned me, I take pleasure in submitting the foregoing report for your consideration.

The above report is based upon the blanks sent out by Mr. Winchester, asking for information in regard to all the details of the plant, its operation and its results. In addition to the report, Mr. Winchester furnishes us with the accompanying table in which he has drawn up a comparison of the conditions of a private and a municipal plant, as relative to the question of taxation and the presumable saving to the citizens:

BRIEF FACTS FOR COMPARISON BETWEEN A PRIVATE AND MUNICIPAL PLANT UNDER SIMILAR CONDITIONS. TAKEN FROM 1896 REPORT OF SOUTH NORWALK, CONN., MUNICIPAL PLANT.

PRIVATE PLANT.

Owned by stock company, directors elected without pay by shareholders (as is the custom of a plant of this size), from their own number—

Capital invested		$22,500.00
[1] Income per year, 100 arc lamps, at $70		7,000.00
Expenses per year.—		
New construction	$143.22	
Repairs	246.11	
Tools and equipment	13.42	
Running expenses	1,723.30	
Salaries	2,400.00	
Taxes	192.00	
Water rent	75.00	
[2] Depreciation on $15,576.38 at 5 per cent	778.82	
Total expenses		$ 5,571.87
Earnings to be divided among shareholders		$ 1,428.13

MUNICIPAL PLANT.

Owned by citizens and taxpayers (who are virtually shareholders), commissioners (directors) elected without pay by the citizens and taxpayers from their own number—

Capital invested (bonds)		$22,500.00
[1] Cost to citizens if lights were furnished by contract at $70 per light per year for 100 arc lamps		7,000.00
Expenses per year.—		
New construction	$143.22	
Repairs	246.11	
Tools and equipment	13.42	
Running expenses	1,723.30	
Salaries	2,400.00	
[3] Taxes	192.00	
[3] Water rent	75.00	
[2] Depreciation on $15,576.38 at 5 per cent	778.82	
Interest on bonds, $22,500.00 at 4 per cent	900.00	
Total expenses		$ 6,471.87
Amount saved to taxpayers in reduced taxes		$ 528.13

It should be added that the report, which has been accepted by the committee, is the result of extended investigations conducted by A. E. Winchester, consulting engineer, and an electric light commissioner of the city. He was selected for the work from their number by the following special investigating committee on commercial electric lighting:—Stephen S. Hatch, Frank N. Ferris, Oliver E. Weed, Councilmen; John H. Light, City Attorney; Joseph A. Volk, Leslie Smith, Albert E. Winchester, Electric Light Commissioners. This committee was appointed by Mortimer M. Lee, and the Common Council in response to a strong petition from the citizens of South Norwalk, Conn., urging that commercial electric lights be supplied from the city's existing municipal electric street lighting plant, which has been operating under a high degree of success and economy for several years.

---

[1] It should be noted that $70 per year is a very low rate for lamps of 1,200 c. p. under any schedule, but it is used out of courtesy to the private plant.

[2] Depreciation (an item as often forgotten by private as well as municipal plants), represents property subject to deterioration.

[3] Taxes and water rent added to expenses of municipal plants to make comparison fair to private plant.

WHY UTICA, N. Y., PREFERRED BUYING ITS LIGHTS.

Below are given the figures cited in an official report to the city council of Utica, made in 1896, on the subject of municipal lighting. After a most exhaustive investigation the committee of the council recommended that instead of installing a municipal lighting plant, a five-year contract be made at 33 cents per night. The comparative cost between municipal plants and private companies follows:

Cost of lights where plant is owned by municipality:—

CITIES—	Cost per hour.	Candle power per hr. fur. for 1 cent.
Alameda, Cal.	.1458	137
Aurora, Ill.	.0447	447
Bay City, Mich.	.0376	531
Bloomington, Ill.	.0519	385
Crawfordsville, Ind.	.0671	298

A KANSAS COUNTY BONDED INTO INSOLVENCY.

The Board of County Commissioners of Lane County, Kansas, have formally declared the county insolvent and issued instructions to the County Treasurer to refrain from further payment of interest on the county's bonded indebtedness. The funded debt of the county is $125,000. The bonds are held by about forty different corporations and individuals in New York and New England and have been quoted at almost par. Edward Helmie, chairman of the County Board, states that this action was taken simply because the county could not raise money enough by taxation to meet its obligations. He asserts that the settlers of Lane County are not repudiators, and pay their taxes promptly, but that such is not the case with non-resident land-owners. He cites as an example the Jarvis-Conklin Mortgage Company, which owns ninety quarter-sections of land in the county, and has not paid a cent of taxes for nearly three years. About $109,000 of the county's indebtedness is represented by bonds issued to aid in the construction of the Great Bend branch of the Atchison, Topeka and Santa Fé Road.

DISCUSSION OF MUNICIPAL LIGHTING PLANTS IN MASSACHUSETTS.

We append a report as to what some Massachusetts Mayors are thinking about the subject of municipal lighting plants:

Mayor Farnham, of Malden, thinks they can save from 30 to 50 per cent. by purchasing the electric light plant and furnishing its own light. He says the present contract expires next March, and that the city has been paying $25,000 per year for 93 arc lamps and 780 incandescent lights, which burn on an average 25 nights a month. He recommends that the next contract be made for not more than a year, as the city may decide to do its own lighting.

Mayor Fish, of Taunton, favors the appointment of himself and the president of the Common Council as a committee to act in conjunction with the Street Lighting Committee in the establishment of the municipal lighting plant.

Mayor Turner, of Salem, says: "The cost of lighting our streets is more than $40,000 a year. The city would obtain better service at a much cheaper rate if it had a plant of its own. I recommend that Salem apply for the necessary legislation to enable it to construct its own plant."

Mayor Greene, of Fall River, does not deem it advisable at this time for the city to maintain an electric plant of its own.

Mayor Ransdell, of Lynn, in alluding to the matter of street lighting, says that it seems to be a fact that provisions for supplying light can be made on public account at a cost very much less than what is charged by private concerns.

Mayor Hawkins, of Pittsfield, recommends the placing of electric wires underground.

Mayor Brickett, of Haverhill, says: "Our street railways own valuable franchises, granted on terms which sometimes seem too favorable, but no factor is more essential to the growth of the city than a successful street railway service. Such enterprises must be encouraged upon a reciprocal basis. In return, we should expect good service and fair treatment as to the repair and maintenance of streets through which the lines pass. The expediency of a municipal lighting plant should be considered."

Mayor C. P. Bond, of Waltham, advocates a plan whereby the city will receive pay for franchises granted to electric car companies and other privileges in the public streets. He advises an imitation of the systems, whereby such corporations pay the annual rental for the use of the streets. He advises an imitation of the systems whereby such corporations pay an annual rental for the use of the streets.

Mayor Jenkins, of Lawrence, devotes the greater part of his address to the question of municipal franchises, in respect of which he says: "With the exception of the N. E. Telephone and Telegraph Company making a discount of 25 per cent. on telephones used by the city, Lawrence receives nothing in return for many valuable privileges that have been given away. The electric road, gas, telephone and electric light companies all have important franchises, and the city ought certainly to receive some reasonable return for such privileges."

The city of Boston, under the leadership of Mayor Quincy, is establishing isolated electric lighting plants in its various public institutions, and is now installing large plants in the City Hospital and in the Deer Island prisons.

At Brockton recently the Common Council refused to agree with the Aldermanic Board to bind the city by a new contract for five years for the same arc lights as at present, with an additional charge for incandescents. The present contract has about two years to run, and it looks as if Brockton may have its own plant before the end of that time.

LIGHTING COMMISSIONS.—Both in New York State and in Michigan it is proposed to establish commissions having direct control over corporations engaged in lighting.

MAYOR GREEN, OF BINGHAMTON, N. Y. OPPOSES MUNICIPAL PLANTS.

IN his annual message to the city this year, Mayor Green, of Binghamton, N. Y., addresses himself to the municipal plant question and says: "The business of electric lighting is one of recent origin, and many central stations neglect to include the contingent expenses, which expenses from the very nature of the business are in many cases larger than were expected by the most careful estimates. Then, too, from the nature of the business, the life of the apparatus is short, hence the natural desire on the part of private corporations for a long contract, in order that the cost of renewing and maintaining the apparatus may be warranted by a known period for as long a time as possible.

"We have not undertaken to compile recent, statistics on electric lighting outside of New York State, but have submitted enough to convince intelligent beings that the hypocritical howl that your honorable body did the city a grievous wrong by entering into the recent contract is simply ridiculous, since the statistics submitted prove that this city receives 133 more candles per hour for one cent than the average price paid by the several New York State cities mentioned herein.

"Had you favored establishing a municipal plant, it would at first have required State legislation; then it is safe to assume more than one year would have been required to locate and establish the plant. Your action in accepting the three years' proposition was, in my judgment, in the interest of economy. The city is now provided with lights at a fair price, and for a period which will enable thorough investigation to be pursued regarding the advisability of owning and operating a municipal electric lighting plant.

"My experience has demonstrated that it is almost impossible to secure thoroughly reliable data from cities owning municipal plants. So much of uncertainty concerning actual and contingent expenses maintains that it is difficult to restore order from the general chaos. Your honorable body should carefully investigate and keep in touch with the changes, and the moment tangible facts prove that it is sufficiently cheaper for the city to own its lighting plant instead of contracting for its lights, then it becomes your duty, as well as mine, to undertake the preliminary work of establishing a municipal plant, in which case we should first determine if some amicable and favorable plan could be adopted to purchase the plant from the private corporation now located here. The logic of the situation does not demand the killing off of vested interests and the ruination of a private enterprise if such an unhappy result can be avoided with full justice to the city and its manifold interests, any more than it follows that the city should submit to any extortionate demands from said private corporation."

This was accompanied by figures worked out as far as possible, showing that Binghamton is getting its light cheaper than a city plant could furnish it.

A PROPOSED GOVERNMENT INVESTIGATION OF MUNICIPAL PLANTS.

The proposed Federal state investigation into the municipal ownership of big enterprises, is now under way in several of the States. Its chief aim is to ascertain the extent to which municipal ownership has been carried in this country and to this end information is to be collected from all electric light or water works under such control. This amounts to the making of a census of all this class of municipal enterprises.

The secondary object is to collect data bringing the cost to the consumer of water, gas or electric light under municipal management, into comparison with the cost of a like product under private control. An attempt also will be made to find the cost of the different products under the two methods of management.

The inquiry will be carried on by the different State bureaus of labor and the federal department of labor. There are thirty-two State officials. Some, however, are unable to join in the inquiry and from such States the department will collect the facts. The results will be brought together, compiled and analyzed by the department of labor, while each State participating in the canvass, will publish the data belonging to it. In this way thorough co-operation has been secured and the work will be accomplished with the least possible delay.

A LIGHT COMMISSION PROPOSED IN PENNSYLVANIA.

A bill before the Pennsylvania State Senate proposes to create a Board of Gas, Electric and Light and Water Commissioners. The Board is to consist of three members, appointed by the Governor for three years, one of them to belong to the minority party. No person shall be commissioner or hold any position under the commission who is connected in any way with any gas, electric light or water company, or owns stocks or bonds therein.

The board shall have general supervision of all corporations engaged directly or indirectly in the manufacture and sale of gas, electricity for lighting and the furnishing of water for domestic or fire purposes.

It shall have the same right to subpœna witnesses as a Court of Record, and the board may, upon the request of the local authorities, investigate the quantity, quality and price of gas, electric light or water, or may do the same on complaint in writing, signed by 20 customers in a city of less than 10,000 inhabitants or 50 customers in all other cities.

Upon the commissioners' own volition they may investigate the construction of all such plants, particularly those of water companies. After a hearing the board may order any reduction in the price of gas, water or electric light or any improvement in the quantity, quality or service thereof.

The annual salary of the chairman of the board shall be $5,000 and each of the other members $4,500. The secretary, who is to be appointed by the board, would get $3,600. The total annual expenses shall be borne by the corporations involved, proportioned by the Auditor General in the ratio of their net incomes.

THE DISMAL MUNICIPAL PLANT EXPERIENCES OF HAMILTON, O.

A TYPICAL instance of the troubles which fall frequently on municipal lighting plants is furnished by Hamilton, Ohio, where an order was given recently to discontinue the electric light plant because the city was out of funds for it and could only go ahead by borrowing a further large sum of money. The city owns waterworks started in July, 1884, which cost $315,000; gas works started in August, 1889, which cost $160,000, and an electric light plant started in October, 1895, which cost $100,000. This amount of $575,000 was raised by selling city bonds. The situation in Hamilton is an interesting and complex one, and we cannot do better than let the city clerk, Mr. M. O. Barns tell the story. He says:

"The threat of the gas trustees to shut down the electric light plant the first of the year demands some attention from the citizens of Hamilton. It is not assumed that the action of the gas trustees is caused by pique on their part, as much as to the fact they are out of funds.

"Hamilton of all the cities in the United States has been most afflicted with the 'municipal ownership craze' and now having its fill on theory is reaping the result of 'biting off more than it can chaw,' and we must bear and grin as best we can under adverse circumstances.

"But on the condition that now confronts us we ought to try and inject a little common sense into the 'municipal cranium' and try and evolve some scheme whereby we can 'kite' along for the present and perhaps realize some of the fond expectations that were held out in the past. We are deluded in the belief that we have cheap water, gas and electric light, but when we add to these luxuries the fact that we have so raised the rate of municipal taxation until it has become burdensome and then compare with other cities of our size we are not as well off as we think we are.

"We are taxed to pay the interest on the water works bonds as well as to provide for their redemption, but the city is furnishing free water for municipal uses which is a great point in its favor, while on the other hand we are taxed to pay the interest of the gas works and the electric light plant, as well as to provide for the redemption of bonds but we are also taxed for the purpose of 'lighting the corporation' which is nothing more than double taxation. This is a curious situation, but is nevertheless true.

"While the water works tax levy is up to the limit it fails to pay the interest and bonds falling due and the same may be said of the gas and electric light levy, and they also barely pay the interest charges, with no bonds yet falling due. When they do commence to fall due, how they are going to be paid is a serious question. We should realize that the annual interest charge for water works is $15,500; gas works, $7,500, and electric light, $5,000, making a total of $28,000 with $10,000 of water works bonds falling due each year, making a total charge of $38,000 which must be paid annually, and as no assistance is rendered by either of said plants in helping to pay said charges it looks like the city is carrying a heavy burden.

"This leads to a point where some attention should be paid to doing something that would in a measure help the city out of this dilemma.

"If these plants were owned by a private corporation they would certainly be made to pay at least the fixed interest and bonded indebtedness charges or else go into liquidation.

"The city ought to be able to make them do the same as private individuals could do, and backed by the loyalty and patronage of its citizens, they at least ought to be able to pay, say, the interest charges, amounting to $28,000 a year, and in doing this taxes could be reduced about $3 per thousand, and thus give the city a chance to make other improvements that have been neglected for want of funds. The city has reached the condition that comes to every individual who reaches out beyond his means. Maturity comes and protest has been avoided during the past year by using heroic remedies. Refunding bonds as they fall due may be in the opinion of many good financiering but that does not pay the debt or discharge the interest which creeps along just the same as the bonds fall due and which must be paid. Hamilton is being devoured whole by its interest charges. During the coming year the interest owing by the city will amount to the sum of $43,035, bonds falling due $48,000, or a total of $91,125, or nearly 90 per cent. of the entire revenue of the city will be necessary for meeting charges.

"If little higher water, gas and electric light charges could lighten the rate of taxation it should be tried, as the time has come for heroic measures. We have had theory long enough, and we must meet the condition.

"This brings us down to the position assumed by the gas trustees in regard to the money they have on hand and which they refuse to use for the electric light plant. They ask for $15,000 and say if the people vote for the issue they will buy the bonds with the money they have on hand. In other words they want to rob Peter to pay Paul. They want to compel the city to pay interest on its own money; they want to increase the bonded indebtedness of the city as well as the interest account.

"Their position is not well taken, however sincere they may try to appear to the public. If they have money to loan to the city they should do so and not ask the city to pay interest for it as the city has never asked them to pay interest on the $15,000 loaned them to start their plant, or even pay the bonds as they fell due. If they have this surplus they should be compelled to pay it back into the fund of the city and then the city will give it to them again to run the electric plant.

"They claim they must pay the bonds as they fall due, but if they don't or can't, the city must. The water works did it once or twice and then failed and the city stepped in and took up the 'thread' where it broke off.

"A special election advertising it and selling and printing the bonds will cost close onto $800, and it is very doubtful if the citizens will vote any more bonds and this money—nearly a year's interest—would be thrown away.

"The gas trustees should use a little common sense and come down from their high horse and use a little reason and this matter can be amicably adjusted. The gas trustees by law are charged with lighting the corporation and they must do it. The electric light plant was built for the same purpose as the gas works and the consolidation of the two plants makes them one in the eyes of the law, and the trustees can't draw the line and make a fine hair distinction."

MUNICIPAL PLANT CARELESSNESS COSTS JACKSONVILLE, FLA., $1,500 IN AN ACCIDENT SUIT.

In an action brought against the city of Jacksonville, Fla., for accident damages, the local United States Court has just awarded a decision for $1,500, which amount is added to the city indebtedness. The complainant was sent late on the night of March 13, 1896, to deposit letters in a United States letter box. As he came to the place where the box had been for a long time located, he stepped and fell into an excavation, which the city, through its agents or employés, had dug at the place, and which had been negligently suffered and permitted to remain open and uncovered. The excavation had been made within the curb line of the street, and was about three feet in diameter, and five feet deep. The claim was also made that the city electric lights in the vicinity were not burning as usual that night, and that no notice was posted to warn pedestrians of any danger in the excavation. The result of the fall in the dark on the plaintiff was to wrench and sprain his right ankle and severely to sprain the lumbar muscles of his back, from which injuries he suffered seriously and was hindered from the discharge of his customary duties. In addition, he claimed to have expended considerable sums for physicians' services and medicines.

The jury found the case to be proven against the city and brought in a verdict for $1,487.

OPINIONS FROM LEADING MEN AND COMPANIES AS TO MUNICIPAL PLANTS.

We have received from leading companies and from prominent men in the electrical field interesting expressions of opinion on the subject of the municipal ownership of electric light plants. The attitude thus shown toward the subject is of considerable importance.

Mr. S. D. Greene, general manager of the Lighting Department of the General Electric Company, writes:

In reply to your recent inquiry I beg to state that the position of this company with respect to municipal ownership of electric lighting plants has been consistent since the organization of the company. We have always opposed such ownership, not because we believe that a city can be better and more economically served by a private company (under proper regulations and restrictions), but also because we see no more reason why municipal ownership should apply to electricity than to the supply of gas, fuel or any other commodity necessary or useful to the citizens of such city. Private enterprise and capital are always more keenly alive than municipalities to improvements in machinery or methods of manufacture of such a commodity as electricity, and existing competition affords the best possible stimulus to the introduction of such improved methods in order that the cost of production and price to consumer may be reduced.

It is, of course, obvious that a duplication of investments in illuminating plants is undesirable from every point of view, and the establishment of commissions, or the adoption of any other means to restrict such duplication of properties, is to be commended. The inevitable result of such duplication must be to destroy absolutely a considerable portion of such investments, or to place upon the community the burden of high charges required to pay interest on such extraordinary investments. Because of this, we firmly believe that franchise privileges should be very carefully guarded, and that municipal ownership should never be encouraged upon any other basis than that of acquiring the properties already established by municipal encouragement and authority.

We strongly favor a commission, such as the Board of Gas Commissioners of Massachusetts, which has established strict rules with reference to the conduct of local gas and electric light companies, such as increases in the issues of stock or bonds, etc., but which also protects these companies, where they are honestly and properly administered, by refusing to grant franchises to new competing companies which will threaten or destroy the value of the securities of the companies already doing business. The result is that the securities of both the gas and electric light companies of Massachusetts are steadily appreciating in value, the citizens of the cities and towns have good service at reasonable rates, and investors buy the securities of these companies because they feel that the companies are assured of a reasonable future business. At the same time, if the citizens of any particular locality desire to acquire a municipal plant they can do so under the State laws, provided they first acquire existing local plant or plants at a fair valuation.

We do not believe in attempting to hamper the citizens of any city in the exercise of their undoubted right to have their electric lighting furnished as they choose, but we do believe that no city should be allowed to install its own municipal plant where there already exists a private plant or plants operating under franchises, and which are giving good service at reasonable rates, without acquiring such plants at a fair valuation. The stockholders of such a local company, who have invested their money in good faith, on the assumption that the city will protect them under the franchise which it has granted, are certainly entitled to reasonable consideration.

Prof. S. H. Short, of the Walker Manufacturing Company, Cleveland, Ohio, says: I have noticed the agitation in the various papers with reference to the municipal ownership of electric light plants, along with the agitation for the municipal ownership of electric railways, and everything that is owned by private corporations which secure franchises from municipalities. I do not believe that as good service can be secured, or that the service would be as economical, if the electric light plants were owned by the cities, as when owned by corporations.

I, therefore, do not believe in the municipal ownership of electric plants, and would not recommend that this subject be considered favorably. The tendency to change officials and employés with every change in the political aspect of the Council or Board of Control, would probably bring a change in the management of the electric plant, which would very much decrease its efficiency.

Prof. J. P. Barrett, the superintendent of city telegraphs of the city of Chicago, writes us: "In response to your inquiry of the 29th ult., regarding my views on municipal and corporate lighting, I would state that I thoroughly believe in municipal ownership of street lighting. It is also my opinion that the city should have the right of furnishing current to its citizens as a precautionary measure against extortionate rates charged by private corporations. Where, however, fair rates are charged, I think it proper to permit private corporations to retain such privileges."

ST. JOSEPH, MO., SELLING ITS PLANT.

After an unsatisfactory experience with its municipal plant, St. Joseph, Mo., is now selling out. The St. Joseph Light, Heat and Power Company has submitted a proposition to the council to purchase the city's lighting plant and to light the city. The proposition, is to pay the sum of $60,000 for the plant, in twenty annual installments of $3,000 each, and to furnish electric street lighting at the rate of $85 per lamp per year for 400 2,000 candle-power lamps, and at $75 per lamp for all over that number. The proposition was referred to a committee of eight aldermen, the mayor, counselor, engineer and comptroller, and the Commercial club is requested to delegate eight of its members to act with this committee. The plant cost $90,000.

DETROIT MUNICIPAL PLANT COMMISSIONERS OPPOSE PRIVATE LIGHTING.

So far as the Detroit lighting commissioners are concerned, the proposition made by Mayor Pingree in his annual message to the council that the city go into the private lighting business, does not meet with substantial encouragement. In fact, some of the commissioners express themselves as unalterably opposed to such an undertaking. The reasons given are numerous and cover a good deal of ground. The most outspoken member of the commission is J. L. Hudson. His position is that the city has no moral right to enter into competition with a legitimate and established private enterprise, as he considers the business of furnishing light to private consumers. Speaking about the subject, he said:

"There is more than $1,500,000 invested in lighting plants in this city by private individuals and I think the city has no more right to announce to the public that it will furnish light to their customers at what has been stated as the present cost than it would have to go into any other branch of the mercantile business on the same basis. This capital has been invited to the city, and I should not be in favor of throwing cold water in its face. The city should furnish its own lights, as many large private consumers do, but I think it should go no further. So far as private economy is concerned, I think it would be wise if every consumer who uses over 100 lights would put in his own plant and furnish his own light."

Commissioner R. H. Fyfe was opposed to the recommendation on entirely different grounds, although he stated that the rights of the present lighting companies should be considered when the matter comes up for final adjustment. His position was that the city could not extend its present system without largely increasing the expense of the product and that, considered solely as a business venture, the city would make an unwise move in going into private lighting. He said:

"If the city should extend its lines over a greater district, and, after going to all the necessary expense, be obliged to depend on making collections from small consumers to meet its expenses, the cost of furnishing light would be so greatly increased that the consumers would gain but little. The time may come when the city may profitably go into commercial lighting, but I am firmly convinced that the time is not now. We are at present furnishing light only where our returns are sure and the current sent out is steady. To connect the system with a countless number of small consumers, who would use one light part of the time and a dozen another part, is an undertaking the extent of which cannot be accurately estimated. It would necessitate laying an immense amount of wire underground, entailing a correspondingly large expense. Of course, we could do nothing in the matter without State legislation, and I hope none will be enacted at present."

Commissioner Farrand said: "I don't think we should do anything in the matter at present, although something of the kind may be advisable later. There are so many points that necessarily enter into an intelligent consideration of the case that a man cannot express a valuable opinion off-hand. At present we are extending the system to furnish light for some of the more remote city engine houses and it may be that in connection with this work, commercial lighting may at some future time be practicable and advisable. At present, however, I do not think we should rush into the venture."

A STRANGE MUNICIPAL PLANT EXPERIENCE OF HUDSON, MASS.

It is a strange experience which Hudson, Mass., has had with the question of municipal lighting. It has just been compelled to purchase for over $15,000 the plant of the Hudson Electric Light Company, and go into business on its own account and against its will. This comes about as the immediate result of a decision of the Supreme Court after litigation extending over three or four years.

Almost immediately after the Massachusetts municipal lighting law was passed in 1891, Hudson took steps to manage the business. Under the law, a town which votes to do its own lighting must buy the plant of the existing private corporation when there is one, at a valuation to be fixed by commissioners appointed by the Supreme Court. But the law was so framed that unless a town is very very careful about respecting other people's rights it is likely to find itself with an elephant on its hands in the form of a plant which it will not pay to operate.

If the town petitions for a schedule of the plant with the price at which it can be bought before formally deciding that it will go into the business, the company is obliged to furnish the desired information. Then after investigation as to the wisdom of embarking upon the enterprise, the town may vote to do as it sees fit, to buy the plant or not to do so. If it votes to buy the company has no option, but is obliged to sell and go out of business as a private corporation.

But if the town once votes to make its own light, thereby committing itself to the purchase of the existing plant, it appears to be settled that it cannot reverse its decision, and the corporation in turn can then compel the town to purchase at a valuation determined by the courts.

This has been Hudson's experience. Possible without fully comprehending the binding effect of such action, it voted at two town meetings in 1891, on July 1 and again on September 2, in favor of going into the municipal lighting business. Then, after investigation, doubts were expressed as to whether it would pay to purchase the plant of the Hudson Electric Light Company, and so on November 11 a town meeting voted not to embark on the project.

A committee, however, was appointed which reported to the town meeting March 8, 1892, that "in case the town does not desire to operate its own plant, it pass a vote that it will take no action toward the establishment of a plant before May 1, 1897; provided the owners of the existing plant will, within 60 days of the passage of such vote, file in the town clerk's office a waiver and renunciation of all rights, if any, acquired by them by reason of the passage of the town two votes."

A motion to reject this report and to buy the plant was defeated in town meeting by a vote of 79 to 73 and the report was then adopted and approved 80 to 72. But the company, which, by the way, is a Maine corporation, made no such waiver as the town desired it to do. On the contrary it immediately began proceedings in court to compel the town to buy its plant. The town voted to resist these proceedings and engaged counsel.

The court appointed commissioners to set a price upon the plant, and their decision was that the town must pay the electric light company something over $15,000 and take the plant. The valuation set by the company upon its property was about $18,000.

LYNDONVILLE, VT,. PAYING HIGH FOR ITS WHISTLE.

At the Lyndonville, Vt., village meeting on January 28 a resolution was adopted issuing $49,000 in electric light bonds payable in 1913 and 1927. As the bonds sold at 90, this left a deficit of about $5,000, and as this money is needed at once the trustees were authorized to borrow this amount and give a note for the same.

LANSING, MICH., ENGAGED IN "WHOLESALE LARCENY."

Mayor R. C. Ostrander, of Lansing, Mich., has written a sharp article in the Lansing "Republican" on the subject of the municipal electric lighting plant, which he says has now cost all told $106,000 and is far from being worth any such amount. According to him the situation is rather blue. He points out that the city is not selling to the private consumer the quality or value of light that it charges him for, and he says emphatically:

"In thus doing business, the city is really engaged in wholesale larceny. You see, too, that it is impossible to tell what it would have cost the city to furnish the light which it fairly undertook to give the consumer."

Mr. Ostrander goes on to discuss the situation and sums up tersely as follows: "I have said that private lighting should only be undertaken by the city for gain. I did not mean by this that necessarily the account for the year should show a large amount of receipts over expenditures. The plant is operated for gain quite as much when it furnishes its customers good lights at low prices, the consumer being given the benefit of increased efficiency and low cost of operation.

"If the question was now for the first time presented whether the city should embark in the business of furnishing commercial lights, I should most assuredly say that it should not. But we are confronted by a condition. We own the plant, poles and wires. We must either maintain the business or sell it. We cannot hope to sell it for anything like its cost. It seems advisable, therefore, to continue to sell lights if we can do so without loss. I use the word 'loss' in the sense of actual loss. That is to say, the plant ought not only to be operated without loss, but the receipts from the sale of commercial lighting should be equal to the cost of operation and all charges for diminution in value of the plant. If the city cannot furnish a good light to its customers at as low a price as a private corporation could furnish the same light, it ought to go out of the business and charge the loss up to experiment fund.

"Reconstruction of the system, so far as it relates to commercial lighting, has begun, and evidently it must continue at considerable cost."

MASSACHUSETTS TOWNS NOW WANT TO BUY STREET CAR LINES.

There was introduced in the Massachusetts House on February 6 a petition which will be regarded as a most important one, from the names upon the paper. It asks the Legislature to give cities and towns through which street railways pass the right to take these properties, construct, own and operate street railways, on any part thereof. The petition asks that the management of the roads taken may be vested in such persons as the railroad commission or governor and council may select, or in a special board to be created for the purpose.

The petition is signed by Robert Treat Paine, Thomas Wentworth Higginson, Edward F. Hale, Josiah P. Quincy, Edwin D. Mead, Frank Parsons, W. L. Rutan, K. K. Foster, Harry Lloyd, F. C. Coffin, Mr. Cox, of Melrose, and some others.

It is also said that later petitions will bear the names of Harvey N. Shepard, Levi N. Gould and other prominent men.

MARQUETTE, MICH., PLANT WANTS $35,000 MORE FOR A WEAK DAM.

The unexpected nature of the heavy charges that may come upon a city plant, as well as the part they may play in local politics is indicated by the subjoined from the "Marquette Journal" of January 30.

Electric Light and Power Commission No. 3 has depleted its treasury in making cribwork at the dam with the expectation of keeping the structure from washing out in the spring. It has been working several months on plans for the permanent improvement, and is getting its work in a shape where it will soon be able to report to the council and make a recommendation.

It intends to make this report while the present councilmen are in office and it is sure of its friends rather than to wait till after election, and take a chance on finding more friends among the newly seated aldermen. Perhaps a more potent motive than this is that the board will have its plans ready and will prefer to make a recommendation as soon as it can, so if they meet approval, money will be voted and work can be begun early in the spring.

The board now in office expects to do the work more economically than its predecessor figured it could be done for. Part of this saving comes in the use of the Jacobs dam, which the No. 2 board planned either to tear down or abandon, and by the use of material which has already been purchased, and is now lying on the ground or is in various parts of the work which will have to be rebuilt. The board expects to effect a further saving on the purchase of material buying from first hands.

It is understood that the board wants $35,000, and as its own fund is depleted, and there is no other fund out of which this could come, the council must needs be asked to submit a bond proposition to the city at the coming election. This may furnish an issue for some of the half dozen mayor candidates to stand upon.

HOW POLITICS GOT INTO THE MIDDLEBORO, MASS., MUNICIPAL PLANT.

The committee on manufacturers of the Massachusetts legisture gave a hearing recently on a petition of persons in Middleboro who are dissatisfied with the way the electric light plant in that town is run. It is a municipal plant, and the removal of a former manager, Mr. Mayne, seems to have created a good deal of the trouble. When Mr. Mayne was removed, J. B. Ryder was chosen manager. Mr. Mayne told the committee that Mr. Ryder had never had experience in running the plant, and knew nothing about electricity.

An ex-member of the board of commissioners, Mr. Wood, said the plant was run more in the interest of politics than for the interests of the town. He said two members of the board had elected Mr. Ryder manager, he being a member of the board and voting for himself. He said he was opposed to a member of the board being elected manager anyway.

He favored the passage of the bill offered by Mr. Pratt, of Middleboro, to provide that members of municipal light boards shall not hold office of manager by appointment of such boards. He was opposed to the election of any man who had no qualification for the position.

Mr. Ryder defended himself and said there had been no complaint made as to his conduct of the office. He knew of no abuses. Henry Wilkins, manager of the Marblehead electric light plant, objected to the bill and so did J. B. Litchman, chairman of the Marblehead light board.

Eugene Le Baron of Middleboro favored the bill and said no man should be placed in the position of having to pass upon his own acts as manager, as he must, if a member of the board.

CITY PRIVATE LIGHTING AT TACOMA, WASH.

An attempt was made some time ago, by Tacoma to nearly double the present rates for electric lights, but when the ordinance was brought before the light committee of the council it refused to recommend it. Then other plans were laid, but none of them seemed to give satisfaction, for the reason that all of the proposed rates would permit the opposition company to compete with the city.

Many claim that if the city raises its rates more than 10 per cent., it will lose 90 per cent of its commercial business, while, if it would only run the plant as a plant ought to be run, it could pay all charges for operating as well as interest on its bonds.

HOW NEW YORK CITY GETS ITS STREET LIGHTS AT BARE COST.

In his interesting annual report for 1896—97 referred to elsewhere in this issue, vice-president R. R. Bowker, of the Edison Electric Illuminating Company of New York City, says, with regard to the city street lighting: The lighting of Fifth avenue on the Edison system had given such general satisfaction that last year, at the request of citizens and of the city authorities, this service was extended to a portion of Madison avenue, from Fifty-ninth street to Seventy-second street, which was not lighted by electricity. This year the insistent requests of the residents of Madison avenue for the extension of that system south to Twenty-third street, have resulted in an arrangement with the city authorities under which Madison avenue, from Twenty-third to Seventy-ninth streets, as well as Fifth avenue from its beginning to the same streets, will be lighted by the Edison-Bowker two-arc system, which will also be extended to some of the wider cross streets. The Commissioner of Public Works, who made during the early winter a visit of inspection abroad, reported on his return that "no street lighting in Paris or London excels the Edison lamps on Fifth and Madison avenues for beauty or illumination." This form of lighting is, however, somewhat more costly than other electric lighting throughout the city and, in co-operation with the city authorities, a system of single lamps for street service will be installed in other streets where there are Edison mains, to the extent of about 200 additional posts. The price made to the city is below the actual average cost of current to the company, but the hours of burning are unusually long, giving employment for the station equipment during hours when there is little demand upon it, and this fact, conjoined with recognition of the fact that the city should enjoy the benefit of the best possible rates from a corporation making use of the public streets, has justified a price very much below that necessarily charged for commercial lighting.

THE FIGURES OF THE BROOKLINE, MASS., INVESTIGATION.

EXTENDED reference was made in The Electrical Engineer of Jan. 20 to the official report submitted to the City of Brookline, Mass., by Mr. Nathan Matthews, Jr. In connection with the present discussion in the columns of this paper, we now give the two tables embodied in the report and the conclusions arrived at after the full discussion of all the data:

TABLE OF ANNUAL COST, BROOKLINE, MASS., REPORT.

Estimated by	Capacity of Plant.	No. of Lights Run.	Labor.	Fuel, Materials, Repairs, etc.	Insurance Against Fire and Accidents	Depreciation Fund.	Interest. Account.	Total.	Total Cost per Lamp.
W. Jackson	500	250	$10,236	$8,305.00	$1,200.00	$11,108.26	$6,609.48	$37,458.74	$149.83
"	500	375	12,836	11,857.50	1,285.00	12,855.39	7,308.36	46,142.25	123.04
"	750	500	15,280	15,710.00	1,650.00	17,796.30	10,006.52	60,442.82	120.88
Stone & Webster..	375	250	10,236	9,308.75	606.60	6,782.26	3,567.34	30,500.95	122.00
"	500	375	12,836	13,364.95	792.22	9,365.39	4,869.88	41,228.44	109.94
"	750	500	15,280	17,717.50	1,044.12	12,639.52	6,639.69	53,320.83	106.65

With regard to a list of certain "economical' plants, Mr. Matthews gives the following:

TABLE SHOWING ALLEGED AND REAL ANNUAL COST PER LAMP OF CERTAIN MUNICIPALITIES.

Town or City.	Number of Lights.	Candle Power.	Alleged annual cost.	Real Annual Cost.
Bangor, Me. (a, b)......	150	2,000	$48.00	$79.00
Lewiston, Me (a, b).....	100	2,000	55.00	65.50
Peabody, Mass.	150	1,200	62.00	100.05
Bay City, Mich..........	181	2,000	58.00	76.25
Goshen, Ind. (b)........	240	2,000	77.00	111.54
Bloomington, Ill. (b)....	240	2,000	51.00	93.64
Chicago, Ill	1,100	2,000	96.00	181.83
Elgin, Ill.	98	2,000	43.00	100.73
Aurora, Ill. (b)..........	200	2,000	70.00	87.57
Fairfield, Iowa (b)......	16	2,000	70.00	117.16
Ypsilanti, Mich. (a).....	88	2,000	36.00	77.84

a. These plants are run by water-power.

b. These plants are operated in connection with other works.

"Of the above municipalities only two—Bangor and Chicago—run their lights all night throughout the year. The rest run on schedules—moonlight and other—amounting to from one-half to three-quarters of the standard all-night schedule time."

In his conclusions Mr. Matthews says:

(1) The probable cost of a first-class plant sufficient to supply street lights to the number of 375 with a reserve capacity of 125 more could be built on the overhead system upon suitable land now owned by the town for about $121,000.

(2) Such a plant could be operated at an annual cost, including interest at 4 per cent. on the total investment and a depreciation fund sufficient to renew the entire plant every ten years, for about $41,000, or about $110 per lamp per annum.

HOUSTON, TEX., PROPOSES TO SELL LIGHT.

Alderman G. C. Street, who has been handling the correspondence for the city council on the subject of the city erecting and owning its own electric light plant, has received several letters and propositions from parties in that line. He is introducing a resolution to issue $100,000 of bonds for the erection of such a plant. He also said that from the best information his researches had brought, the city could build a plant for that sum, and in four years the amount saved from the price now being paid for lights by the city would pay for it. His idea was that the city would furnish not only its own lights, but supply them to patrons, and also supply power, which would increase the value of the plant to the city. He also stated that the council would likely push it through as rapidly as practicable.

MUNICIPAL PLANT POLITICS AT GRAND HAVEN, MICH.

A dispatch from Grand Haven, Mich., of February 10, says: The city has been operating its electric light plant under the control of the board of public works, subject to the approval of the council. The board and council have quarreled over the city electrician, who has resigned. Another was elected. The board accuses the council of desiring to put men in charge of the electric light plant who are related to certain aldermen.

The council accuse the board of trying to create liability without reference to the council, and have instructed the city treasurer to pay no bills not approved by the council.

Meantime the spring elections are anticipated and merry times are promised.

A CITY PLANT AS A "CULPABLE LUXURY."

There has been a good deal of discussion lately as to what constitutes "culpable luxury." The little town of Stockton, Mo., appears to have settled that point, to its own satisfaction at least. It is selling its electric light plant and will return to plain and unpretentious petroleum. The town was going to do wonders with the plant and make money enough to do lots of things, but the fond dream is over. The Kansas City "Star" says that the plant is "a luxury that the present hard times will not stand."

ELECTRIC LIGHTING FOR CARACAS.

The municipality of Caracas, the capital of Venezuela, according to the Monthly Bulletin of the Bureau of American Republics, has recently made a contract for the establishment of an electric lighting plant there. The contract requires the installation of 400 arc lights in the streets, squares and public places of the city, and 500 incandescent lamps for the municipal buildings. In addition to the installation referred to above, the national government has ordered 1,000 incandescent lights for the public edifices, and 100 arc lights to be placed in the Paseo de la Independencia, which is the famous drive of the city.

The motive power to be used will be water, taken from the falls of the Macuto River, which are estimated as being capable of producing 6,000 h. p. The water will be concentrated at a height of 2,600 feet above the turbines, it is said, being the highest utilized waterfall in the world, exceeding the famous Comstock mines of Nevada, which has a vertical fall of 2,100 feet.

LOWELL, MASS.—The Lowell Electric Light Company is running 695 arcs and 14,000 incandescents and is furnishing 818 horse-power of motors to 110 customers.

BUFFALO, N. Y.—The Cataract Power and Conduit Company has asked for a six months' extension of its time for being ready to deliver 10,000 horse-power in the city by June.

OF A HIGH ORDER.—The Electrical Engineer, published in New York, is now 16 years old, and celebrated its anniversary, says the "Western Mining World," by issuing what it termed a Crystal number, of 132 pages. This is no doubt the largest single magazine ever published devoted exclusively to electricity. Its contents are of a high order and very instructive to the layman as well as the electrician. The price of the issue is only 10 cents and any one at all interested in electricity should send for one.

THE ENCLOSED ARC LIGHT.—IV.

BY L. B. MARKS, M. M. E.

EFFICIENCY OF THE ENCLOSED ARC.—On a previous occasion I published some curves showing the relative radiant efficiency of the enclosed arc, one of which curves I will reproduce here for you in contrast to the efficiency curve of an average open arc.

Referring to the diagrams, Figs. 7 and 8, the dotted line curves indicate the relative luminous and total radiation of the lamp at various angles below the horizontal is given in the heavy line curve which therefore represents the radiant efficiency of the arc. In the case of the enclosed arc the measurements are given for a clear glass enclosure; in the case of the open arc the readings are given for the naked arc, no globe having been used. The mean hemispherical efficiency of the enclosed arc was found to be 8.4 per cent.; that of the open arc for the same current was 11.7 per cent. It will be noted that the efficiency curve of the enclosed arc differs materially from that of the open arc, the distribution of light in the former being more uniform than that of the latter. In the enclosed arc the change in efficiency from 20 to 60 degrees is inconsiderable, while in the open arc the change is decidedly marked, the curve taking a very sharp turn at about 40 degrees.

The figure which I have given for the efficiency of the naked arc is much higher than that of the average naked arc in service in the United States. From tests which I have made, it is safe to say that as commercially operated the average efficiency of the open lamps falls considerably below 10 per cent. without deducting the loss due to the interposition of a clear or translucent glass globe. When we consider the case of an open in-door lamp with an opal globe such as used extensively in this country and compare the same with that of an enclosed arc lamp as commercially operated, the relative radiant efficiency measurements as given above do not represent the true relative illuminating powers in the two cases. With the open arc for in-door illumination it is necessary to soften the light, in other words, to enlarge the area of the source of illumination. With the common opal globe it is found in practice that from 40 to 60 per cent. or more of the light is necessarily cut out in obtaining the requisite distribution just alluded to. With the enclosed arc, on the other hand, where a thin outer globe is used, this distribution can be obtained with a loss of not more than one-half of that in the case of the open arc, especially when the inner bulb of the enclosed arc is made of a slightly translucent glass.

The conservation of heat in the enclosed arc makes it possible to operate a carbon of given diameter at a relatively higher efficiency than in the open arc. Thus a carbon 11 mm. in diameter operated in the enclosed arc lamp at a current of from 4 to 5 amperes, will give about the same efficiency relatively as a carbon 8 millimetres in diameter operated at the same current in an open lamp. This makes it possible to use a carbon of large diameter more efficiently in the enclosed lamp than in the open lamp. It is found, however, that with with these small currents it is inexpedient for several reasons to use carbons appreciably larger in diameter than the size quoted above.

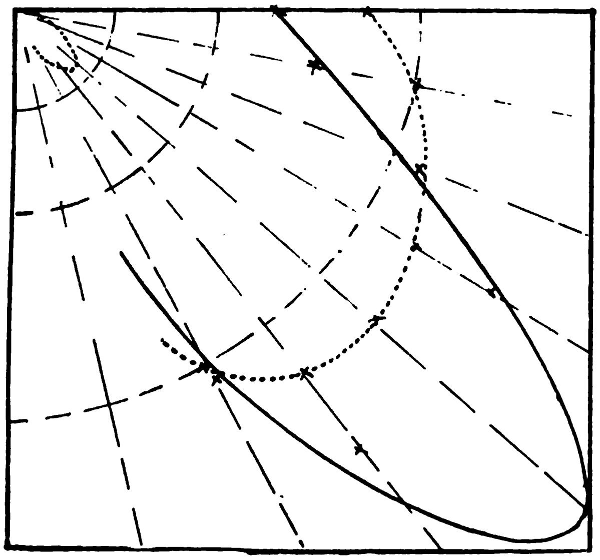

FIG. 7.

First, with the larger carbons the radiation is more rapid and the temperature is decreased; the efficiency being a function of the temperature is therefore also decreased. Secondly, the amount of light cut off by the carbons themselves when the latter are large in diameter becomes considerable; this applies especially to the rays cut off by the flattened tip of the negative carbon.

Thirdly, the coating of the internal surface of the enclosure cuts off light in proportion to the thickness of the deposit. It is well known that all carbons contain a small percentage of impurity consisting chiefly of silica. When the carbons are consumed in the open arc, this silica passes off into the atmosphere. When the carbons are consumed in the enclosed arc, the impurity settles in the form of a thin coating on the internal surface of the enclosure. Although the amount of this deposit is very slight when the carbons are burned only for a short time, the amount of light cut off becomes appreciable when the coating thickens. It has been found in commercial operation in the United States, that after 100 hours' burning the decrease in the illuminating power of the lamp due to formation of this coating is not noticeable by the consumer; after about 150 hours, however, the decrease in illumination becomes objectionable and it is necessary to wipe out the enclosing bulb. Now with a pair of carbons 12.7 mm. (½ inch) in diameter, the life as shown in the test which I have cited is about 200 hours. As a result of this long burning the light efficiency is cut down to an objectionable extent; hence in this case we are using a large carbon at the sacrifice of efficiency from all three standpoints mentioned above.

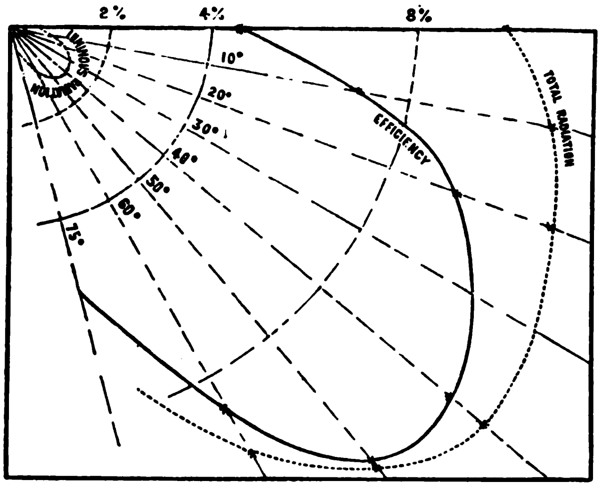

FIG. 8.

LIGHT; ITS DISTRIBUTION AND DIFFUSION AS RELATED TO QUALITY AND EFFICIENCY.—III.

By E. LEAVENWORTH ELLIOTT.

In 1857 M. Degrand took out patents for improvements of Fresnel's invention, and worked out various methods of applying the principle to street lighting. His improvement in the Fresnel lens consisted in pressing the glass in one piece, instead of forming each ring separately—a much cheaper method, but not capable of producing sufficient accuracy for lighthouse purposes. Degrand also appears to be the first to have pointed out the use of glass ribbed with double-reflecting prisms, in place of metal or silvered glass reflectors. His schemes were scientific and ingenious, but were never carried out, possibly on account of their expensiveness at that time. He made no attempt to secure diffusion.

The next step in this line was made by Mr. A. P. Trotter, an English engineer. He took for his problem the uniform illumination of the ground within a circle having a diameter equal to seven times the height of the light-source. To secure this result he used a polygonal lantern, having panes of ribbed glass for the sides, and silvered reflectors for the top. The side panes were ribbed on both sides—the outside horizontal ribs having profiles calculated to distribute the rays by refraction, so as to produce uniform ground illumination, and the interior vertical ribs calculated to produce a certain amount of diffusion by spreading the rays laterally. Here again the expensiveness and complicated construction seem to have prevented its practical use.

A curious idea, theoretically good but practically useless, was brought out by Fredureau in 1891. It is chiefly interesting as being the only recorded attempt to change the quality of the light by means of a globe. His ideas of the results obtainable, however, are strangely erroneous. In describing his invention, he speaks of "the employment of transparent or translucent simple or multiple envelopes—filled with colored or colorless liquid—placed around the source of light. If a source of light be placed within the envelopes filled with a suitable liquid pervious to the rays of light, the light obtained will be diffused, and acquire greater illuminating power, while at the same time becoming more pleasant than if it proceeded from the source of light directly." It is difficult to see how light can be made to "acquire greater illuminating power by being passed through glasses and liquids." He says again: "It should be observed in conclusion that special liquids may be used whereby the light produced will acquire certain peculiar physical and chemical properties, which may prove of great service in many cases; for instance, in the various manipulations connected with photography." In a later specification he seems to have followed this same idea of being able to change the nature of the ethereal vibrations. He proposes to use prismatic rings in such a manner that "The most refrangible rays of the light produced by the voltaic arc (owing to which this light so painfully affects the eyesight) disappear within the said envelope or casing and a whiter light only is allowed to come forth on the outside. The least refrangible rays of incandescent electric lamps diverge generally speaking in the direction of the horizon, so as to allow a whiter light to pass into the cone below. As the result of these effects, the light diffused according to this invention is by far the more pleasant to the eyesight than ordinary electric light, and much more nearly resembles daylight, owing to which fact it will prove particularly suitable for nocturnal photography."

The augmentation of the chemical effect of light by cutting off the "most refrangible," i. e., actinic rays, either by absorption or dispersion, is paradoxical, to say the least. Leaving these claims out of the question, however, his latest globe is of some practical use as a reflector. The outer surface is covered with horizontal prismatic rings, having the upper face of each calculated to keep the rays below the plane of the source. They produce practically no diffusion, and appear luminous in a vertical meridianal band, instead of making the light source appear "equal to the envelope in size," as the inventor claims.

THE KELLY STATIC GROUND DETECTOR.

ONE of the constant vexations of central station operation is the detection and location of grounds. The placing of ground indicators in direct contact with live circuits has the disadvantage of placing a constant strain on the insulation and at the same time entailing a constant waste of current passing through the instrument. To obviate both these difficulties, Mr. John F. Kelly, of the Stanley Electric Mfg. Co., of Pittsfield, Mass., has designed a very simple and unique static ground detector which has proved highly efficient in practice.

This ground detector, shown in perspective in Fig. 1, is essentially a differential static voltmeter made up of four vanes fixed to a base and a movable vane carrying an index or pointer. The movable vane is made of sheet aluminum mounted on a shaft and held centrally, by two jewelled bearings, between the fixed metal vanes. The diagonally opposite fixed vanes are connected in pairs and each pair is statically charged from one pole of some source of electrical supply. The movable vane which is connected to earth is inductively acted upon by each pair of fixed vanes so that the stress produced by each is equal but opposite. The movable vane in consequence takes a position equally between the fixed vanes which position is, theoretically, the same whether the instrument is charged or not, and is the position of "no ground," the pointer pointing to the zero of the scale.

If one pair of fixed vanes and the movable vane are electrically connected, they are charged of like character from one pole of the source, the other fixed vanes being charged of opposite character from the other pole. The action of the similarly charged vanes is to repell the movable vane while the action of the other fixed vanes is to attract it. The two forces acting in the same direction, the movable vane takes the position entirely within the oppositely charged vanes, the pointer pointing to the side of the similarly charged vanes and pointing to the position of "ground" for that side.

The static ground detectors are made in three types: Type A, for use on any two-wire or four-wire circuits of any electromotive forces over 500 volts and under 5,000 volts, and for three-wire three-phase circuits of the same voltages. Type B, is similar to Type A except for electromotive forces of 5,000 volts and higher. Type C, for use only on three-wire two-phase circuits and for electromotive forces over 500 volts and under 3,000 volts.

The general appearance of all instruments is the same, the various types differing only in detail. There is no connection through any of the instruments between the line wires or between either of the wires and earth. It is not necessary to first introduce a temporary ground on the line in order to test for an existing ground, the characteristic of the old forms of ground detectors. This feature is of great importance as it insures greater safety to linemen and lessens the possibility of short circuits in the instrument itself. The instrument consumes no energy and may be left continuously in circuit, indicating grounds as soon as they occur. An instrument for each circuit may, therefore, be used to great advantage.

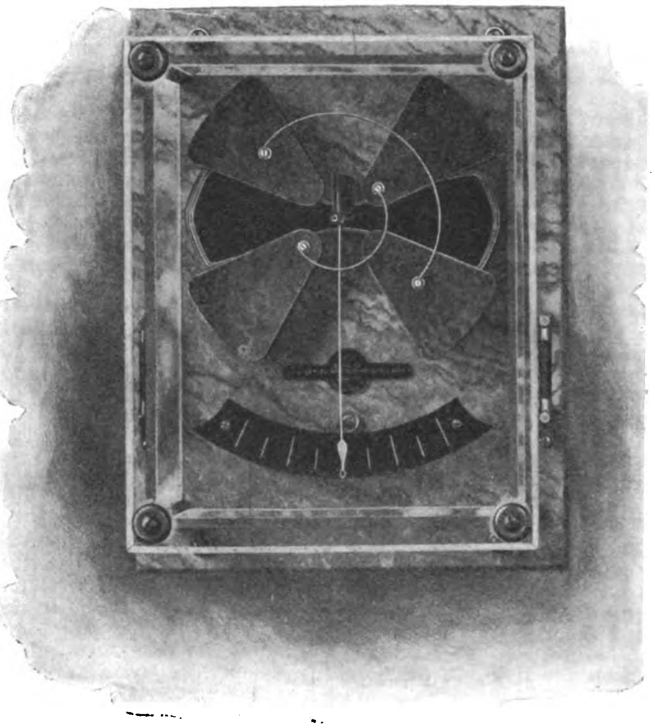

Fig. 1.—The Kelly Static Ground Detector, Stanley Mfg. Co.

In places where severe lightning storms are frequent and where the line is not adequately protected by lightning arresters, it is advisable to disconnect entirely the ground detector or open the "permanent ground wire" during such storms. The first may be done by the commutating switch D, or by the ground plug and cable, A.

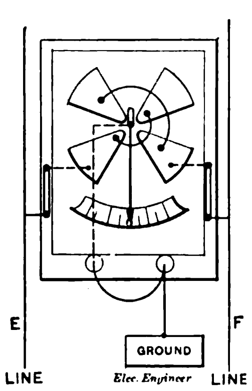

Fig. 2.

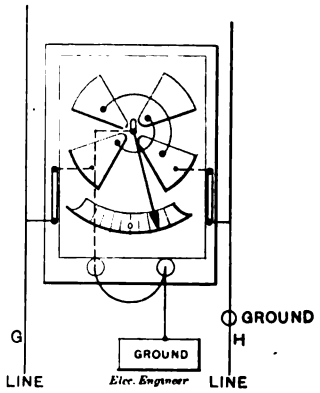

Fig. 3.

Type A is mounted on a separate marble base or directly on the switchboard. It is entirely covered by a case of plate glass, and all parts are perfectly insulated from the operator. The line wires are connected by small terminal plugs through removable fuse blocks, C C, on either front or back of the instruments, to the fixed vanes. By inserting a commutating switch, D, between the line wires and the instrument, it may be transferred safely and quickly from one phase to another or to any one of any number of circuits.

Fig. 2 shows the instrument in circuit with no ground on line, while Fig. 3 shows its position with a ground on the wire at H. Fig. 4 shows the detector in circuit, showing the method of testing when there are grounds on several circuits. Here A shows the ground plug and cable; B the shipping attachment, which holds the pointer in place during transportation, but is taken off when the instrument is set up; C, the fuse; and D, the commutating switch. When testing, the index on the commutating switch indicates the circuit.

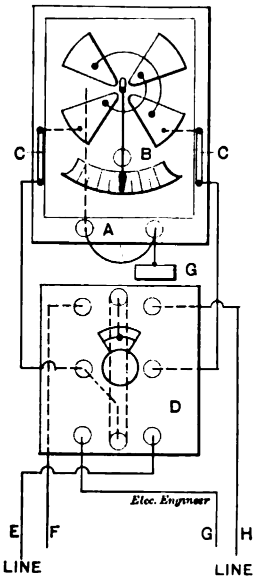

Fig. 4.

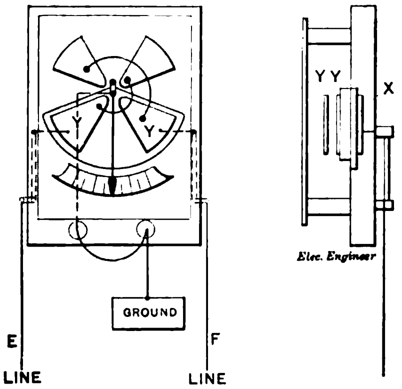

Fig. 5.

Type B, Fig. 5, differs slightly in construction from type A, in that the line wires are connected to a primary set of vanes, X, which are behind the visible fixed vanes, Y Y, and are separated from them by large plaques of hard rubber and mica. The visible fixed vanes are charged inductively from the primary vanes instead of directly from the lines. This type of instrument is mounted on a mahogany base in which are embedded the primary vanes and the mica plaques. This construction secures perfect insulation for very high voltages, while in general appearance and in action the instrument is the same as type A.

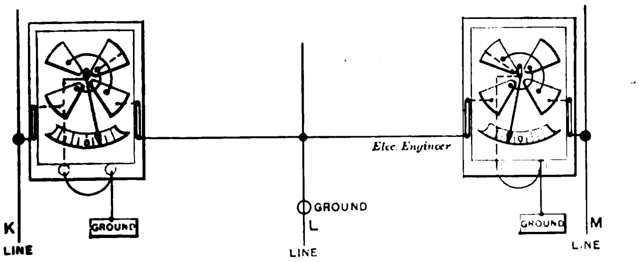

Fig. 6.

Type C, ground detector, Fig. 6, in construction and in appearance is practically the same as type A, differing only in having the vanes connected to the outside wires partially cut away. When the wire, K, is grounded, the pointer is deflected to the left; with a ground on M, the pointer is deflected to the right. With a ground assumed on the middle wire, at L, the pointers are deflected as shown in Fig. 6.

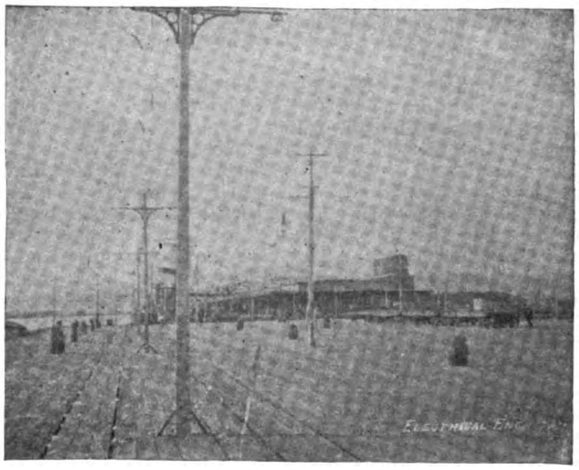
This is claimed to be the only ground detector that will work properly on a three-wire two-phase circuit, others indicating "ground" on the middle wire whether there is one or not on account of the unequal electromotive forces between the wires.

The fuse wire used for all these ground detectors is the well known platinum-silver wire ued in Cardew voltmeters.

ELECTRIC TRANSPORTATION

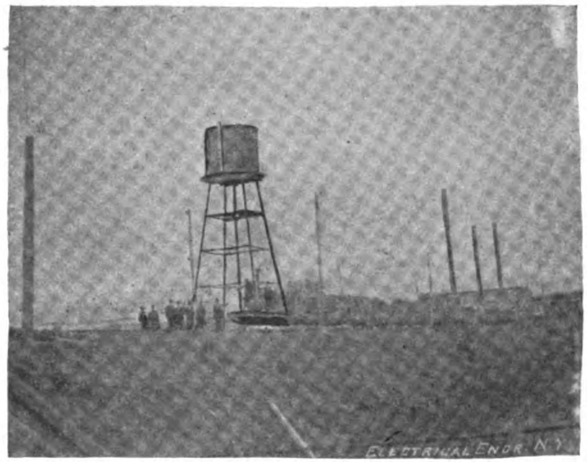
ELECTRIC COTTON HAULER AT PORT CHALMETTE, LA.

THERE has recently gone into operation an interesting electric freight hauling road at Port Chalmette, La., of which we gave several views in the accompanying engravings.



Electric Railway at Port Chalmette, La.

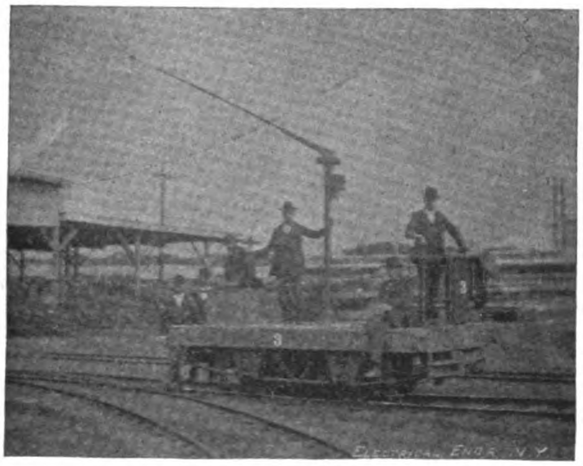
Port Chalmette is the big cotton handling port recently constructed just below New Orleans on the Mississippi. At this point over $3,000,000 has been expended in cotton sheds, warehouses, compresses and wharves. The whole forms a town to itself, lighted by its own electric lighting plant, with arc lights



Electric Railway at Port Chalmette, La.

and 220-volt incandescent lamps. Connecting the sheds, warehouses, compresses and wharves is a system of narrow gauge tracks for handling the cotton.

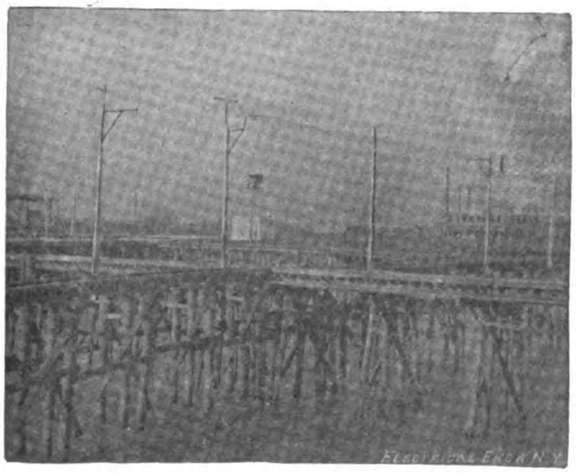
The original promoters adopted compressed air locomotives for the work of hauling the cotton about from point to point. At the beginning of the cotton season last fall, although four air locomotives were in service, they were unable to cope with the handling and moving of the cotton. The managers were skeptical regarding electric traction and the underwriters were afraid that electric motors would increase the fire risk. Something had to be done and done quickly to handle the large consignment of cotton daily received. A temporary trolley line was constructed and an electric truck provided.



Electric Motor for Hauling Cotton, Port Chalmette, La.

An engine and railway generator were hastily secured and inside of ten days the most important part of the hauling work was being successfully handled by the improvised trolley plant. Its working satisfied both the Chalmette managers and the underwriters and the result was a contract was made for four electric haulage locomotives. The apparatus was rapidly installed and by the middle of the cotton season the trolley had supplanted the compressed air locomotives and was taking care of the large and extended haulage system of the entire terminal.

The locomotives are "factory trucks," equipped with two NWP—12 motors, and weighing approximately 15,000 pounds; each is capable of hauling 150 tons on a straight level track.



Electric Railway at Port Chalmette, La.

Current is furnished by a 500-volt railway generator direct coupled to a 300 h. p. Erie City Iron Works engine. The electrical apparatus was furnished by the General Electric Company, through Mr. J. J. Britton, of the New Orleans office.

There are about eight miles of 36-inch gauge track about the cotton sheds, storage warehouses and wharves.

"WEARY."—Mr. C. D. Babcock writes in for The Engineer and says: "I am a trifle weary of my —— covered friend and his chronic lack of news."

TERMS OF THE CHICAGO GENERAL ELECTRIC RAILWAY FRANCHISE.

The conditions of the contract with the General Electric Company are as follows: Compensation: Nothing for first five years; 5 per cent. of gross receipts annually during second five years; 7 per cent. during third period of five years and 10 per cent. during last five years; average of 5½ per cent. per annum for the twenty years.

Fare, 5 cents, for the entire period of twenty years.

Underground system, except on unimproved streets; to abandon overhead within two years on the improvement of any street on which overhead system may have been placed.

Substitution of improved "grooved" rails for the present "girder" rails.

To run no more than two cars to a train.

Transfers on all connecting lines.

TO CONNECT TROLLEY AND ELEVATED LINES IN BROOKLYN.

The contract between the Long Island Electric Railroad and the Kings County Elevated Railroad Company has been confirmed. The companies will build an inclined plane connecting the two roads. The structure will cost about $35,000, and will proceed rapidly. When the incline, which is to be built at the terminus of the elevated railroad at Liberty avenue, is finished, the electric cars will run from the surface up to the level of the elevated structure, and there be attached to the trains and hauled through to the bridge. President Norton of the Long Island Electric Railroad said he thought the running time to the bridge could be reduced, and that the Kings County road would run express trains. The fare between Brooklyn and Jamaica will be 5 cents. To all other points, Mr. Norton says, the fare will be about 50 per cent. of that charged by the steam road. It is said that the line to Far Rockaway will be completed by July 1. The new arrangement adds about thirty miles to the Kings County system.

HEAVY RAILWAY WORK IN KANSAS CITY.

The Metropolitan Street Railway Company, of Kansas City, has awarded the contract for the electrical equipment of the Rosedale line to the Electrical Installation Co., of Chicago. The work of erecting the poles and overhead work will be commenced March 1. The terms of the contract stipulate that the road shall be ready for operation May 1. The construction company will bring its foremen from Chicago, but the laborers will be employed in this city. About 300 men will be given work.

About 350,000 pounds of copper wire will be used in the overhead work. Eight feeder wires will be laid between the Kansas City, Kan., power house and the Rosedale line.

The same company also received the contract from the West Side Railway Company to equip the Wyandotte street line. The wires for this road will be strung on iron posts instead of wooden ones, as are used on the Rosedale line. L. E. Myers, general manager of the Electrical Installation company, is in the city and will superintend the construction work in person.

OBITUARY

M. B. LEONARD.

It is with much regret that we note the death of Mr. Michael B. Leonard, superintendent of the telegraphic and electrical systems of the Chesapeake & Ohio Railroad. The cause of death at the early age of forty-two was a cancerous growth in the throat, upon which he was about to have an operation. He was born in Philadelphia in 1855, and was educated at St. Francis Xavier College, in New York City. It was his intention at one time to enter the Brotherhood. He had a splendid bass voice, and sang in the choir of St. Paul's, New York, as well as at Elmira. He developed a great taste for electricity and mechanics, and in 1872 entered the service of the Franklin Telegraph Company, going to the Western Union in 1873, the New York Central Railroad in

1877, and to the Erie Railroad in 1878, first, as chief clerk in the coal department and then as secretary to the general traffic manager. His next move was to the Chesapeake & Ohio as secretary to the general manager. Here his great executive ability soon displayed itself and in 1881 he was appointed superintendent of telegraphs to that railroad, a place he held down to the time of his death. He was also appointed superintendent of telegraph of the Newport News & Mississippi Valley Company, and of the Marysville & Big Sandy Railroad Company. He thus had complete executive and technical charge of the lines of these roads, comprising 2,500 miles of wire and over 100 commercial offices. He also had charge of the electric lighting and signal plants of the above companies.

Mr. Leonard had considerable success as an inventor. His block signal system was put into use on the C. & O. road, and he also brought out a car brake and an electrical heater. He was a skillful musician and for a number of years was organist at St. Peter's Cathedral, Richmond, the city in which he lived. He was familiar with several languages and had studied law with the idea of doing expert work in patent cases. As to his own electrical profession, it may be truly said that he was one of the most accomplished men in the field of railroad telegraphy, setting a brilliant example by his progressive policy and attitude toward all the new things. He taught electricity also at the Mechanics' Institute in Richmond. He was an influential member of the Association of Railway Telegraph Superintendents, and always one of the most loyal and interested members of the American Institute of Electrical Engineers. He was an early reader of The Electrical Engineer, which was often under obligations to him for suggestions and data; and his frequent purchases of electrical literature also showed his desire to keep abreast of the times. It is hard to part with a man so young, so talented and so amiable in all the relations of life, and the deep sense of loss felt by his relatives is shared by a wide circle of electrical friends and admirers. He leaves a wife and five children. His brother, Mr. John H. Leonard, is railroad editor of the "Mail and Express."

GALILEO FERRARIS.

THE cable announces the death last week of Prof. Galileo Ferraris, the eminent Italian scientist and Senator. The announcement will fill with grief all those whose good fortune it was to know Prof. Ferraris, and his loss is a heavy blow to science, to which he has contributed much valuable work.

Prof. Ferraris was born at Livorno-Marcellese in 1847, and was educated at the Royal Engineering School at Turin, graduating from the latter in 1869. At that time he had already published a paper on "The Telodynamic Transmission of Hirn," which was the first paper on this subject printed in Italy. Soon after this he was appointed assistant professor to Prof. Codazza, professor of technical physics at the Royal Italian Industrial Museum, and in 1879 he was elected professor of the Chair of Technical Physics of the University of Turin.

Prof. Ferraris had in the meantime devoted himself largely to optics, although by no means neglecting electrical work; and among the papers read by him in 1872 was one entitled "The Mathematical Theory of the Propagation of Electricity Through Homogeneous Bodies." His work on geometrical optics, published in 1877, was at once recognized as a standard, and was translated into several foreign languages. In 1881, acting under the stimulus of the Paris Electrical Exhibition, Prof. Ferraris, like many other physicists, found himself attracted more strongly towards electro-physical researches, and he represented the Italian Government at the International Conference on electric measurements, held in 1882. In 1883 he also represented his government at the Electrical Exhibition in Vienna.

The International Italian Exhibition, held in Turin, in 1884, was made memorable by the experiments carried on with the Gaulard & Gibbs transformers, under the guidance of Prof. Ferraris, and which gained this system the prize offered by the government for the best progress in the transmission of energy. Prof. Ferraris' memoir on this subject was a most valuable contribution to electrical literature.

But Prof. Ferraris is perhaps best known to American readers by his independent discovery of the properties of the rotating magnetic field, and their application to alternating motors. It is not necessary for us here to discuss the merits of Prof. Ferraris' claim to priority of discovery in this connection; for, that his work was independent and entirely original no one has yet disputed. The paper in which he first describes his experiments was read before the Royal Academy of Sciences of Turin, March 18, 1888, although his experiments, we are told, were carried out as far back as August and September of 1885. It is interesting to note in this connection that when Prof. Ferraris visited the United States in 1893, as a delegate to the International Electrical Congress, held in Chicago in 1893, he visited Mr. Edison at his laboratory, and in the course of conversation Mr. Edison inquired of Prof. Ferraris how he came to hit upon the idea of the rotating field. In reply Prof. Ferraris said that he was led to this discovery by his study and experiment upon polarized light, another instance of the influence which the study in one department of science may have upon another.

It was in 1886 that Prof. Ferraris organized the Electrotechnical School for Engineers in Turin, the first of its kind opened to the public in Italy. As stated above, Prof. Ferraris also represented the Italian Government at the International Electrical Congress at Chicago in 1893, and many American electrical engineers had the pleasure of making his acquaintance there. Prof. Ferraris had a most pleasing and engaging manner, and his bright and intelligent eye and imposing brow at once stamped him as a man of more than ordinary intelligence and mental endowment.

We may add that the sentiment of American electrical engineers was well expressed in the telegram of condolence sent at once on receipt of the news by the American Institute of Electrical Engineers, to the Italian Society of Electrical Engineers, of which Prof. Ferraris was the president.

MARRIED

BURKE-VEEDER.

The marriage of Mr. J. Burke, Jr., electrical engineer, of the firm of Herrick & Burke, to Miss Anna G. Veeder, daughter of Dr. A. T. Veeder, took place at Pittsburg, Pa., on Feb. 11, at 3 p. m. Hearty congratulations and many handsome presents were received from relatives and friends by the happy pair.

VOL. XXIII. NEW YORK, FEBRUARY 17, 1897. No. 459.

THE AGITATION FOR MUNICIPAL PLANTS.

SOME three years ago The Electrical Engineer, with the co-operation of Mr. Horatio A. Foster, the central station expert, made a collection and digest of all the information then obtainable as to the conditions under which municipal electric light plants in this country were operating. Every plant was written to, and all the data was carefully and impartially analyzed. The net result may be briefly summed up by saying that no real gain to the community was shown by the investment of public funds in commercial enterprises of this character.

The recent meeting of the Northwestern Electrical Association, at which several of the members were urgent and vehement in their protests against the extension of the municipal plant "craze," showed that in many parts of the country the competition of city plants had done serious injury, and is likely to do more, amounting sometimes to the confiscation of private capital that had been expended in good faith under public guarantees. Various remedies for the existing state of affairs were proposed, some sensible and some extreme, but it cannot be said that a definite plan of amelioration was adopted. In the mean time, it has seemed to us that what is really wanted is the intelligent discussion of the subject and that if the public is supplied with the facts it is not likely to go very far wrong, or in its enthusiasm over the new dream forget that such plants sometimes prove a burden and a curse. The position of The Electrical Engineer and of electrical papers generally is often misunderstood, and frequently misrepresented. As the advocates of an extension of electric lighting, they certainly would not stand in the way of anything which while promoting that would obviously benefit also their selfish, personal interests. But, having seen a great new art successfully built up by private enterprise, and witnessing the frequent rank failures of municipal plants for gas or electricity, they believe that both the art and the industry will advance more quickly in private hands than in public, and they are entitled to the expression of their opinions. The editors of this journal, with their fellows on other papers, have been abused like pickpockets for advising against expenditure of money raised by taxation in such enterprises, and have been accused of being allies of trusts and other bad things, but they do not see how their opposition could affect the movement for an instant, unless it were honest and based upon facts.

The present issue of The Electrical Engineer is largely given up to a collection of data bearing on the subject of municipal plants, and presented because it has evidently great interest and value at the present juncture. Perhaps the desire to be impartial will be seen in the space devoted to the special report made by Commissioner A. E. Winchester, of South Norwalk, Conn, a young electrical engineer of high standing and unblemished character, who, not satisfied with making a brilliant success of the plant in his care, has gone to great trouble to collect facts about the 300 other such plants now running. We print his report in full, so that our readers have before them the latest and most favorable word on the subject by one who is himself about as good a municipal commissioner for that work as can be found in all this broad country. In addition to this report, we give a mass of other current data and items, all of recent origin and later in date than the Winchester report, some of it throwing a searchlight beam upon the evils that beset plants of this kind under the conditions that may and do arise.

Mr. Winchester's report is frank and able, and we have no doubt that to those who have made up their minds that a municipal plant is the thing they want, it seems very strong. To us, it betrays a poor case, and does but confirm us in our suspicions as to the general ignorance on the part of municipal plant managers. In most instances, the balance sheet is decidedly unfavorable, and in many there appears to be no knowledge that such a vital factor as depreciation must be taken into account. We do not say that in this respect central station managers are shining examples. On the contrary, many of them sell their light too cheaply, because all the expenses have not been figured in. Still, the loss falls on a few, who have gone into the enterprise willingly, and not upon every member of the community that is already groaning under the burden of modern debt and modern taxation.

Even Mr. Winchester, staunch champion as he is of municipal plants, is slow to approve of them in the large cities, where various misguided people are now clamoring for them. In fact, he does not believe in them there, but, strong in the consciousness of his own acknowledged success and in his conviction that the countryman is sure to be more honest than the citizen, he thinks they are all right for the smaller communities. This may be so where private enterprise has not come forward, but why a small town or medium city should assume a burden and create new officials when it can abstain from doing so, will ever remain a mystery. Mr. Winchester presents a striking little table to show how a city by putting in its own plant may possibly save about $500 a year on a service of 100 arcs, but, as offsetting that, there are the figures, carefully worked out, which led Utica, N. Y., to drop the municipal scheme in order to save money, and there are also the figures submitted by disinterested experts to the citizens of Brookline, Mass., and quoted by us in extenso on Jan. 20, showing that arc lights from the proposed city plant would cost $123 per lamp per annum, or just about the same as those from private plants of the same size throughout the country. We confess that there seems to us to be no getting away from such figures, any more than we can get away from the statistics of bad city gas management in Philadelphia, as summed up by Mr. Bryce in a special section of his "American Commonwealth."

We have said before, and now venture to say again, that the question sums itself up into this: Does it pay? But that implies, after all, a good deal more than the meeting current expenses in which so many plants, whether private or public, fail to give satisfaction. If we look into the social and philosophical aspects of the thing, we find that it must necessarily lead to the creation of more and more officials, of a larger and larger debt, and of a greater and greater burden of management. Nearly all persons to-day who govern city affairs are congested with work and responsibility, yet the process of overloading them goes gayly on. And back of it lies a peril that has never been more sharply outlined than in the recent farewell words of Herbert Spencer: "When from the regulation of the workers of the bureaucracy we turn to the bureaucracy itself, and ask how it is to be regulated, there is no satisfactory answer. Owning in trust for the community all the land, the capital, the means of transit and communication, as well as whatever police and military force has to be maintained, this all-powerful official organization, composed of men characterized on the average by an aggressive egoism * * * must inevitably advantage itself at the cost of the governed. * * * Under such conditions there would be an increasing deduction from the aggregate produce by these new ruling classes, a widening separation of them from the ruled, and a growing assumption of superior rank." If this is what the municipal plant advocates want, it is devoutly to be hoped they will secure it for themselves only. If it is not what they want, why don't they stop before it is too late?

Returning to the specific subject under discussion, we would point out that there are various ways of protecting a city against undue charges. We need only refer to the work of the Massachusetts Commission, which can do, and actually does, much, to keep the companies in the narrow path of legitimate capitalization and fair treatment of their customers. It serves moreover as a barrier for the established companies against undue competition and against the wiping out of their property by the setting up of a municipal plant to do their business under unjust conditions that would ruin them. In Rhode Island, another plan has been adopted, namely that which limits a big company like the Narragansett, in Providence, to the payment of only 8 per cent. annually in dividends, all earnings above that going to the reduction of rates. The dividend allowed is small in proportion to the risks of the enterprise, but the public at least is taken care of.

The American public has been told that there are many municipal plants run successfully in Europe; it is so claimed, anyhow, and one of the reasons given is the superior virtue or morality of the authorities. This may be, though we doubt it, for there are other explanations besides the "unctuous rectitude" about which Mr. Cecil Rhodes has been twitting his English critics. In Europe there are a great many people of moderate means and abundant leisure to look after such plants for nothing save the local honor it confers on them. Here such a class hardly exists in this workaday Republic. Everybody is busy and will be until such a "class" is evolved, to do for all our communities what the town councils have done in old England or the selectmen in New. Even, then, there will be no gain of much account in running such enterprises, and we have still to be convinced that these plants in the old world pay as they are alleged to do. We know they don't in China, the ideal country of governmental and municipal control.

KEEPING TAB ON CITY LIGHTS.

APROPOS of the question of municipal lighting plants, it has been suggested that where such plants are not established, municipalities might keep a check upon lighting companies by taking independent records of the voltage and amperes of the current on the public lighting circuits. An instance of this kind, which has recently come under our notice, is presented by the City of Utica, N. Y. Here the contract between the municipality and the electric lighting company calls for the taking of a continuous record, on recording instruments, of the amperes and pressure maintained in the city lighting circuits, the instruments to be kept under lock and to be accessible only to the proper supervising city authorities. According to the contract, when the readings of the instruments show a discrepancy of more than 10 per cent. from the normal, a deduction is made from the contractor's bill, he being charged for deficiencies at a rate twice as high as the city pays. This system of check has been too short a time in operation to permit of determining its practical value, or as to whether it will prove satisfactory to either party to the contract. As, in addition to the deduction according to meter readings, the electric light contractors in Utica are also liable to deductions for lights out, it would seem to be hardly fair to mulct them twice for the same delinquency, for a light out would show on the record. On the whole we see no particular benefit to be gained by this scheme of recording. In the first place, the limit of variation allowed by the contract is one which no self-respecting lighting company would permit for any length of time on its circuits, since such a reduction of voltage at the arc lamp terminals would reveal itself at once by unsteadiness in the arc, and would be intolerable; or, in the case of incandescent lamps by a tremendous falling off in illuminating power. Besides, the ease with which this method of check can be circumvented is so patent that it seems fair to assume that it cannot have been suggested by any one practically acquainted with central station lighting, where customers' meters sometimes show queer readings. We shall watch the Utica experiment with some interest, but can hardly recommend it as meeting the objects aimed at.

"ONE-SIDED REPORTS."

IN reply to the recent editorial appearing in the American Machinist, in which our contemporary referred to a report on a comparative test between an electric and a compressed air mine pumping plant as being "one-sided," we fell back on the supplementary contribution made by Mr. Searing, the original author, as fully answering, in our estimation, all the criticisms which had been brought against the accuracy of his original contribution appearing in The Electrical Engineer. But it seems that the Machinist is still unsatisfied, and repeats, through some curious perversity, the charge of unfairness against us: "It is this very disposition to exalt and worship electricity," says our contemporary, "and to insist that it is the greatest force known to man, and should always be used in preference to any other, regardless of time, place and circumstances, that has more than anything else weakened the influence of electrical journals among impartial and disinterested engineers."

It is indeed interesting to learn that electrical journals have lost their influence among distinterested engineers for printing unsolicited articles about the application of electricity as a general substitute for other forms of motive power; but it is somewhat remarkable, we think, in view of this loss of influence, that engineers all the world over are slowly but surely applying electricity in situations where heretofore it had never been used, and particularly as a substitute for compressed air. There must surely be something wrong in the make-up of engineers who have ceased to be influenced by electrical journals, and yet will persist in doing the very things which those journals advocate. We are willing to admit the soft impeachment of a disposition to exalt and worship electricity, for we most assuredly think it to be the force, par excellence, to be applied wherever power is needed; but we must emphatically deny that we are blind partisans of the electrical, or any other cause.

Perhaps our contemporary also looks upon the substitution of compressed air locomotives by electric motors at Port Chalmette, La., described in our present issue, as the work of the bitter enemies of compressed air, but the owners of the road were perhaps best able to judge of what they considered adequate for their needs, and they decided that compressed air locomotives did not fill the bill. We believe there are a few things that compressed air may be able to do better than electricity, but they are so few that it is hardly worth while at the present day to enter into an extended study of the two, when considering the choice of methods involving power transmission or application. In the meantime we wish to say again here that we did not lift a finger or a voice, either to induce the Colorado company to supplant compressed air in its mine by electric power or the Port Chalmette people to throw out compressed air locomotives for electric locomotives. They did it all themselves—and then told us about it afterwards. We print the stories; that is our crime!

THE N. Y. EDISON CO'S ANNUAL REPORT.

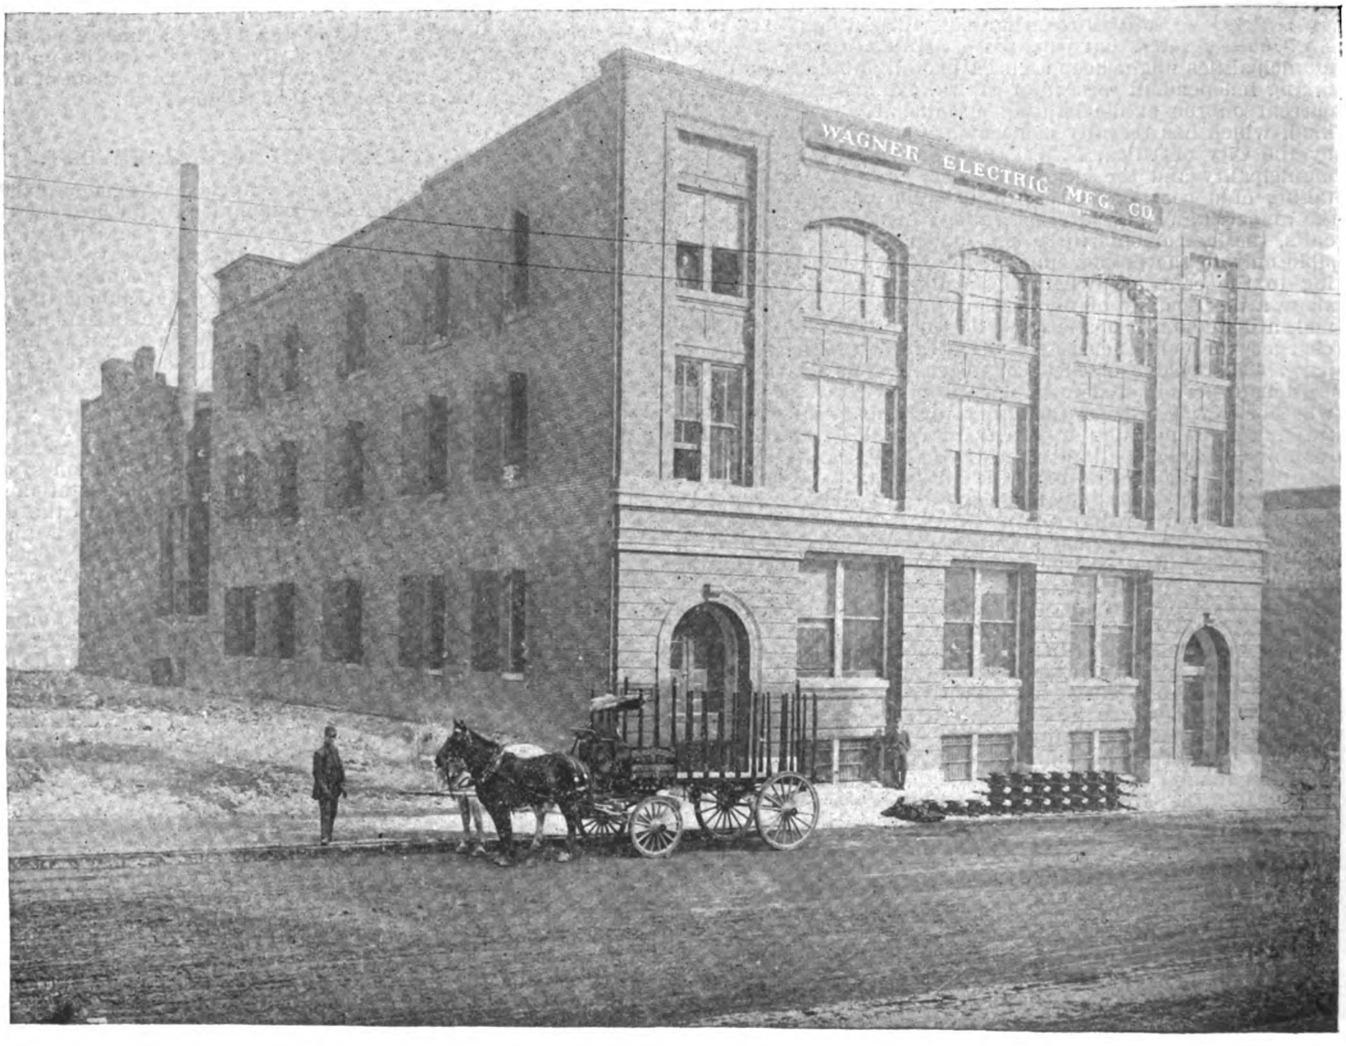
WE hear so much of the financial stringency existing among electric lighting companies at the present time, that it is refreshing to have placed before one a report of a year's operation of an electric lighting company, showing a good profit, and a substantial increase in business. Such is strikingly the case with the Edison Electric Illuminating Co., of New York, of whose annual report we give an extended abstract on another page. The gross station earnings in 1896 were $2,222,737.06, of which the low tension system claims as gross earnings, $1,771,229.83, with net earnings of $814,833.05, to which is added the income from the high tension system, bringing the total income of the company for the year to $960,156.94. These figures show that with nearly 80 per cent. of the income derived from the low tension system, the ratio of operating expenses (including both station and general expenses, but not depreciation charges), to the gross station earnings, is 52 per cent., which we believe is an exceedingly good ratio for this class of station work. There is no doubt but that this is due largely to the heavy motor load which the company is now carrying.

Reducing the entire output of the company's station to a common basis, the total capacity at the present time is 708,458 16 candle-power lamps, a figure which is not equalled, we believe, by any other company in the world. The increase during the past year amounting to 125,000 16 candle-power lamp equivalents, is proof enough of the vitality of the company and, we may say, incidentally, of the stability of electric lighting. In these days when the Welsbach lamp has been creating such unnecessary alarm among the electric lighting fraternity, it will be encouraging news to many to know that during the past year the New York Edison Company increased the number of its incandescent lamps connected by 27 per cent., and its arc lights by 8 per cent. But perhaps the most remarkable showing of all is that of the increase of electric motors connected to the company's circuits during the year—the motors aggregating no less than 15,930 horse-power, an increase of 36 per cent. over the preceding year. Here is a record that must at once strike the progressive station operator strongly with the possibilities of electric power as a profitable field for his endeavors. It is interesting to note that the actual number of motors installed during the year was 1,319 representing no fewer than forty-seven types of manufacture. It will be noted, with surprise perhaps by many that the New York Edison Company has in use among its customers over 8,900 meters, of which a large majority are of the Edison chemical type. In view of the alleged short-comings of this type of meter the proportion of errors to bills rendered, namely, 1-10 of one per cent., must be considered to be remarkably low. It is apparent, however, that the company is trying other types of meters. We commend to the attention of all electrical companies the New York Edison Company's method of providing a benefit dividend for its employés, depending upon the length and nature of their services, as a form of profit sharing. This is a most excellent means of raising the standard of work accomplished by employés, and of instilling into them the practice of looking upon the company's success as their own.

MISCELLANEOUS

THE WAGNER ELECTRIC MFG. CO. ST. LOUIS, MO.—ITS FACTORY AND PRODUCTS.

THE young men who, in the fall of 1890, were putting together a few "hand-made" fan motors in the repair shop of a local electric lighting company, were no doubt energetic and ambitious enough to believe that the fan motor business might eventually grow to generous proportions, but they hardly thought that in the course of a few years they would be at the head of one of the largest manufacturing concerns in this country, devoted exclusively to the manufacture of transformers and kindred specialties.



THE WAGNER ELECTRIC MFG. CO.'S FACTORY, ST. LOUIS, MO.

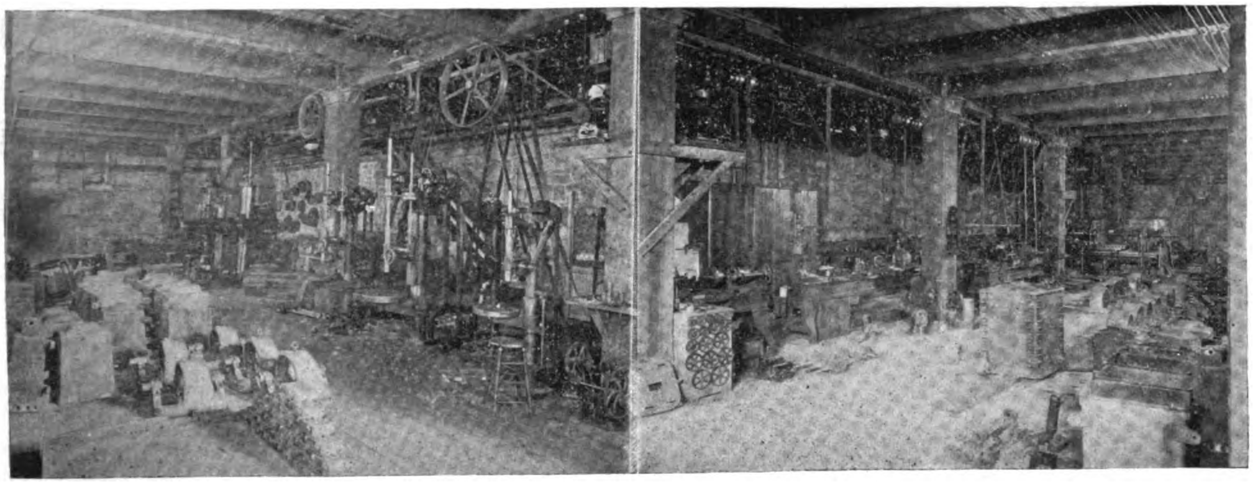
It was in the spring of 1891 that H. A. Wagner, in company with Fred Schwedtman, began the manufacture of alternating current fan motors on a small scale at 1822 Olive street, St. Louis. It was at the time when the single phase alternating current apparatus was considered "the thing" and the fan motors that would operate with such a current found a ready market. The Wagner motor gave great satisfaction, and, although imitated from the start, kept steadily in the lead. In August, 1891, the gentlemen named found it expedient to incorporate the Wagner Electric Manufacturing Company, with a capital stock of $25,000, half of which was paid in the way of machinery, tools, materials, etc. Mr. H. A. Wagner was elected president; M. E. H. Abadie, who had joined forces with Mr. Wagner some time previous, was made secretary, and Mr. S. B. Pike became treasurer.

During the first two seasons the small 1-10 horse-power fan motors were in such demand that the company could hardly turn them out fast enough and as early as 1893 found it necessary to secure the adjoining premises No. 1824 Olive street, thereby doubling their floor space with a corresponding increase in capacity. This gave the company somewhat of a breathing spell, enabling it to give attention to the growing demand for a somewhat larger motor. The 1-10 horse-power was accordingly changed to ⅛ horse-power and several improvements added, which made it the most efficient and reliable motor of that type then on the market.

It was at this time that the company secured some special switchboard work and a few months later built for the Missouri Electric Light and Power Company their large and now well known type of switchboard. The building of this and other boards marked the entrance of the Wagner company into the field of building switches and switchboard devices, especially those adapted for alternating current work, and in which it has steadily progressed, furnishing to-day a complete line of switches and switchboard accessories, acknowledged as of the highest grade and noted for their excellent workmanship, accurate construction, fine finish and ingenious disposition of the several parts.

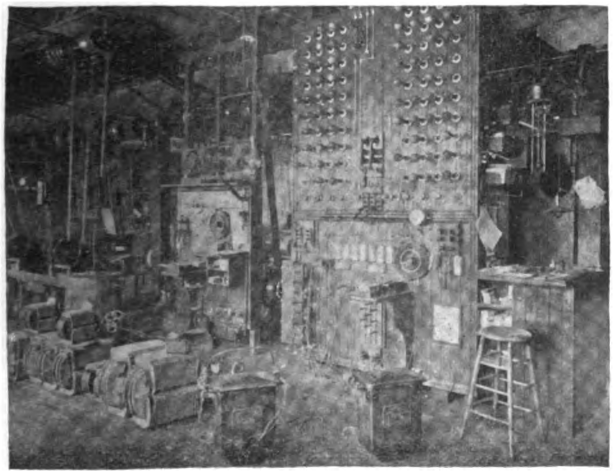
The constant increase in business during the fall of 1892 and spring of 1893 which necessitated the increase in shop room, also showed the advisability of increasing the capital stock in order to keep the business and financial ends in proper balance. Accordingly in June, 1893, the present stockholders arranged to subscribe sufficient funds to increase the capital stock to $100,000, part of the arrangement being that the offices should be held by stockholders only and the management remain in the hands of the original incorporators. At a stockholders' meeting S. M. Dodd was elected president; Jas. W. Bell, vice-president; S. B. Pike, secretary and treasurer, Mr. H. A. Wagner was made general manager, E. H. Abadie, manager of sales department, and Fred Schwedtman, superintendent. These officers have not been changed since. It was only natural that with the constantly growing business the company's quarters on Olive street soon were inadequate to give room for additional tools and workmen, and it was decided to secure a building and ground that would permit of gradually increasing the size of factory for several years to come. Accordingly in August, 1893, the lot 2017-2019 Locust street, extending through to St. Charles street, was acquired.

By this time the repairing, operating and testing of the various transformers sent in by the company's customers had developed to such an extent as to show the desirability of entering the field as manufacturers themselves. One of the stock arguments of the direct current advocates against the use of alternate current apparatus at the time was, that the constant leakage in transformers on a circuit would soon eat up what saving there might be in the first cost of line wire.



Views of the Main Machine Shop.

The Wagner company attacked the problem intelligently and the result was its type A transformer, which at once took a leading place owing to its high efficiency, regulating properties, and other desirable features. Much against its wishes the company was compelled to put on the market its type B transformers, which in make-up were similar to the type A, and while not of the same high grade, were still equal and often superior to most of those built at the time. In the fall of 1894 the company brought out a still later type, designated C, in which were embodied the results of all the latest experiments, resulting in a transformer of an efficiency and with a regulation hitherto unattained. These transformers found a ready sale, as by this time central stations had learned by expensive experience that in a transformer the first cost is not the only consideration. Saving in operating expenses had become the watchword, and the low efficiency apparatus had to go.



A Corner in the Testing Room.

The type C transformer satisfied the central station men, but the Wagner company, believing that still greater improvements could be made, brought out in January, 1896, a still later line, type D, which not only showed still higher efficiency and better regulation, but also contained a most ingenious fusing device. This with the mechanical construction of the coils as well as the arrangement of the magnetic circuit, makes it probably as near an ideal transformer as can be constructed without going so far as to make its manufacture on a commercial scale impracticable.

Many more conservative concerns would perhaps be content to let well enough alone, but the Wagner company, always on the alert for improvements, is now experimenting with and about ready to place on the market a new and distinct line of transformers of a special type for stations desiring the highest obtainable efficiency and who are willing to pay a reasonable price for first-class apparatus of that kind.

THE FACTORY.

Our illustrations show the present location of the company's works, with a few interior views of the several departments. As already stated these premises were secured in August, 1893, but at that time only contained a building 40 x 73 feet, four stories high, fronting on St. Charles street. This answered the purpose for a few years, but in 1896 the new building on Locust street was added, taking up a space of 120 x 73 feet, also four stories high, thus covering the entire ground from Locust to St. Charles street. In planning the new building, provision was made for adding three additional stories when necessary.

A View in the Assembling Room.

The building is constructed and arranged in a most admirable manner, making it thoroughly modern in every respect. All machinery is of course driven by electric motors, supplied with current from the local lighting company's power circuits. The various tools are grouped, generally three or four of a kind, about a short countershaft driven by a separate motor. This arrangement has been found more economical than the practice, advocated by some, of supplying each tool with its motor, in which case the efficiency is no doubt much lower than where the motor has a fair load at all times. The arrangement as practiced in the Wagner factory gives ample flexibility, and as current is available during the entire 24 hours, any one or more departments can be run overtime when required.

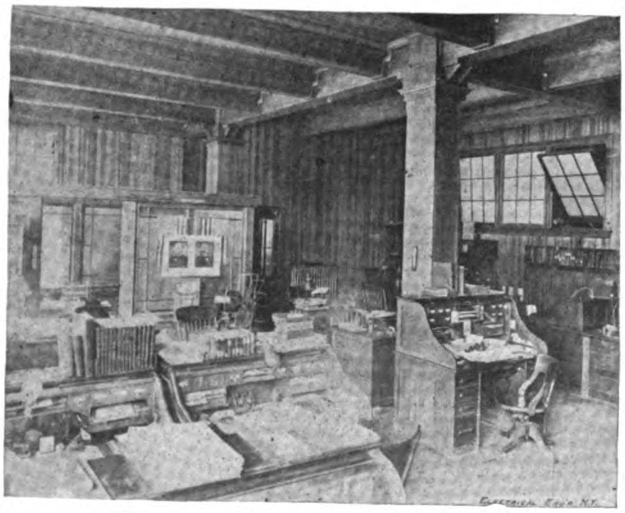
In addition to the necessary power circuits, the factory is supplied with alternating currents of various frequencies and pressure as well as with continuous currents of 220 and 500 volts, so that any desired test can be made on transformers, motors, switches, etc.

A Part of the Shipping Room.

The building is equipped with the latest appliances in the way of heating and ventilating apparatus, intercommunicating telephone system, fire extinguishers, and, in fact, all those details that enter into the equipment of a modern, up-to-date factory.

ALTERNATING CURRENT MOTORS.

With the continued increase in the number of alternating current stations came naturally a demand for efficient motors of the small sizes, suitable for use with such currents. This led the company to continue its experiments in that direction and in the early part of 1895 it had several motors operating in a very satisfactory manner in its shops, driving machinery.

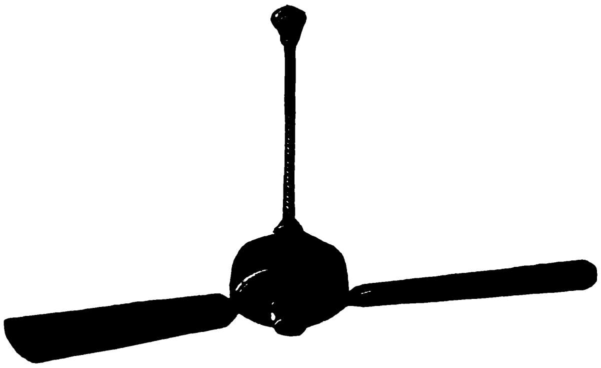


A Corner of the Offices.

On account, however, of the somewhat complicated mechanism of the starting device the company did not deem it advisable to place the motor on the market at that time. These motors have now been so improved and simplified that even an inexperienced operative can handle them without trouble and they are now practically ready to be delivered in sizes of 3, 5 and 10 horse-power. They are of the non-synchronous, single phase type, operate smoothly and are in every respect as reliable and efficient as the direct current type.

ALTERNATE CURRENT CEILING FANS.

Within the last few years the small desk or bracket fan motor seems to have been in great danger of being gradually driven from the field by its more effective successor, the revolving ceiling fan, and in order to supply the demand for this style, the Wagner company last fall began the manufacture of an alternating current ceiling fan and motor which bids fair to outstrip any of its rivals on account of its extreme simplicity. It is of the induction type, and having neither commutator nor brushes, avoids the most vulnerable parts usually found in apparatus of this kind. It runs at the same speed as its prototype of the direct current class and consumes only from 100 to 125 watts, which is certainly as little as can be expected from motors of this kind.

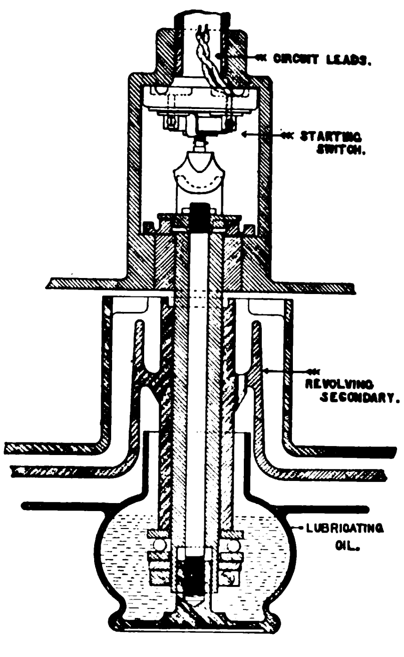


Alternating Ceiling Fan.

The motor has only one journal, and that is ball-bearing and submerged in oil, as shown in the accompanying illustration. The whole apparatus is claimed to require absolutely no attention, except starting and stopping when desired, for at least two years, that being the length of time the oil is assumed to last before becoming too dirty. This fan motor was exhibited at the last convention of the Northwestern Electrical Association, and elicited much favorable comment on the part of those in attendance.

DIRECT CURRENT MOTORS.

In June, 1894, the company placed on the market a line of direct current motors in sizes of from one-fourth to ten horse-power, believing that a demand existed for a first-class motor of the sizes mentioned. These motors were all of the four-pole type, had self-oiling bearings, and, what was then somewhat of a novelty, rigid, non-shiftable brush holders. Like the transformers, the motors were of a higher grade than many then on the market, and even to-day are not surpassed



Section Showing Starting Switch and Method of Lubrication of Ceiling Fan.

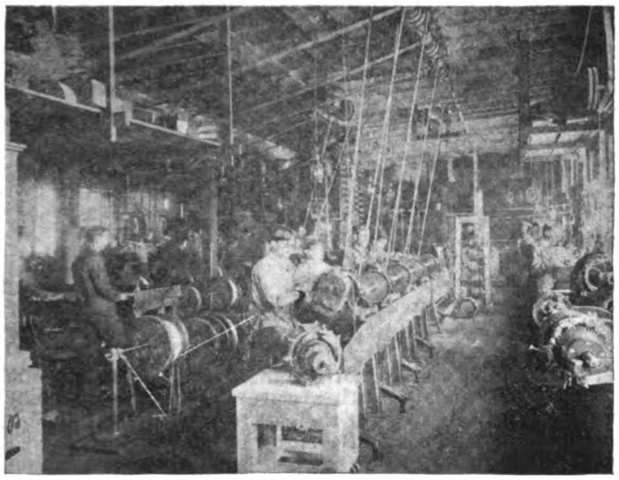
in points of efficiency, regulation and durability. Their fate was similar to that of the high-grade transformers. Power users were not alive to the importance of having a highly efficient motor, and central station people were more or less indifferent, especially when the current for the motor was paid for on a meter basis. The Wagner Company, not caring to meet the competition of the cheaper grades, did not push the sale of these motors to any great extent. The company is contemplating putting them again on the market, having enlarged the line so as to include sizes up to 25 horsepower.

HOW THE WAGNER TRANSFORMER IS MADE.

To follow the making of a Wagner transformer throughout its various details, from the proper determination of its dimensions in the laboratory to the shipping platform, would require more space than is within the scope of this article. A brief mention and a few illustrations, however, of the principal steps during its manufacture cannot fail to be of interest to our readers.

In the winding room the coils are wound on winding machines specially designed and made by the company. A row of these winding lathes is shown in our illustration; each row is driven by a motor, a friction clutch enabling the operator to start and stop his lathe at will. Counters showing the number of wire turns are fitted to each lathe, it being, of course, important to have the exact number of turns on each coil.

While in process of winding the coils are being saturated with a special insulating compound, which soon hardens and makes the coil absolutely impervious to moisture. The compound will not soften under any degree of heat that the coil will be subjected to, and being in itself a high insulator, short circuits or electrical leaks are impossible. As soon as wound, the coils are placed on trucks and run into a baking oven, where the last degree of moisture is driven out. The oven is so arranged that the "green" coils enter at one end and leave, thoroughly dried, at the other. From the oven the coils are delivered to the mounting benches, where they are carefully finished and provided with additional insulation, so as to receive the iron core.



Winding Armature, Field and Transformer Coils.

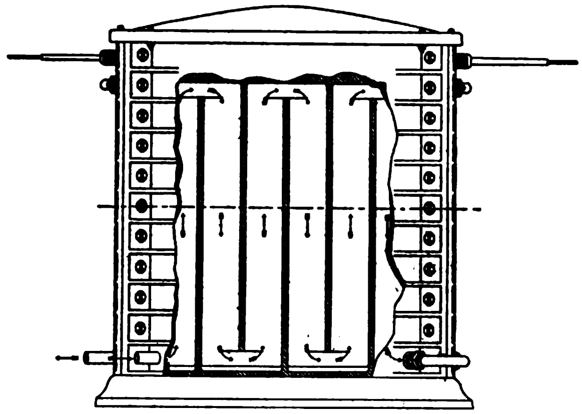
The core is built up of soft iron punchings, made of the thinnest iron obtainable, and carefully annealed before use. In the selection of this iron the company exercises the utmost care, each lot being tested for permeability, hysteresis and magnetic qualities in general. The company has gone into this question of iron losses very thoroughly, and it was found that some kinds of iron which at first showed up favorably in a transformer core would in the course of a few months show an increase in the iron loss of as high as 25 per cent., and in some cases on record the losses gradually increased to nearly 100 per cent. Iron of this kind is, of course, utterly unfit to go into a transformer core.

The transformer, with its coils and core having been assembled, is next sent to the testing board, carefully checked as to winding and tested for insulation and iron loss. If found "O. K." it is returned to the mounting bench and completed, after which it goes once more to the testing board to receive a rigid final test, of which an accurate record is kept for future reference. The transformer is now ready to be cased and boxed for shipment. Owing to this rigid system of inspection and testing it is, of course, improbable that a defective transformer leaves the factory.

These transformers are at present built in sizes of from 250 watts to 100 k. w. for lighting circuits, as well as in similar sizes for power purposes. For two and three-phase work the 100 k. w. size is the one most usually furnished.

HIGH TENSION TRANSFORMER WORK.

Long distance electric transmission at high tension, by means of which otherwise unavailable water powers are being rapidly utilized all over this country, as well as abroad, has opened a new field for the static transformer. Current generated by single, two-phase and three-phase machines at pressures of from 500 to 2,000 volts, to be economically transmitted such distances as twenty and thirty miles, must be raised to 5,000, 10,000 or 20,000 volts, dependent on conditions. Step-up and step-down static transformers for such service equally durable with low tension transformers were promptly put on the market by the Wagner Company. Among the important installations of this kind of apparatus put in by the Wagner Company are the following:

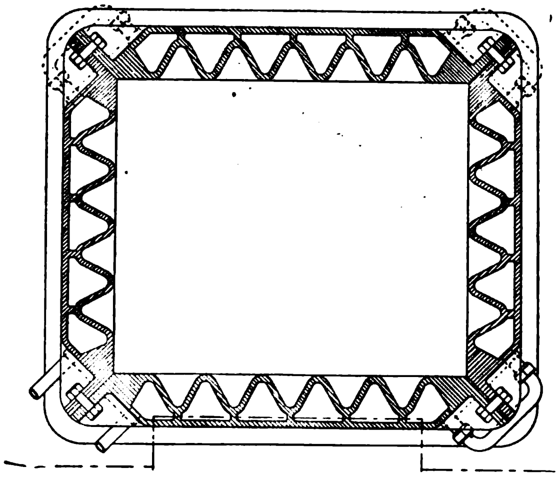


Water-Jacketed High Tension Transformer. Vertical Section of Case.

Riverside, Cal.—Municipal plant, 22-mile, 3-phase transmission, at 10,000 volts, 600 k. w. Colton, Cal.—Municipal plant, 18 miles, 3-phase transmission, at 10,000 volts, 50 k. w. Lachine Rapids Hydraulic and Land Company, of Montreal, 3-phase transmission, at 5,000 volts, 1,000 k. w. Edison Electric Light and Power Company, Brooklyn, N. Y., 200 k. w., 4,000 volts. Missouri Electric Light and Power Company, of St. Louis, 600 k. w., 20 miles, single phase, 5,000 volts. Webster, Mo.—22 miles, 400 k. w., 4,000 volts. A. A. Tibbe, Washington, Mo., 10 miles, 5,000 volts, 60 k. w.

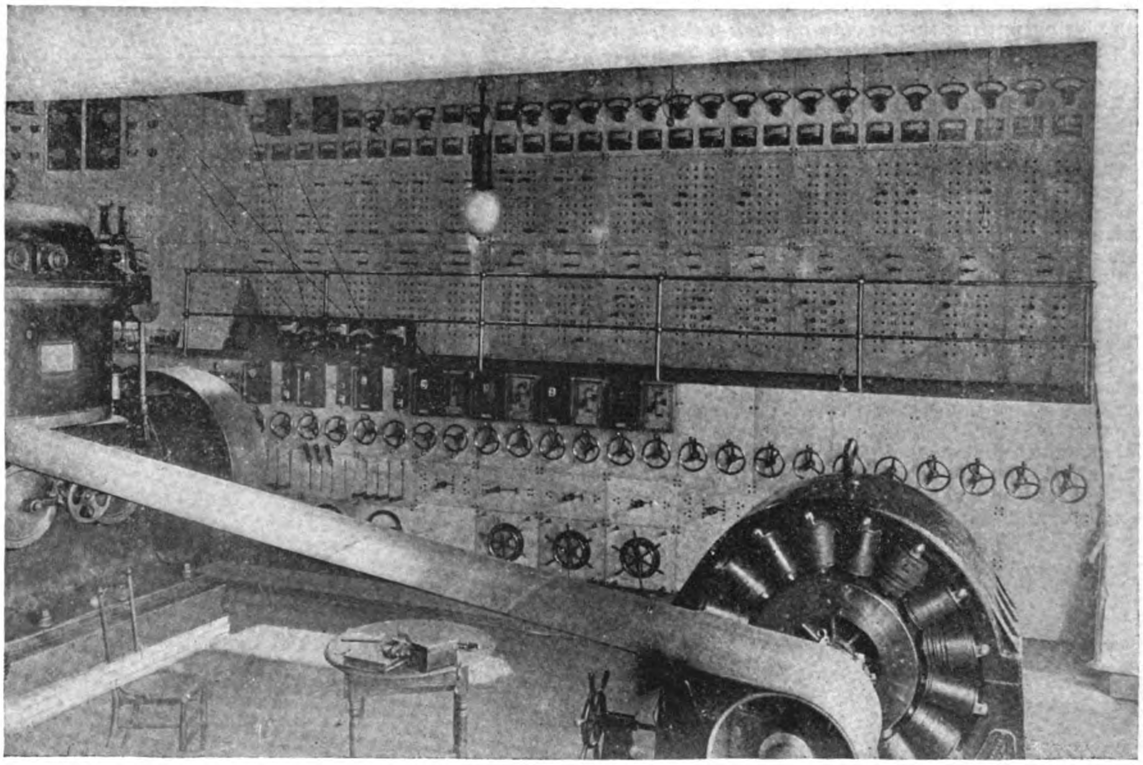
Static transformers for this kind of work are built in four types by the Wagner Company: (1) Self-cooling dry, (2) self-cooling oil filled, (3) air blast dry, (4) water jacketted oil filled.

The first and second forms meet the requirement for isolated substations where no regular attention can be given transformers. The third and fourth types are for use in large installations where station attendants are provided. The system of erection with (3) is to place the transformers over air ducts having blast outlets immediately under each transformer. These ducts converge to one large blower, of capac-



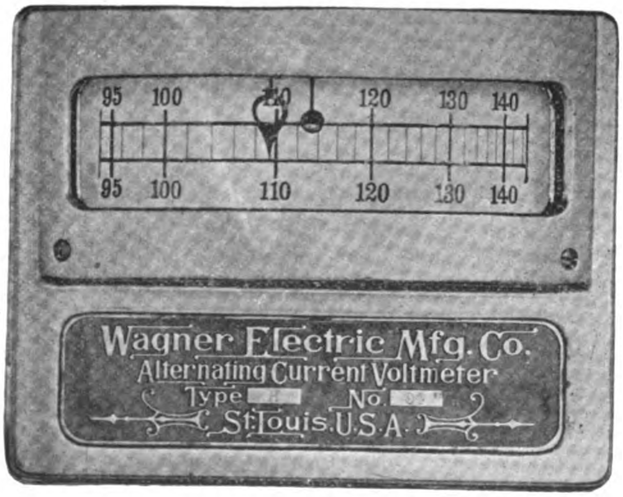
Water-Jacketed High Tension Transformer. Horizontal Section of Case.

ity sufficient to ventilate the entire bank of transformers. The blower is driven by a single-phase, self-starting induction motor, either belted or directly coupled to the blower shaft as conditions warrant.



Wagner Switchboard in Station of Missouri Electric Light Co., St. Louis.

With type (4) a gravity water-head of about 15 feet is provided, each transformer case being coupled to the supply pipe. As shown in the illustration, the water-jacket is so channeled that the water supply passes vertically up and down the transformer case 15 or 20 times before finally making its exit from the discharge pipe. Transformers of this type are so designed as to be self-cooling up to about three-fourths load, and only require the water circulation through the heavy load hours of the day. The volume of water required for proper cooling is about two gallons per 100 k. w. per minute.



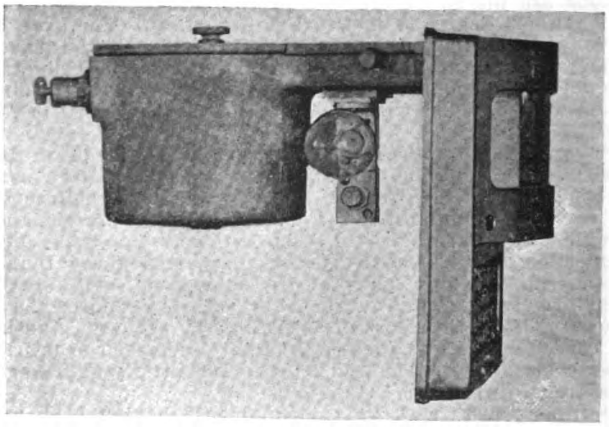
Switchboard Instrument. Front View.

The oil used for ventilating and insulating service in connection with all high-tension transformers is one which is clean, of light weight, and of exceptional insulating quality. Heat, instead of deteriorating it, as is the case with the majority of oils, improves its insulating quality.

In construction, all high tension transformers have the materials so disposed as to allow free circulation of the ventilating medium, at the same time avoiding magnetic leakage and maintaining high efficiency.

In high tension work this company is prepared to build static transformers in such capacities and at such pressures as required by the service, in units up to 500 k. w. for single phase, two-phase or three-phase transmission.

TYPE H. INSTRUMENTS.



Switchboard Instrument. Side View.

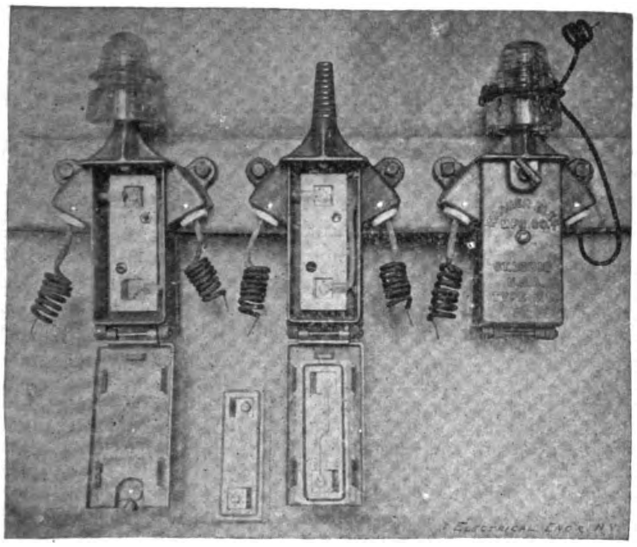
In the design of these instruments, which include ammeters, voltmeters and indicating watt meters, the company's object was primarily to meet the call for a sensitive, accurate and absolutely dead-beat alternating current switchboard instrument. The claim made for them is that they are the only instruments in the market satisfactorily meeting these requirements. They are decidedly novel in design, and so designed that the scale only is seen on the face of the switchboard, the case proper containing the working parts, being behind the board.

The case is filled with a light, highly insulating, transparent oil, completely submerging the working parts. Mounted on a vertical shaft, which carries the armature and pointer, are aluminum vanes, the resistance of the oil to these vanes forming the deadbeat feature. The vertical shaft, moving in jewel bearings, operates without any frictional error, which is unavoidable with horizontal shafts. The resisting element to the deflecting torque consists of a pair of opposing springs of such strength that every deflecting pressure or current causes an absolutely accurate position of the indicator on the scale. The latter is plotted on opal glass, bent to an arc of 7-inch radius, and covers 70 degrees. Two 8 candle-power lamps placed immediately behind the glass serve the double purpose of illuminating the scale and lighting up the rear of the switchboard.

The instruments are practically non-inductive, hence operate interchangeably with any frequency. Although primarily designed for alternating currents, the line complete includes instruments for direct current work, superior accuracy, sensitiveness and attractive mechanical design being the points aimed at.

THE "XL" CUTOUT.

The "XL" cutout embodies features of design especially attractive to the central station man. The case has a pin for the insulator cast upon it, thereby avoiding the extra insulator bracket usually required. The opening of the lid of the case serves to draw the upper half of the block, which carries the fuse, out of circuit, thus avoiding all danger to the lineman in re-fusing. The porcelain parts are interchangeable, the fuse portion sliding out easily on removal of a single screw in the cast iron cover. The cutout will successfully take care of short circuits on any voltage up to and including 5,000, being designed to take care of 30 k. w. in line energy. The insulation against grounds is especially high. The case is absolutely waterproof, and will withstand a ground test of 10,000 volts in any kind of weather.



"X L" Cut-Outs.

THE BUSINESS OF THE COMPANY.

As already indicated in the beginning of this article, the business growth of the Wagner Electric Manufacturing Company has been steady and uniform, showing an increase of about 60 per cent. for each year over the preceding one. Even with the dull times of 1896 the actual gain in sales over those in 1895 amounted to 55 per cent., which would seem to indicate that a superior product is appreciated by the consumer, and that the demand for a better electrical apparatus is increasing yearly.

During 1895 the Wagner Company made several sales of its fan motors and transformers in France and Switzerland, and has since added to its foreign territory Japan, the Philippine Islands and Cuba. Its Canadian and Mexican trade has for several years been quite extensive. The company's entire foreign trade has shown a remarkable increase during the past year, the gain of that year over 1895 amounting to just 600 per cent.

The Wagner Company has several branch offices. In New York they are located at 1103 Havemeyer Building, with offices in charge of Mr. John Mustard, sales agent, with Mr. A. H. Mustard, assistant, in charge, and Mr. King. In Boston their branch office is at No. 620 Atlantic avenue, and is in charge of Mr. G. H. Kimber, sales agent. In Philadelphia, Mr. John Mustard, 1000 Betz Building, looks after the company's interests, as sales agent, assisted by Mr. D. H. Garrett.

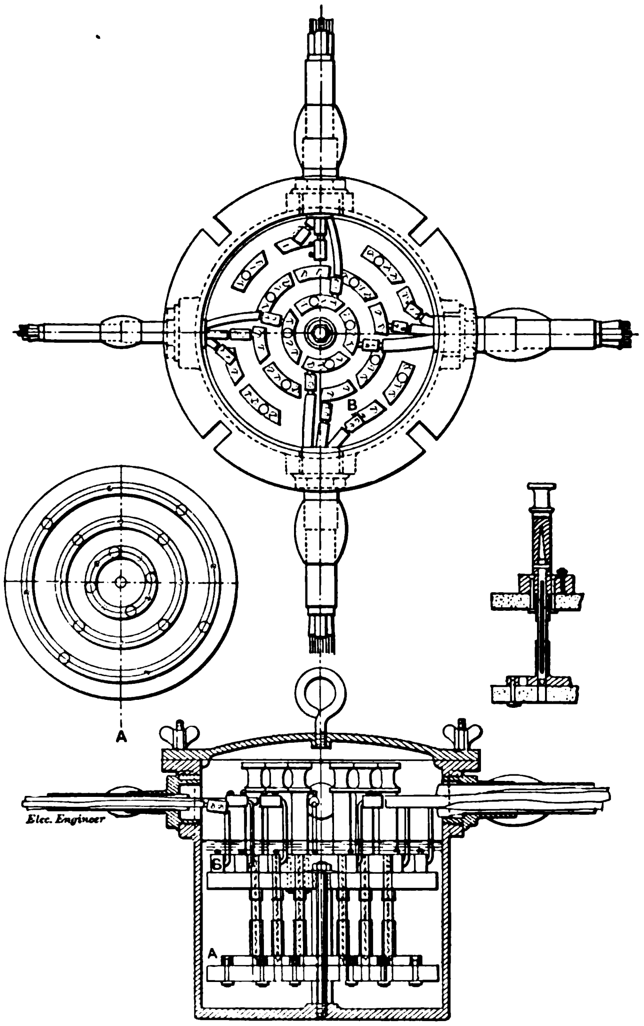
In addition to these branch offices the company has several agents representing it for the sale of its products. These are the Central Electric Company, of Chicago; the Western Electric Company, Chicago and New York; the California Electrical Works, San Francisco, exclusive agents for the Pacific coast, and the People's Electric Company, Madison, Wis., agents for the Northwest.

THE CLOOS JUNCTION BOX FOR HIGH POTENTIAL CIRCUITS.

With the advent of the high tension alternating current underground systems, there has been made apparent the necessity of an improved method of making service connections to the feeders in the manholes.

While the method of perfectly wiped joints gave high insulation it made an insulation test of the feeders proper impossible as all branches fed by a given feeder had to be made part of this test. When the insulation was low on a feeder to locate defective parts necessitated the cutting of a number of joints in order to divide the cable into sections; this caused the whole section fed by that feeder to be in darkness from the time the cable was disconnected until the renewal of the broken joints.

It was very evident that some method was urgently required by which a permanent and high insulated service connection could be made, permitting the cutting out of this service wire without disabling the feeder and at the same time allowing easy access to the ends of the cables for cutting out and testing.



The Cloos High Tension Alternating Current Junction Box.

This has been accomplished, and in a very successful manner, by Mr. Jacob Cloos, electrical engineer of Pabst Heat, Light and Power Plant, of Milwaukee, Wis., by means of a junction box which has been in successful operation for some time on the 2,400 volt underground system at the above plant. This box as shown in the accompanying engravings consists of a cast iron box of cylindrical section. The top of the box is made water tight by means of a lead gasket and holding down screws. The feeder and mains are conducted into the box through brass bushings screwed in with a lead gasket, the lead cover of the cable being joined in the bushing with a wiped joint, making the box absolutely water tight.

Within the box are two marble plates about 4 inches apart. Upon the top plate are mounted brass terminals arranged in concentric rows for two or more wire cables connected by special terminals and fuses to the various cables. Upon the lower plate are two or more continuous brass rings, directly under the brass terminals on the upper plate. The lower rings are made alive by pushing spring plugs through holes in the terminals connected to the feeder into corresponding holes of the lower plate. Any cable leading out is connected to the feeder by similar plugs leading from the rings to the cable terminals above. The boxes are filled with oil, thus forming a water proof joint of high insulation and one easily accessible.

These boxes have been operated when entirely submerged under water and no difficulty has been experienced whatever. They have demonstrated their great value on several occasions by enabling repairs to be made and faults to be located on sections, without interfering in any manner with the rest of the system connected to feeders.

The above described junction box was originally designed for underground work only. Since then the inventor has designed another box on the same principle for overhead construction covering all the essential points and features of the box described above.

EDUCATIONAL

THE STEVENS INSTITUTE OF TECHNOLOGY'S 25th ANNIVERSARY.

As already announced in these columns, the Stevens Institute of Technology will celebrate its 25th anniversary on February 18th and 19th. Preparations are now being actively pushed to make the event a memorable one in the annals of the Institute. The banquet to be held at the Hotel Waldorf, New York, will be attended by several hundred graduates and undergraduates, as well as by many representative men in the engineering and mechanic arts, who have been invited to be present.

The exhibition of the work of the Institute's graduates promises to be one of the most attractive features of the celebration. The applications for space will tax severely the capacity and facilities of the Institute, as many of the exhibits will be shown in actual operation. The exhibits range from single devices to a complete electric light plant operated by gas engine. The latter is the invention of Mr. F. P. Nash, a graduate of the Institute, who bears the distinction of being among the five most prolific inventors in the United States, there being over 200 patents issued to him, on various types and details of gas engines, water meters, etc. The exhibition of photographs, working drawings of apparatus designed, and works carried out, by graduates, will also be of more than usual interest and value.

The present occasion seems a fit one to call attention to the needs of the Stevens Institute of Technology, whose work has year by year outrun its facilities. The founder of the Institute, Edwin A. Stevens, Esq., originally bequeathed a plot of ground and $150,000 for the erection of a building "suitable for an institution of learning," together with $500,000 as an endowment fund. From this amount the U. S. Government in 1870 took about $45,000 as a collateral inheritance tax. As the courses of the Institute were broadened, increased funds were required for equipment, but as these were not available from the income of the endowment fund, the worthy President of the Institute, Dr. Henry Morton, has in the past generously provided the increased facilities placed at the disposal of students, out of his private funds, and we learn that in connection with the coming anniversary he has already transferred to the Trustees of the Institute 1,000 shares of the stock of the Texas Pacific R. R., to be held by them until, by reason of its increased value and other donations for the same object, a fund will be made up adequate to the erection and maintenance of a much needed new building, for which a considerable amount has been already raised by the Alumni Association.

This stock is to-day worth $10,000, but, representing as it does a property of great intrinsic value, may be reasonably expected to appreciate largely within a moderate time. This idea of presenting to the Institute something of growing value, which may be likely to advance so as to meet the enlarging demands of the future is, we think, worthy of imitation.

CHICAGO SCHOOL OF ELECTRICITY.

At the regular fortnightly meeting which was held at the rooms of the Chicago School of Electricity on Thursday evening, February 4, Mr. James Wolff, of the New York Insulated Wire Company, gave a very interesting talk on the subject of the manufacture of insulated wire. Mr. Wolff proved thoroughly conversant with the various processes which copper wire has to go through in the course of its manufacture. The audience, which was large, paid marked attention to the discourse, and on its conclusion Mr. Wolff received its warm thanks for his instructive lecture.

SOCIETY & CLUB NOTES

AN IMPORTANT FORTHCOMING EXHIBITION IN NEW SOUTH WALES.—A CHANCE FOR MORE EXPORT TRADE.

On June 26 a very important exhibition is to be opened in the Exhibition Building, Prince Alfred Park, Sydney, N. S. W. The exhibition will remain open during the months of July and August. It is intended to embrace engineering in all of its branches, and the exhibits will consist of raw materials, manufactured articles, machinery and models (in motion and otherwise), drawings and photographs of all kinds relating to scientific, mechanical and educational works, in classified sections. There will be no charge made for space allotted, but the Executive Committee reserves the right to limit the space of each exhibitor. The object of the exhibition is solely the advancement of engineering science and the promotion of a general and practical education therein. It will be non-competitive.

It is scarcely necessary to point out the advantages which will accrue to exhibitors in bringing their manufactures in such a prominent manner before the general public.

The exhibition will be under the patronage of the Governor, Viscount Hampden.

Among the various groups we notice Group IV. Prime Movers, comprising steam engines, gas, electric, hydraulic, hot air, etc., water wheels, turbines, windmills, etc., steam generators, accessories of engines or boilers.

Group V. comprises machine tools, hardware, edge tools, cooking appliances. Group VI. comprises railway, tramway and vehicular appliances, and embraces rails, switches, signaling apparatus, locomotives, goods wagons, carriages, etc., tramway cars, rails, permanent way, brakes, couplings, ticket checking apparatus, bicycles, tricycles and auto-cars.

Electricity, Group IX., occupies an important place and embraces generators, conductors, testing and measuring apparatus, telegraph and telephone apparatus, electric lighting apparatus, electro-metallurgy and electro-chemistry, transmission, distribution and utilization of power, lightning conductors, electro-thermic apparatus, and electro-medical apparatus.

There are important groups also covering hydraulic machines, refrigeration, chilling and dairying appliances, educational appliances, drawings and photographs.

The exhibition will be very comprehensive, and as those held in 1883 and 1886 proved exceedingly successful, it is expected that this exhibition will be a greater success than the others. The Executive Committee has appointed Mr. Edward Noyes, of Sydney, its representative in Europe and America for the purpose of obtaining exhibits. All communications on the part of intending exhibitors may be addressed to him, care the Standard Air-Brake Company, 100 Broadway, New York, and they will receive immediate attention.

This opportunity gives American manufacturers of electrical and engineering apparatus an excellent means of displaying their wares in Australia as the exhibition will be very largely attended. It opens a favorable field for leading the way to sales in that enterprising country.

LIGHTING AT THE CYCLE SHOW.

The cycle show, held in New York City last week, proved to be in reality two shows, there having been, in addition to the display of bicycles, a display of electric lighting effects. Many exhibitors spent more money for signs than for rent and other incidental expenses.

In addition to the regular house lighting of 5,000 16 candle-power lamps, a special service was taken from the United Electric Light and Power Company for the sign lighting and extra illumination in the booths. This extra lighting amounted to more than 16,000 lamps evenly distributed over the three floors. All the work on the extra lighting was done under the direction of Marcus Nathan, and the consulting engineer of the board, Frank Patterson.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION will hold its annual convention at Niagara Falls, N. Y., during the last week in May or early in June.

REPORTS OF COMPANIES

ANNUAL REPORT OF THE NEW YORK EDISON CO.—INTERESTING FIGURES.

THE annual report of the Edison Electric Illuminating Company, of New York, has just been issued and shows a remarkably healthy growth in the business of the company during the past year.

We give below an extended abstract from the report of the first vice-president, Mr. R. R. Bowker:

The year 1896 has continued the good record of this company for successful and profitable results. The increase in installation has been unusual, reaching 125,000 16 candle-power equivalent, or 28 per cent., largely in power business, this increment alone exceeding the total installation of any other electric supply company in this city. the gross station returns have increased 14⅜ per cent., while the general and operating expenses have increased but 7½ per cent.

The following table shows the net increase in the several classes of installation and in earnings in the past year, reckoning a standard arc lamp as the equivalent of ten 16 candle-power incandescent lamps and a horse-power in motors as the equivalent of fifteen 16 candle-power incandescent lamps:

	1896. Dec. 31.	1895. (Jan. 1, 1896.)	Increase in 1 year.	P. C. Inc.
No. customers ...	6,562	5,705	857	15
No. inc. lamps...	279,405	218,877	60,528	27
No. arc lights....	3,225	2,964	261	8
No. motors, h. p...	15,930	11,640	4,290	36
Totl equiv. 16 c. p..	560,342	434,834	125,508	28
Gr's sta'n ret'ns†.	$1,771,229.83	$1,544,822.78	$226,407.05	14⅜
Gn. & op. exp's*.	836,396.77	759,472.71	56,924.06	7½
Net sta'n returns†	934,833.02	785,350.07	149,482.99	19
Prop. exp's* to grs†	47%	50%		

These figures include only Edison central station direct service.

The following table gives the figures inclusive both of Edison central station service and of isolated plant installations supplied from the Edison stations during minimum hours or for emergencies:

	Central Station Service.	Isolated Plant Service.	Total Service.
Customers	6,562	72	6,634
Meters	8,441	91	8,582
Incandescent lamps	279,405	64,705	344,110
Inc. lamps, 16 c. p. equiv.	286,532	68,447	354,979
Arc lamps, number	3,225	889	4,114
Arc lamps, 8 ampere equiv.....	3,486	889	4,375
Motors, h. p.	15,930	1,142	17,072
Total equivalent	560,342	94,467	654,809

These figures do not include those of the high-tension companies operated under the supervision of this company and constituting practically the high-tension division of this company. These companies had on their station service December 31, 1896, 29,964 incandescent and 2,334 arc lights, and 23 horse-power in motors, or an equivalent of 53,649, which, added to the Edison station service, gives a total of 613,991, or, with isolated plant service, 708,458 16 candle-power equivalent.

Bowling Green Storage Battery Annex.—The generating plant in that portion of the Produce Exchange Building rented from the Produce Exchange as an annex station, was entirely removed in the month of April, and in its place provision was made for a storage battery Annex in the new Bowling Green Building, so near as to permit the utilization, by running feeders across Broadway, of the existing distributing center adjoining the Produce Exchange. By arrangement with the proprietors of the Bowling Green Building, space was obtained in the sub-basement of that building for the installation of a storage battery, supplied by the Electric Storage Battery Company, of Philadelphia, of a capacity of 8,000 ampere hours at a ten-hour discharge rate or 4,000 amperes at 125 volts for one hour. By careful handling of the charging of the battery, it has been practicable to keep the large units at the Duane Street Station operating at practically full load and with most economical results, during the hours while these are in service.

An Annex Station, installed on premises temporary leased at 72d street and 5th avenue, is supplied by the Manhattan Company from its main station at the foot of 80th street, with high tension two-phase alternating current, operating a 240 k. w. two-phase motor at 2,000 volts. This drives two 100 k. w. 135 volt Edison direct current dynamos, furnishing low tension current which reinforces the supply in the upper district, pending the further development of the 53d Street Station system.

"Operating Results.—The highest load of the entire system taken together was on December 15, a maximum of 79,360 amperes. The best daily average of the system was on December 22, 28,926 amperes..

The total current generated in the year was in the downtown district, 68,738,565 ampere hours, and in the uptown district 84,581,417 ampere hours; in both districts a total of 153,319.982 ampere hours.

The modern equipment of 12th Street Station, including the storage battery, the turbo-generator and the water cooling tower, has shown most interesting and on the whole satisfactory results, although there have been some drawbacks in the handling of all these new classes of appliances, as is usually the case in pioneer work. By help of the storage battery at 12th Street, the generating plant of the entire system, with the exception of that of the 26th Street Station, was shut down on several occasions over night or over Sundays, for the purpose of testing the practicability of running the entire system from one generating plant during the hours of minimum load. The results show that this is quite practicable, and with the aid of the new storage battery in the Bowling Green Annex, it is probable that considerable improvements in economy will be developed in this way during the coming year.

Underground Installation.—The mileage of the underground street system December 31, 1895, was, on the 3-wire system, 68.76 miles of feeders and 133.92 miles of mains, a total of 202.68 miles of the 3-wire system; and on the 2-wire system, 0.24 mile of mains. The total mileage December 31, 1895, including 1.41 miles of cable feeders contiguous to the stations, was 202.92 miles of mains and feeders. The system also included December 31, 1895, 1,160 junction boxes at intersections.

The net increase of the system, in both districts, is 6.41 miles, bringing the grand total December 31, 1896, to 209.33 miles. The increase in junction boxes has been 48, making a total of 1,208. The number of service connections added during the year was (net) 317 in the downtown district, and 402 in the uptown district; in both 719.

Inspection Department.—The Inspection Department has been most successful in its work of the year, combining as hitherto the functions of the general agency and of general inspection, increasing the business of the company and at the same time improving the standard of insulation and of installation generally. During the year 230 contractors have reported installations, involving 2,840 reports. Of these 13 have reported installations reaching over 1,000.

Of electric motors, in which the exceptional development of 1895 has continued throughout 1896, 47 types have been installed on the system, numbering 1,319 motors, averaging 3.47 h. p. each and aggregating 4,290 h. p. The use of electric elevators continues to increase.

Meter Bureau.—The Meter Bureau, under the general charge of the Controller, has been very efficient during the year; it had under its care on December 31, 1896, 8,532 meters in customers' premises, of which the great number were Edison chemical meters. The most careful attention has been given to complaints from customers, as to amount of bills, etc., of which 1,359 were received during the year. In connection with these complaints, 86 errors were found, of which 63 were clerical and 23 technical, 14 of these last because of the freezing of meter bottles during extremely cold weather. The proportion of errors to bills rendered was but 1 in 1,107, or less than 1-10 of 1 per cent. The policy of offering to submit any disputed case to arbiters has been continued with satisfactory results.

---

* Exclusive of depreciation charges. † Not including outside earning.

Relations with Employés.—During the year past, the benefit-dividend paid to employés, has been placed on a more definite basis, so that the employés more directly reap the advantage of the bettered economies and increased revenues which they help to bring about. After deducting from the gross earnings a sum covering operating and general expenses, depreciation charges, and a minimum return on capital, a percentage on the balance equal to the rate of dividend paid to stockholders has been appropriated for the employés benefit fund. From this, there has been paid, in the week preceding Christmas, to all employés in continuous good standing in the service of the company, 4 per cent. on the annual salary or wages to those in the employ of the company for 10 years, 3 per cent. to those of 5 years' service, 2 per cent. to those of 3 years' service and 1 per cent. to those of one year's service. There are many evidences that this form of profit-sharing is thoroughly appreciated by the employés and it is believed that the effect is to obtain the most hearty co-operation of all in bettering the efficiency of the company's service.

Electrical Developments.—An electrical kitchen is now in practical operation at the company's building and can be seen on specified days in the week, on application by letter. The development of apparatus for this purpose is in a more promising state than ever before and its promoters are working in hearty co-operation with this company.

The development of the enclosed arc light, which requires trimming only once a week instead of once a day, is also proving a considerable advantage to this company and it furnishes a method of lighting large interior spaces which is most economical as well as most effective.

The net earnings of the company for the year were $960,156.94, including $126,582 earned by the high tension system (Manhattan Electric Light Co.) The company paid $322,100 interest on its bonds, and $476,220 in dividends (6 per cent.) on its stock of $7,938,000 issued. The report also treats of the city lighting done by the company, reference to which is made elsewhere in this issue. Reference is also made to the promotion of Mr. John W. Lieb, Jr., to the general managership of the company in recognition of his past services. Fitting reference is also made to the loss sustained by the death of Mr. Harry J. Smith, the late general operating superintendent of the company, in memory of whom a memorial is being prepared by the staff, to which the company is also contributing.

THE STOCK MARKET

GENERAL QUIETNESS.

THE condition of the industrial and stock markets during the past week has been dull, but curiously uneven. There has been a break, for example, in price of rails, but leather has gone up. The railway share market and bonds have been firm, but industrials, in spite of steadily improving trade, have weakened a bit under pressure of the bears. That the general state of affairs is better, outside the unsettled politics of hell's kitchen down in southeastern Europe, is shown by the list of some thirty signs of incontestable improvement enumerated by a financial authority.

For a great property, American Bell Telephone is always singularly inactive, but it was seldom more so than last week when only 248 shares were sold, making an advance of half a point up to 217½. From Boston, however, come reports of a movement contemplated by a group of local holders of General Electric preferred stock to take the matter of their unpaid dividends into court. They may set up the claim, on the recommendation of New York attorneys, that the pending dividend default gives them a lien on current earnings from the date on which they demand and fail to receive payment. It may also be set up that official representations upon which the preferred stock was sold made a contract additional to the stated terms in the issued certificates. During the week, in New York, 10,231 shares of General Electric were sold, declining from 35¾ to 34⅜.

In telegraph stocks there was little activity and the same is generally true of local lighting and street railway securities all over the country. The weather and the holidays account perhaps for much of the apathy. Of Western Union only 5,528 shares were sold, declining slightly to 82⅜.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED FEBRUARY 9, 1897.

Batteries, Primary:—

GALVANIC BATTERY. H. J. Brewer, New York, 576,720. Filed May 18, 1894.

Comprises a covered cell, a central carbon surrounded by loose carbon contained in a pervious sack, and a zinc element.

BATTERY. F. B. Badt, Chicago, Ill., 576,936. Filed Sept. 7, 1894.

The jar is provided with a circular channel at the upper edge, and a circular projection upon the cover is adapted to rest in the channel, a liquid insulating material in the channel, permitting the escape of gas.

Connectors, Conduits and Insulators:—

OUTLET BOX. J. J. J. DeRycke, New York, 576,810. Filed May 2, 1896.

A thin cast-iron box divided along the midthickness and having a series of discs arranged on the side walls and bottom capable of being broken away by light blows of a hammer, leaving a clean circular opening where required to receive the open end of the conduit.

Electro-Metallurgy:—

APPARATUS FOR ELECTRICALLY HEATING METAL. G. D. Burton, Boston, Mass., 576,545. Filed March 30, 1895.

Apparatus for heating metal to a forging, welding or fusing heat by means of an electric arc sprung between the metal and an electrolytic bath.

Lamps and Appertenances:—

ELECTRIC ARC LAMP. H. Baurlin, Aarburg, Switzerland, 576,802. Filed May 11, 1896.

Feed mechanism for shunt regulated arc lamps.

Miscellaneous:—

TROLLEY SYSTEM. W. F. Caffrey, Reno, Nev., 576,721. Filed April 2, 1896.

Adapted for horseless carriages.

ELECTRIC HEATING APPARATUS. A. Robertson, Taunton, Mass., 576,766. Filed April 5, 1895.

Comprises a casing perforated at its bottom and along its upper front portion; a plurality of heating bars each made up of a wide thin bar of metal, an insulating covering and a heating coil.

Railways and Appliances:—

ELECTRIC LOCOMOTIVE AND RAILWAY SYSTEM THEREFOR. M. Schalscha, Hoboken, N. J., 576,622. Filed Feb. 20. 1896.

Automatically controlled car adapted for conveying material such as coal from a vessel to place of storage.

STATION INDICATOR. J. D. Keen and J. J. Roberts, Louisville, Ky., 576,854. Filed Sept. 24, 1896.

By closing the circuit the motor is released and moves the ribbon to bring into view the name of the next station.

ELECTRIC LIGHTING FOR VEHICLES. J. A. Ageron, Paris France, 576,933. Filed Aug. 2, 1895.

A generator adapted to be operated by the rotation of the wheels.

Regulation:—

ELECTRICAL REGULATING DEVICE. J. F. Kelly, Pittsfield. Mass., 576,732. Filed July 24, 1893.

Comprises an alternating current generator used as a source of electrical supply, one or more feeders for conveying the current from the same, and a regulator for each feeder, consisting of an induction motor connected with the feeder and driven at a speed above that of synchronism.

Switches, Cut-Outs, Etc.

ELECTRIC SWITCH. M. Schalscha, Hoboken, N. J., 576,621. Filed Feb. 20, 1896.

Automatic motor switch.

VENTILATED FUSE PLUG FOR ELECTRIC CIRCUITS. H. C. Wirt, Schenectady, N. Y., 576,710. Filed Nov. 20, 1896.

Details of construction.

Telephones:—

TELEPHONE TRANSMITTER. M. E. and E. C. Clark, Minneapolis, Minn., 576,551. Filed Sept. 23, 1895.

Comprises a diaphragm of insulating material, with a multiple contact device secured directly upon it, and provided with a large number of contact points, a disc to engage the contact points and a binding piece of material similar to that of which the diaphragm is formed, and whereby the disc is secured upon the diaphragm and multiple contact device.

TELEPHONE SYSTEM. A. S. Hibbard, Chicago, Ill., 576,577. Filed May 4, 1896.

Coin controlled telephone system.

TELEPHONE APPARATUS. C. E. Buell, North Plainfield, N. J., 576,804. Filed April 24, 1895.

A subscriber's station apparatus that comprises a telephone apparatus in a derived branch, a calling instrument in the main line, a local circuit that includes the primary of an induction apparatus, and connections from the derived branch local circuit to the armature of the calling instrument.

TELEPHONE TRANSMITTER. J. F. Gilliland, Adrian, Mich., 576,813. Filed Dec. 21, 1895.

Comprises saucer-shaped electrodes provided with a groove about the facing edges, a resilient non-conducting ring located in the grooves, granular conducting material confined between the electrodes, and opposite axial bearings for supporting the united electrodes.

LEGAL NOTES

STATE TAXES OF TELEGRAPH COMPANIES SUSTAINED.

The United States Supreme Court has sustained the Indiana law taxing telegraph companies, which was brought up for review by appeal from the judgment of the Indiana State Supreme Court. From this decision Justices Harlan and White dissented. One reason for their dissent was stated by Justice Harlan. The law of Indiana taxing railroad companies provides a penalty of 16 per cent. for delinquency; in the case of telegraph companies the penalty for delinquency is increased to 50 per cent. This, Justice Harlan said, was a denial of equal protection of the law guaranteed by the Federal Constitution.

SWITCH PATENT CASE DECIDED IN FAVOR OF THE WESTERN TEL. CONS. CO.

Judge Showalter, in the United States Circuit Court, at Chicago, has handed down a decision in the case of the Western Electric Company, representing the Bell Telephone Company, against the Western Telephone Construction Company, finding in favor of the defendants. Suit was brought against the Western Telephone Construction Company for an alleged infringement on the Western telephone switch, a device doing away with the call bell. Judge Showalter held that the switch was no novelty, the same idea being embodied in the prior Watson and Roosevelt patents. The details of the case have already appeared in these columns.

LETTERS TO THE EDITOR

TO PREVENT TAMPERING WITH METERS.

We have found places where the electric light meters have been tampered with and in other places current has been stolen and connections made with feed wires without the knowledge of the Light Department. In order to successfully prosecute such cases we propose to have an act passed in the State Legislature which will give the courts power to punish the theft or undue interference with meters and electric light wires.

BOARD OF PUBLIC WORKS.
By David Rydstrom.

Tacoma, Wash., Feb. 2, 1897.

PERSONAL

CAPT. SAMUEL TROTT, of the cable steamer "Minia," was a visitor in New York last week, where his many friends were glad to see him in restored health and to congratulate him on his recent saving of lives at sea.

MR. JOHN CAMPBELL, who was until recently the local superintendent and manager of the Postal Telegraph Company at Pittsburg, has accepted the position of manager of the Pittsburg district of the independent Home Telephone Company which proposes to carry on a vigorous opposition. Mr. Campbell is a man of marked energy and ability.

MR. ALBERT VICKERS has been made general manager of the Buffalo, North Main street and Tonawanda Electric Railroad. He announces a number of improvements to be constructed in the spring.

MR. F. H. MICHALES has been appointed city electrician of Peoria, Ill. He is an experienced man and graduates from the telegraph service.

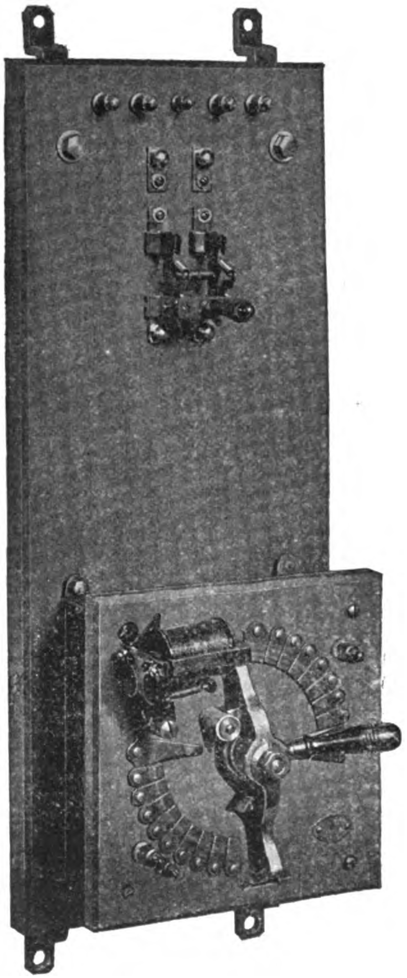
MR. WILLARD E. CASE is to lecture before the New York Electrical Society at Columbia College, on Feb. 24, his subject being "Electricity from Carbon Without Heat." Mr. Case has long been an experimenter in this field, and has a great deal of interesting and valuable data, which will be appreciated by electrical engineers and students in all lines. Mr. Case has made for the occasion a variety of apparatus to illustrate types and principles.

MR. WM. TAYLOR, the well-known electrical manufacturers' agent at 203 Broadway, has won the prize of a trip around the world given by the "Evening Telegram," for the nearest guess to Mr. McKinley's plurality in the popular vote. He made nineteen coupon guesses and one of them was 597,397, or within 8 of the actual 597,389. The next 49 nearest guessers will be given a free trip to Washington for the inauguration exercises.

TRADE NOTES & NOVELTIES

NEW G. E. PANEL BOARD.

THE importance of economy in the space occupied by operating appliances and the necessity of making as few wiring connections as possible in small direct current motor installations, has assumed the shape of a brisk demand, which the General Electric Company meets by a series of small switchboard panels designed for motors of the usual voltages and capacities ranging from ½ horse-power up to 16 horse-power. The equipment of each panel consists of a main switch, fuse-holder and motor starting rheostat with automatic release switch, the connections themselves being embodied in the panel. For motors up to 300 volts, open fuses are used, while for voltages higher than 300 volts, magnetic fuse holders are mounted on the panels.



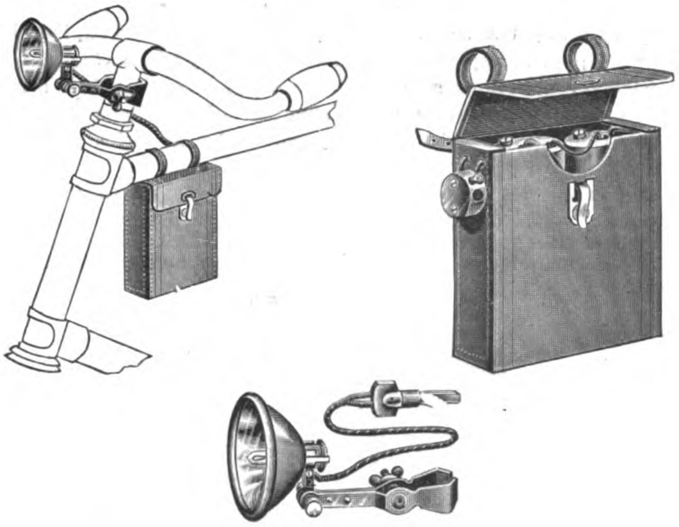
New G. E. Panel Board.

The only connections necessary when installing the motor are those from the motor and mains to the five binding posts at the top of the panel. The panels are of plain slate, enameled slate or blue marble, the enameled slate being considered superior on account of its wearing qualities and finished appearance. Each panel is self contained and is provided with iron supports for adjustment to the wall or to a post adjacent to the motor.

THE "LUMINO" ELECTRIC BICYCLE LIGHT.

THE Cycle Exhibition just concluded in New York, exemplified the wide application of electricity in this as in almost every other field of daily work and diversion. Bicycle riders have from the beginning been longing for a light which will relieve them from the annoyances of the oil lamp, and also afford a more powerful and reliable illumination. To meet their wants, the Leecol Storage Battery Company, of 76-82 Jackson Boulevard, Chicago, Ill., have got up a neat little storage battery and electric lamp outfit, which they have named the "Lumino," and which attracted much attention at the Show. The outfit consists of a two-cell storage battery enclosed in a leather case, hung from the top bar of the diamond frame, or from the handle bar of the drop frame machine, as shown in Figs. 1 and 2.

The lamp is enclosed in a small, heavily silver plated reflector, Fig. 3, which is mounted on a swivel support, and connected with the battery by short flexible cords.



Figs. 1, 2 and 3.—The Lumino-Electric Bicycle Lamp.

The miniature incandescent lamp is mounted on a cartridge shaped base, so that it can be pushed into the back of the reflector.

The battery has capacity sufficient to afford a light for eight hours, but larger batteries can be arranged for longer lighting when desired. The batteries are accompanied by a resistance in the shape of an incandescent lamp, by means of which they can be charged directly from an incandescent light circuit.

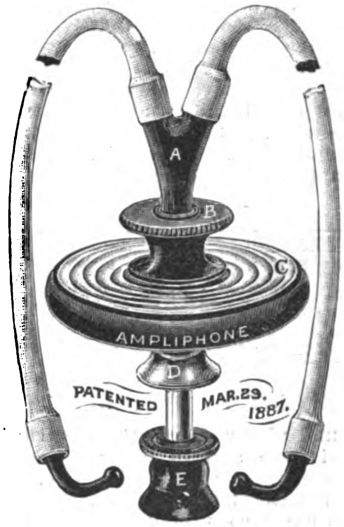
The whole outfit is gotten up in a workmanlike manner and ought to take well among the wheeling fraternity. The storage battery is of extremely simple form, and appears to have remarkable powers of endurance and stability.

P. & B. INSULATING COMPOUNDS.

Mr. Frank S. De Ronde, the general sales agent of the Standard Paint Company, 81—83 John street, New York City, says: "The demand for our well known P. & B. insulating compound is constantly increasing. There are some manufacturers who are pushing their goods to the front as the "best" with nothing to prove their bold assertions but their own claims. It takes but a short time to demonstrate the worthlessness of these inferior materials. In the many years that P. & B. has been before the electrical public it has proven itself to be all and more than the manufacturers claim for it. In special places where an insulating and preservative compound is needed, people cannot take the chances of using an inferior material when they can get P. & B. at a reasonable price. Our goods are handled by dealers everywhere. If for any reason electricians cannot get P. & B. from their dealer, we invite correspondence direct. We are willing to send good sized samples of our insulating compound, preservative paints, armature varnish, and insulating tape to any electrician who will ask for them. We will not send little samples by mail, but good sized samples by express prepaid, sufficient for practical trial. Even our preservative paint, which is sold at a price competing with the cheap, inferior, so-called insulating paints, will give much better satisfaction than any of these in the market. Years of use prove more than a few hours or a few days' trial. Our references are electricians and electrical manufacturers the world over."

THE AMPLIPHONE.

THIS instrument, which is now attracting wide attention among the medical profession on account of its peculiar adaptability to their uses in the magnifying of sounds pertaining to diseased organs, etc., is the invention of A. A. Knudson, well known as an inventor in electrical and acoustic apparatus. Although this invention was patented ten years ago, and first intended for use in telegraphy, by providing a method by which only the operator could take a message from a relay adjusted low, it has not as yet come into use for that purpose, although successfully tried on the lines of one of the large companies. The instrument itself as now designed is very simple in construction. By referring to the cut a good idea of its construction and appearance may be obtained. It will be seen that the magnified sound of the ampliphone is conducted to the ears of the person using it, through rubber tubes which terminate in hard rubber ear bulbs similar to those of the phonograph. These rubber tubes branch out from the Y-piece of the instrument, A, which is inserted in the socket which connects with the air chamber of the instrument. B is the hard rubber knob which is screwed to a stud which projects through the diaphragm, C, and serves as a handle to manipulate the instrument. C is the upper diaphragm, the lower one not being shown, but is an exact counterpart; both of these diaphragms are pressed out of very thin aluminum, the exact thickness being 12/1000 of an inch, and are shaped with circular corrugations. These diaphragms are slipped over the edges of a brass rim having grooves into which the edges of the diaphragms are depressed and are thereby firmly secured. A polished rubber ring is then driven over the whole which completes its finished appearance. D is a metal bell-shaped terminal, which is placed against the object or person whence the sound emanates. E is a hard rubber bell screwed to the end of the small metal tube, which is also screwed when in use into the metal bell, D, attached to the instrument.



Knudson Ampliphone.

All of the metal parts, including diaphragms, are nickel-plated, and highly polished, making a handsome and attractive looking instrument. The whole appliance weighs but two and a half ounces and can easily be carried in the pocket. A morocco case lined with satin is furnished in which it is kept together with the tubes when not in use. Mr. Knudson informs us that he expects to make other applications of this invention either in its present or modified form, and we shall look with interest for new developments in other fields where it may prove as useful and successful as it is now in the medical.

The sole manufacturers of this appliance are Fred. Haslam & Company, 83 Pulaski street, Brooklyn, N. Y.

HELIOS.

THE new edition of the Heine Safety Boiler Company's catalogue "Helios" is, if anything, even more useful than its predecessors. There is scarcely a problem in the generation or utilization of steam that is not treated of and reduced to data in "Helios," and as a result the volume is of the greatest possible value to every steam user. We find among its pages valuable tables on the properties of steam, the heating value of the principal American coals, analyses of water for boilers, chimney construction, condensation in pipes,—in fact everything that the owner or operator of a boiler ought to know.

Not the least interesting part of the work is the series of views of buildings in which the Heine safety boilers have been installed. They embrace the whole country and form a striking testimonial of the merits of the company's product.

THE NEW YORK TELEGRAPH AND TELEPHONE CONSTRUCTION CO.

Mr. Paul Minnis, chief engineer of the New York Telegraph and Telephone Construction Company, and New York representative of the Best Telephone Manufacturing Company, of Baltimore, left on the 4th inst. for a Southern business trip of about two months. Mr. Minnis is interested in the Southern Home Telephone Company, a parent organization lately organized to operate in the States of North and South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Arkansas and Tennessee. This company is being promoted under the auspices of the Southern Telephone Security Syndicate, a promoting and brokerage company organized for the purpose, and it is in the capacity of trustee of this latter organization that Mr. Minnis goes South.

While in the South he will decide upon the location of a telephone factory to handle the overflow from the Best Telephone Manufacturing Company, of Baltimore, that company having found the demands upon it by its affiliated companies so far in excess of its possible present output, that it is forced to establish subsidiary factories in order to take care of its increasing business. Inducements have been offered by three available Southern cities, but Mr. Minnis states that it will probably be two or three weeks before the preference is given to any one of them.

ADVERTISERS' HINTS

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., publish a list of recent sales of dynamos, motors and engines. It is a good one and sets forth quite clearly the growing popularity of their apparatus.

THE GENERAL ELECTRIC COMPANY state that there are now over 300,000 of their arc lamps in service.

THE NATIONAL TUBE WORKS COMPANY claim to be the largest makers of all sizes and kinds of special wrought mild steel and best wrought iron tubular goods in the world, controlling the manufacture of wrought tubular goods made of a high class of mild steel from the ore to the finished product.

THE C & C ELECTRIC COMPANY include everything in their manufacture of electric machinery for the complete equipment of central stations and isolated plants.

THE AMERICAN ELECTRIC METER COMPANY, Philadelphia, have removed their offices from the Betz Building to Ninth street and Montgomery avenue.

THE CROCKER-WHEELER ELECTRIC COMPANY draw special attention to the design and finish of their belted and direct connected dynamos and motors.

THE SHELBY ELECTRIC COMPANY, Shelby, O., claim their incandescent lamps are 20 per cent. more economical and 30 per cent. longer lived than any other.

CHAS. WIRT, Philadelphia, offers a very convincing testimonial regarding the merits of his dynamo brushes under constant service.

McLEOD, WARD & CO., 27 Thames street, New York, say that none of the imitators have been able to equal them in their desk light—the "Kinsman."

THE AMERICAN STEEL ROOFING COMPANY claim to have a roofing which is all that is needed: fireproof, durable, neat and economical.

CAHALL SALES DEPARTMENT advertise a list of companies using their boilers.

TRIUMPH ELECTRIC COMPANY, Cincinnati, O., make a specialty of direct current municipal lighting plants.

DONLEY & BUNCE, Monadnock Building(Chicago, are exclusive agents for the Cloos junction box.

ABENDROTH & ROOT MANUFACTURING COMPANY, New York, point out many advantages their boilers possess.

BIBBER-WHITE COMPANY, 49 Federal street, Boston, Mass., are selling the "Boston" transformer.

THE WESTERN ELECTRIC COMPANY have issued a very complete price list on Boudreaux dynamo brushes, Perfection dynamo brushes, Wirt dynamo brushes and carbon brushes. All central station men should have one of these price lists on file.

NEW YORK NOTES.

SPRAGUE ELEVATORS.—A large 20-story building is being put up for R. G. Dun, of the Dun Commercial Agency, at Broadway and Reade street, and a contract has been awarded to the Sprague Electric Elevator Company for six multiple sheave electric passenger elevators, and one freight machine. These elevators are to have an average speed of 450 feet a minute, and will be installed with all the most modern and approved appliances. The Sprague Company continues to capture a great deal of the best work not only in New York, but all over the country.

KENT'S LUBRICATING COMPOUND.—This compound is constantly increasing in popularity. Owing to its peculiar composition it adheres to the bearing surface, where it is needed, instead of flowing away from it. Every particle of it is a lubricant, but the mixture is so happily chosen that they blend perfectly and form a homogenous and stable compound. Among the hundreds of users of Kent's compound we may mention the following recent ones: The New York Herald, Consolidated Gas Company, Jackson Architectural Iron Works, L. H. Mace & Co., Travers Brothers, Bronx Company, F. E. James, branch of National Wall Paper Company; J. L. Mott Iron Works, Methodist Book Concern, Quintard Iron Works, J. E. Linde Paper Company, Potter Printing Press Company, Baumgarten & Co., Messrs. William M. Crane & Co., Columbia Typewriter Company, Messrs. Joseph Wild & Co., the P. Lorillard Company, Principio Forge Company, Siegel-Cooper Company, N. Y. Quinine Chemical Works, Messrs. Otis Brothers, Johnston Building, Man. Company and Merchants' National Bank Building, Messrs. James Pyle & Son, Metropolitan Street Railway Company, National Saw Company, De La Vergne Refrigerating Machine Company, Interior Conduit and Insulation Company, Louis Bossert, Ferguson Brothers, Edwards & Co., Judge Building, George Fox's Sons, Central Cooperage Company, Hudson Steam Laundry, Harper Brothers, Standard Bleachery, Robert Gair, N. Y. Biscuit Company, Walden Knife Company, Tyler Tube and Pipe Company, Urban & Co., Messrs. R. H. Wolff & Co., Presbyterian Building, American Surety Building, Mr. John T. Williams (builder), the Union Pearl Works, Messrs. Curtis & Blaisdell, Messrs. Joshua Oldham & Sons. The Kent's lubricating compound is sold by the New York and New Jersey Lubricant Company, 30 Cortlandt street, New York.

KINSMAN AND KNUDSON is the name of the new firm just established by F. E. Kinsman and A. A. Knudson, both of whom are widely known as engineers and inventors. They have opened offices in the Manhattan Life Building, 66 Broadway, as consulting and supervising electrical engineers, and will make expert examination of new inventions and new enterprises.

MR. H. H. HUMPHREY, of the firm of Bryan & Humprey, consulting mechanical and electrical engineers, St. Louis, is a visitor East, and was in New York City last week.

HENRY R. WORTHINGTON has just been awarded a contract by the City of Chicago, covering six vertical triple expansion direct-acting high duty pumping engines, each of twenty million gallons daily capacity. This contract amounts to $437,600, and is the largest contract for water works pumping machinery ever placed in this country. The above six engines each have a daily pumping capacity of twenty million gallons against a head of 150 feet, and will be supplied with steam at a pressure of 140 lbs. to the square inch. The engines will each be of 530 horse-power. This company is also building three vertical triple expansion direct-acting high duty pumping engines for the city of Brooklyn, N. Y., under a contract amounting to $385,000. These engines each have a daily capacity of twenty million gallons to be delivered against a head of 168 feet, and the steam will be supplied at a pressure of 135 lbs. to the square inch, each engine being of 600 horse-power.

POLES BY THE THOUSAND.—The largest order ever placed for manufactured tapering yellow pine poles, numbering 3,000, ranging in length from 25 to 35 feet, has just been awarded to S. C. Strock, of 50 Broadway, New York, by the American Telephone and Telegraph Company, for use on its lines. Mr. Strock is a man well known to the electrical field on account of his former connection with the Thomson-Houston and General Electric Companies.

MR. W. POMEROY, of the Bossert Electrical Construction Company, Utica, N. Y., delivered a lecture there last week before the Railroad Y. M. C. A., on "Electricity: Its Past, Present and Future."

MR. CHAS. B. MARTIN has been appointed electrical engineer of the Brooklyn Bridge at a salary of $2,500.

THE IRON CLAD RHEOSTAT COMPANY, of Westfield, N. J., have just issued a new broadsheet price list of their new theatre dimmers. They cover the ground thoroughly in a great variety of styles. There are over 2,500 of these dimmers in daily use, varying from 1 to 1,440 lights capacity. Many of these have the company's special interlocking device. The Iron Clad Company make a specialty of theatre dimmers and have a long list of patrons, attesting the superior character of their product. Cuts, sizes, prices, etc., are carefully given in the sheet, which the company will be glad to forward to any address. It will also be glad to furnish data or respond to inquiries in regard to new work in this line.

F. P. JONES, of 126 Franklin street, Buffalo, informs us that he has sold out his interest in the F. P. Jones & Co., a corporation which, together with its predecessor of similar name, has been doing business in the city for ten years past. He has opened up in the same line, and wants to receive manufacturers' prices, catalogues, etc.

WESTERN NOTES

THE ELECTRIC APPLIANCE COMPANY are at present distributing two very neat circulars of some of their specialties and staple goods, one circular being devoted to porcelain tubes and insulators, and the other to sparkless and Boudreaux dynamo brushes. In connection with the circulars, the Electric Appliance Company are quoting a revised discount on these goods, low enough to warrant the assurance that considerable business will result. They will be pleased to send circulars and quote discounts where they have not already been received.

CENTRAL ELECTRIC COMPANY announce that they are having quite a demand for their new type of station switchboards. These are finished in various designs, and are shipped assembled ready for erection if desired.

THE METROPOLITAN ELECTRIC COMPANY of Chicago, have been given the Western Agency for the Ham Sand Box. This is a new sand box for distributing sand and gravel on the rails, while the cars are in motion. It is used on railroad trains as well as street cars, and the box is making a good deal of stir in the railroad world. The great trouble with sand boxes is that they operate with a valve, and this valve gets clogged up with the sand and the gravel passing through it. This new sand box, however, gets away with this difficulty entirely by omitting the valve, and substituting a simple device for equally distributing the material to be used on the tracks, whether it be sand, gravel or salt. The company are putting them out on trial, not to be paid for unless satisfactory, and are making a very low price on this sand box.

NEW ENGLAND NOTES

FRENCH COFFEE POTS.—This week the American Electric Heating Corporation, of Boston, announce the addition of a French coffee pot to their line of domestic utensils. In the past, such articles have been made with the electric heater permanently attached to the device, thereby rendering it nécessary to have a number of complete outfits to do a limited amount of work. The coffee pot above referred to is made to fit a 4½-inch disc heater and is of ample size for the wants of four people. It is made of block tin and so designed that all of the heat generated in the stove is used. Two of the $4 stoves, with a stew pan and coffee pot, will enable a family to cook a breakfast of coffee, toast and eggs in the time required to build a fire and get the ordinary stove ready.

PHILADELPHIA NOTES

WIRT DYNAMO BRUSHES.—Mr. Chas. Wirt, 1028 Filbert street, Philadelphia, has received the following letter from John Weyker, chief engineer, Kinsley's Restaurant, Chicago: "The Wirt dynamo brushes which you furnished for our Edison dynamo four years ago, have been in use seven days a week and about fifteen hours per day ever since. The brushes are still good for some time to come and the wear on the commutator is imperceptible."

SOUTHERN NOTES.

BALL ENGINES.—The Wilmington Gas Light Company, Wilmington, N. C., is installing a 350 horse power horizontal cross compound engine built for them by the Ball Engine Company, Erie, Pa. A 60-horse-power engine direct connected to 25 horse-power General Electric dynamo, has been recently placed in the Church Home and Infirmary of Baltimore, Md., by Crook, Horner & Co., representing the Ball Engine Company.

The Electrical Engineer.

Vol. XXIII. FEBRUARY 24, 1897. No. 460.

MISCELLANEOUS

DETAILS OF CARBORUNDUM FURNACE AND ITS OPERATION.

While a good deal has been written about the manufacture of carborundum, very little has been said, so far, about the electrical part of the work. The following details of the operation of a carborundum furnace may, therefore, be of interest to electrical engineers.

Although from a general description of the manufacture of carborundum it may seem a comparatively simple process, yet this is really not the case, for it is only by long experience and an immense number of experiments that the present high efficiency of the process has been attained. At the old works of the Carborundum Company, in Monongahela, Pa., 134 horsepower was employed, and it was by the most careful study of the results obtained there, that it was possible to at once operate in an efficient manner the Niagara Falls furnaces, using, as they do, nearly eight times as much power.

Obviously one of the most important considerations is the construction of the furnaces, so it will not be out of place to consider that subject briefly. The furnaces are built of brick in the form of an oblong box, Fig. 1, having the following dimensions: Length, 16 feet; width, 6 feet; depth, 5 feet. An iron frame about 2 feet square, is built into either end of the furnace, and encloses 60 carbon rods 30 inches long and 3 inches in diameter. From a hole bored in the centre of the end of each carbon a piece of ⅝-inch copper wire projects and passes tightly through a corresponding hole in a stout bronze plate bolted to the frame and having four projections to which are bolted the cables conveying the current to the furnace.

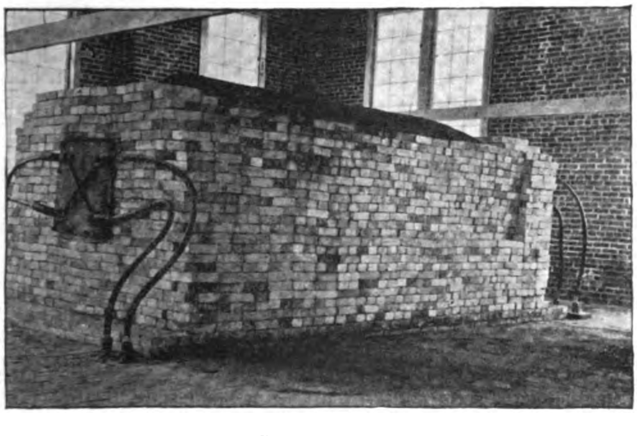

Fig. 1.—A Carborundum Furnace.

Unlike the ends of the furnace the sides are merely temporary structures that are taken down after every run. When the sides of the furnace have been built up, pieces of sheet iron are placed in such a way as to prevent the mixture or charge for the furnace from coming in contact with the inner ends of the carbon rods.

The mixture, consisting of sand, coke, sawdust and salt, is now thrown into the furnace until it is rather more than half full, and in this a semicircular trench, extending from one piece of sheet iron to the other, and having a diameter of 21 inches, is formed. Into this trench is introduced the "core" which consists of grains of coke that have passed through a screen with four meshes to the inch. The weight of the core is adjusted so that when finished it forms a cylinder of coke grains 21 inches in diameter. The connection between the core and the terminals of the furnace is made by packing finely ground coke in the spaces between the pieces of sheet iron and the ends of the carbons, and then withdrawing the former. This having been done, more mixture is thrown on the furnace and heaped up to a height of about eight feet, after which the furnace is ready for operation.

The current as supplied from the power house is at 2,180 volts and is transformed at the carborundum works to one of 166 volts. In operating a furnace it is necessary to have some means of varying the e. m. f. between the terminals, for at starting, the resistance of the core is comparatively high, but is greatly reduced when the furnace becomes hot. In the Monongahela works the e. m. f. was varied by altering the field current of the dynamo, further variation being obtained by throwing the transformers, which were arranged in two batteries, into series or parallel as the case might be.

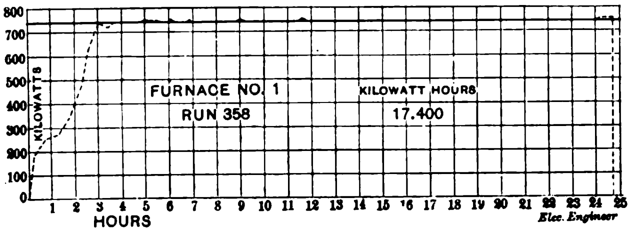

Fig. 2.

The result of his long experience with this arrangement demonstrated to Mr. Acheson the importance of having some really accurate method of regulation, a method that would be continuous. Accordingly when the plans for the Niagara Falls works were under consideration there was much discussion on this subject. Some of the engineers were in favor of constructing the transformer in such a way that, by means of switches, coils of the primary could be thrown in or out, thus varying the voltage of the secondary circuit, for they considered that Mr. Acheson's idea of using some kind of induction regulator was impracticable. Professor Forbes, however, was in favor of the induction regulator and the plans for an instrument of this sort, submitted by the General Electric Company, were finally decided on. By means of the induction regulator the e. m. f. between the terminals of the furnace can be varied between a maximum of about 230 and a minimum of 80 volts. The remarkable success attending the use of this instrument is shown by the power curves of the furnaces.

When the furnace is ready for operation, the cables are bolted to the terminal plates, the primary circuit closed in the transformer room by means of a water rheostat, and the regulator "run up" so as to raise the voltage. There are two kinds of core used in the furnaces, known as "new" and "old" core, respectively. The former consists of coke, as it comes directly from the screens, while the latter has already been used in a furnace. It is customary to give an e. m. f. of 175 volts to the current supplied to a furnace containing new core; but with old core a current of 140 volts is used. The reason for this is that the core which has already been used in a furnace has been heated to such a high temperature that all impurities have been driven off and nothing but pure carbon, having a much lower resistance than coke, is left.

While the furnace is running, readings of the voltmeter and ammeter on the secondary circuit are taken every fifteen minutes, and from these the kilowatts are calculated and the power curve is plotted. Two typical examples of these power curves are shown in Figs. 2 and 3. Run 358 shows the curve of a "new" core furnace, while Run 387 is an "old" core.

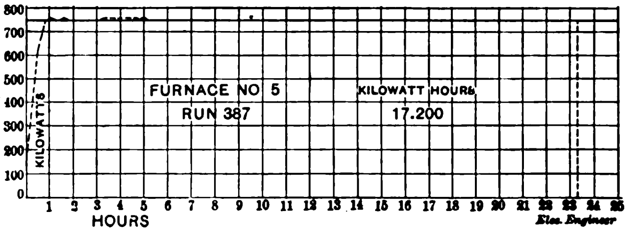

Fig. 3.

It will be observed that the former takes three hours to come up to the full load of 746 kilowatts indicated by the horizontal line, while the latter reaches the full load in forty-five minutes. By comparing Run 358 with Run 702, a Monongahela "new" core furnace, Fig. 4, it will be seen how much better the regulating scheme in Niagara Falls is, and there can be no doubt that the high efficiency of the Niagara Falls furnaces is largely due to this.

The portion of the conductance curve of Run 429, Fig. 5, shows the remarkable effect that a comparatively brief stoppage of the current has on the resistance of the core. When the furnace had been running for 19.3 hours, it was necessary to break the circuit in the transformer room and remain shut down for 42 minutes. On starting up again the resistance of the core had increased so much that it was necessary to raise the voltage in order to bring the load up to 746 kilowatts, and even then it was nearly two hours and a half before the resistance of the core was reduced to its value at the time of shutting down.

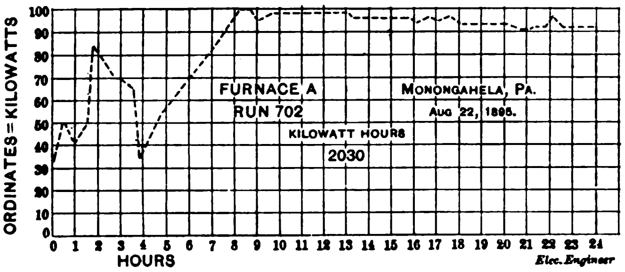

FIG. 4.

In the case of Run 398, Fig. 6, a core altogether too small in diameter was used. The result of this is to produce a very high temperature in the core and consequently a very rapid formation and decomposition of carborundum accompanied by the formation of large quantities of carbon monoxide and other gases. The result is that the gases cannot escape with sufficient rapidity through the mixture and hence form vents through which they rush out with considerable violence forming miniature volcanoes. These phenomena are usually attended with considerable disturbances of the whole upper portion of the furnace, which cause displacements of the core and consequently very rapid changes in its resistance. This is illustrated very clearly by the parts of the conductance curve of Run 398 shown here. When the gases begin to escape through vent holes in this manner, it is usually necessary to shut down the furnace, and cut out the vent hole.

It is not the purpose of this article to enter into all the minute details of the operation of carborundum furnaces; but rather to show the main points of interest in the application of electrical engineering to this new branch of electro-metallurgical work. The electric lighting engineer appreciates the extreme importance of very small variations of current in the efficiency of his lights when they have reached a point near their full candle-power, and that to have his lamp efficient they must be adjusted with the greatest accuracy to the conditions under which they will be used. The operation of a carborundum furnace presents an exactly parallel case, and it is for this reason that the behavior of every furnace is studied with such care by means of curves, examples of which are shown above.

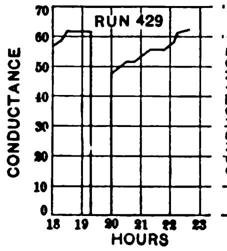

FIG. 5.

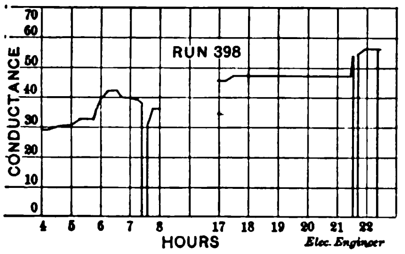

FIG. 6.

PLAYING WITH HORRORS.—One of the "new journalists" tried recently to get up a little scheme for putting Maria Barberi, who was acquitted for killing her brutal lover, into the electrical execution chair and giving her a little dose of current, to see the effect and describe it.

GASEOUS FUEL AS A MEANS OF CHEAPENING ELECTRICITY.[1]

BY NELSON W. PERRY, E. M.

THERE is certainly something wrong in the existing state of affairs, which the electrical engineer must correct. The most significant feature of the situation is that notwithstanding the fact that gas is distributed over very much greater distances than low tension currents are, the consumer can buy it so cheaply that he can produce electric light more cheaply by burning it in a gas engine even after incurring the losses in conversion in the engine and dynamo, than he can buy it from the electric company. If this be true in large cities like Chicago, New York, Philadelphia, Brooklyn and Boston, and it cannot be gainsaid, what must be the condition of light and power plants in smaller and less favorably situated cities.

Many managers now find themselves confronted with the question, Is it possible for me to increase my radius, or must I decide between foregoing the increased business just beyond my reach or, taking the bull by the horns, build another station?

Unquestionably the gas engineer has the advantage of the electrical engineer in his method of distribution, but he has this advantage solely through the apathy of the electrical engineer and not through any inherent right. The facts are indeed the other way, for the pressure at which the gas engineer may distribute his gas is limited to that at which gas can be burned at its most efficient rate. No such limitation is placed upon the engineer who distributes gas for fuel purposes. Compressed air is being daily delivered through 20 miles of pipes with a pressure at the point of delivery of approximately 100 lbs. to the square inch and a leakage loss not to exceed 10 per cent., and gas for fuel purposes can be delivered through the same pipes at the same pressure and leakage, whereas for illuminating purposes the final pressure is limited to a fraction of a pound in pressure to the square inch, but even under these conditions the Consolidated Gas Light Company of New York is distributing gas from the Harlem River clear down to the Battery—a distance of 13 miles, and the Gas Light and Coke Company of London is delivering gas over 70 miles of territory through 2,000 miles of mains to a distance of 17 miles from its stations. On the same investment in pipes, therefore, a far greater gas delivery can be made for power purposes than can be made for lighting purposes and the electrical engineer who will deliver his energies to his centers of distribution in the gaseous form will have an enormous advantage over the gas company by reason of his ability to distribute his gas at greater pressure.

But he must be careful not to throw away the advantage thus gained by distributing his electrical energy over too extended areas. Mr. Perry was convinced that the tendency to increase the radius of distribution is in the wrong direction and that the solution of the electrical engineers is in the contrary direction, viz., in increasing the number of centers and decreasing the radii.

Mr. Perry then gave a table showing volume of gas which can be delivered at various pressures through various lengths of pipe.

The extreme cheapness of transmission of gas distribution enables the gas manufacturer to locate his generating plant where real estate, coal and water are cheap, and thus we find all of the gas plants in New York City located on the water front, whereas the principal electric light plants are placed on the most expensive land at such a distance from the water front that the hauling of coal and the disposal of the ashes costs one of the most favorably located of these plants 54 cents per ton on an aggregate of some 50,000 tons of coal per annum. Water for condensing or other purposes costs the largest consumers in New York 10 cents per 100 cubic feet, rendering it in most cases more economical to operate engines non-condensing than to run them condensing.

These facts and the further fact that the gas manufacturer utilizes the majority of his generating plant continuously and at its maximum efficiency, explain why on an investment of less than one-third he can accomplish essentially the same results more cheaply than can the electrical engineer.

The gas engineer by reason of the facility of storage of his product has practically no standby losses and his total investment is constantly worked to nearly its maximum capacity. About the only part of the plant not so continuously employed is his distributing mains, for these are not employed to their fullest capacity except for an hour or two each day. He has avoided these inefficiencies over a portion of his system, however, by establishing distributing gas-holders at con venient centers so that the mains connecting these distributing tanks and the generating plant are continually employed, and only those radiating from these centers fall short of their full earning capacity.

---

[1] Abstract of a paper read before the Northwest Elec. Assoc.

Mr. Perry's suggestion for rectifying the existing conditions was to locate a gas generating plant with regard to economy of land, fuel, etc., and install at this point a large gas-holder so that every dollar of investment at that point would have a maximum earning capacity. Taking advantage of the greater economy of gas over electrical transmission, transmit this gas to local centers of distribution. At these points smaller gas-holders should be erected so as to enable the gas mains to be used to their maximum capacity. Gas engines would take the place of steam boilers and engines, less space would be required and standby losses entirely avoided. If the load line were such as to warrant the introduction of storage batteries, these would supplant the local gas storage and the real estate at this point, and dynamos, engines and labor would all be employed continuously to their best advantage. In fact every dollar of investment from the gas generating plant to the electrical plant at the local distributing center, including the gas mains, would be employed to its best advantage leaving only the distributing mains to be employed under a low load factor.

SAFETY DEVICES FOR ELECTRICAL CIRCUITS.[1]

BY PROF. W. M. STINE.

THE author gave the results of an extended series of tests on fuse wires which he summed up as follows: 1. Covered fuses are more sensitive and have a lower carrying capacity than exposed ones. 2. Fuse wire should be rated for its varying capacity for the lengths ordinarily employed. 3. Fuse blocks should be made with greater distances between the terminals. 4. Fuses should be removed from time to time, as they become coated or fouled. 4. The time element should be considered when protecting parts liable to burn out. 6. Fuses up to 5 amperes should be at least 1½ inches in length, one-half inch to be added to the length for each increment of 5 amperes. 7. Except for smaller sizes, flat fuses are more reliable than round wires. 8. Round fuse wire should not be employed in excess of 30 amperes capacity. For higher currents flat ribbon exceeding four inches in length should be employed. Prof. Stine also pointed out the duty of the manufacturer. The ordinary method of marking fuse wire is entirely inadequate. Each spool of wire should be accompanied by a curve or table clearly setting forth the carrying capacity for varying lengths. Better still, the use of wire should be discontinued, and fuses sold already mounted to copper terminals, plainly marked with their normal rating, which should be at least 80 or 90 per cent of their fusing currents.

Prof. Stine objected to screw fuse plugs, not only because the length of wire is too short, but because poor workmanship and liberal use of solder raises their fusing points to a dangerous degree. As a rule, their actual fusing points are double their marked ratings.

In treating of mechanical cut-outs Prof. Stine premised that these apparatus involve points which admit of extended experiment and discussion—questions which relate mainly to the form of the actuating apparatus, but which, for our present purposes, need not be entered into. A comparison with the thermal cut-out is at once suggested. The fuse wire is an indirect device. The electrical effect must be transformed into heat energy and the distribution of heat in a metal is always slow. In a mechanical cut-out whose vital member is an electromagnet, an excessive current acts immediately to open the circuit. There is here no transformation of energy and tardy distribution, as direct advantage is taken of the energy of the magnetic field which always accompanies an electrical current.

There is but one principal factor influencing the reliability of the magnetic cut-out—the sticking of the mechanical parts. In those tested, this was found to be so small it was negligible. What would occur should the cut-out not be opened for months, and the parts become corroded, one cannot say.

In the choice of mechanical cut-outs simplicity is of great importance. The electromagnet should contain but little iron, and the mechanism for opening the circuits should be powerful enough to insure prompt and regular action.

In view of the foregoing facts the question arises, when to employ a fuse wire, and in what cases should the circuit-breakers be used. This is a question to be decided by individual judgment, enlightened by a proper knowledge of the properties of both. It is advisable to keep fuse wires off switchboards entirely—they do not afford the requisite protection, and, besides, foul the board.

For protecting motors, except in the smallest sizes, fuses are not reliable, and circuit breakers should invariably be used. The same plan is to be recommended for protecting transformers, though at present it seems rather impracticable. But in this same connection it is to be remembered that electromagnetic cut-outs act as efficient choking coils and lightning protectors. For such places as distribution closets and tap circuits the fuse leaves little to be desired, and it would be well were it confined to such uses exclusively.

Another matter which demands fuller treatment than can be here given to it is the protection of large electromagnets against high electromotive forces of self-induction. Transformers and the fields and armatures of dynamos and motors are here referred to. The subject has been treated at length in a recent article by the writer. (The Electrical Engineer, Nov. 25, 1896, p. 532.) Only a few brief suggestions can here be offered. Due provision should be made for absorbing circuits across the terminals of all electromagnets. The simplest form which this protection can assume is a circuit of one or more incandescent lamps placed across their terminals. If the exciting currents in such magnets be suddenly interrupted, the incandescent lamps will absorb the energy which otherwise would spend itself in piercing and burning out the insulation.

INCONSISTENCIES IN ELECTRIC WIRING.

BY HARRY N. GARDNER.

A SHORT article in a recent issue of a scientific publication commented upon the advancement made during the past few years in the methods of electric wiring. Certainly, with increasing knowledge upon the subject, improved methods have been the necessary result. But there are still many inconsistencies in the manner in which the improved methods are applied, and there is yet opportunity to improve upon the methods.

Many merchants who are compelled to go to the expense of having porcelain used to remove wires from contact with a varnished ceiling ask why it is any more permissible to encase the wires in a wooden moulding, and are told that the moulding is waterproofed with shellac or paint. While they will sagely admit that "that electricity is a great invention," it is difficult for them to understand wherein is the difference between a wooden moulding and a wooden ceiling, each with two coats of varnish. Can any electrician or insurance inspector explain this for them?

While there are still some such inconsistencies in the methods, present methods of electric light wiring, when carefully followed, offer the safest system of lighting now in use, but how often does the lack of observance of some minor detail in construction counteract the care bestowed upon all the other parts, and thus make the danger as great as though the earlier, cruder methods were followed?

Many wiremen will use the utmost care in doing their work in a certain manner, because " the rules say" that is the way it should be done, but in some detail upon which the rules are silent they will perform their work so as to cause more danger than would result from a non-observance of all the rules.

Supervising engineers and insurance inspectors also, no matter how much care they may bestow upon the broader details, often leave unspecified and unobserved some of these little things that counteract the good which would otherwise result from their care.

If the dictates of insurance inspectors could all be brought before them at one time, even they would have to admit the inconsistency proved by such an array of evidence. True, many of their oversights result from the inspectors being unable to inspect the entire work, in cases where the truthfulness and carefulness of the wiremen have unwisely been depended upon, but in some instances the blame could not be thus placed. A case was recently noticed where the usual care in other details had been observed, especially in keeping insulated wires well removed from all grounded metal, but a style of rosette had been used upon a stamped steel ceiling in which the metallic rosette ears were in no case removed more than one-eighth inch from the ceiling, and because of the stamped figures of the ceiling, in some cases not over one-thirty-second of an inch existed between the ear and the grounded metal. These rosettes were in plain sight, and the insurance inspector had given a certificate approving the work.

How many engineers who spend hours in studying out the more important features of a set of specifications, ever thought to specify or even suggest, where gas and electricity are planned for in combination, that gas nipples should be left protruding beyond the plaster but little more than the threaded part? Of course, insulation joints must be used, but many times where gas nipples protrude two or three inches, the soldered joints or horse shoe cut-outs in the fixture canopies are folded back so as to bring them in contact with the pipe above the insulation joint. Of course, such a thing should not happen, no matter how long the nipple, but care in the first place in bringing the insulation joint near the ceiling, by using a short nipple, makes it so that it could not happen, no matter how careless may be the person who puts up the fixtures.

---

[1] Abstract of a paper read before the Northwestern Elec. Assoc.

The putting up of fixtures often illustrates another inconsistency of applied methods. Great care may be taken in all other parts of the installation, only the most careful and competent workmen being employed, but the fixtures are an afterpart, and anyone can put them up who knows a little about electrical work; perhaps it is a gas fitter or a wireman's helper. Even if there is no danger in the fixture itself, it being noncombustible, there is greater chance therefore for short circuits to cause trouble elsewhere, and is there any other one part of a system that offers more frequent danger than fixture canopies? Frequently there are loose ends of paper ready to be ignited, and in frame buildings, the plaster is frequently off close around an outlet, thus giving opportunity to any fire started under the canopy to communicate with the lath above.

In all canopies there are either soldered joints (if they are soldered), or fusible cut-outs. While it is undoubtedly better to have few enough lights upon each circuit to do away with fixture cut-outs altogether, if they are to be used at all there is no place where a cover over a fuse is more necessary. If soldered joints occur in fixtures they should be particularly well taped, but no matter what the rules say, how many joints are "taped until they are insulated equal to the original insulation of the wire?"

In connecting a dynamo with the switchboard, a representative of one of the larger companies recently had to use a lead covered million and a half c. m. cable. The holes in the floor were bushed with porcelain, and upon the timbers in the basement the cable was carefully run upon large porcelain insulators, but in several places where short bends were made the cable was tightly pressed against the timbers! Even if the porcelain was unnecessary with the lead-covered cable it looked inconsistent, to say the least, to use four or five dollars' worth of porcelain, and then counteract any benefit which might have resulted from its use to save five cents' worth of time.

While there is a difference of opinion regarding the relative merits of metallic conduit and porcelain knob and tube work for frame buildings, it is certain that poor workmanship often counteracts whatever advantage the conduit may have, for carelessness in a single point with metallic conduit will more easily impair the entire system than where porcelain is used.

The superintendent of construction for a company employing thirty to fifty wiremen, recently said that he never furnished crimpers for his men to use with brass armor, but had them use their pliers. It would be almost a miracle in a system of brass armor installed in that way, if the rest of the work was done with proportionate carelessness, if the insulated wire was not in contact with the metallic sheathing in several places, and even if it were not, the liability of the sharp edges of the metal cutting through the wire insulation, thus causing real danger, it certainly is a waste to spend money for conduit installed in that way.

Iron armor is often installed without using a reamer to remove the burrs and fins upon the ends of pipe made by pipe cutters, and such metallic edges are left sticking through the conduit insulation to cut the wire insulation as it is drawn in, or at least so that the insulated wire is left in contact with the metallic sheathing. Again, lead used at the unions is often put upon the ends of the pipe before a thread or two is entered, or within the sleeve itself, leaving it so the lead will squeeze up between the ends of the pipe, thus again giving metallic contact between the insulated wire and the conduit shell. Is it not inconsistent to spend money for conduit to be installed in that way? For what improvement over the old method of running the unprotected insulated wire in the plaster upon brick walls is offered by a conduit system thus installed?

Again, none of these defects may have been permitted to occur, but at the outlets the ends of the conduit are left projecting so that the fixture canopy comes in contact with them. Surely an insulation joint is useless in such a case if the conduit and gas pipe are anywhere in contact, as they usually are, and if the poorly taped joints are in contact with the canopy it leaves little or no benefit to be derived from the use of the conduit in the entire system.

One advantage of metallic conduit, we are told, is that it offers a fireproof protection to any wire which may become heated. But sometimes, especially in brass armor where poor connections are made at the unions, the resistance of the metallic shell is greater than that of the wire upon the inside. In such cases, if a stretch of the shell helps to produce a short circuit, the heating, if there is any, would be outside instead of inside the pipe.

But, we are told, the fuses at proper places should protect the wires so that in case of short circuits the only heating should be in the fuse block. True, but who knows how soon some one will insert a piece of copper wire in place of a fuse?

It may be argued that such slight defects as have been mentioned might exist in hundreds of cases without causing trouble. There are also hundreds of cases where electric lights installed under the old method have been in service for years, and no trouble has resulted. But no one denies the advantage of modern methods, properly followed, over the old; then why, by some such slight defects, leave new methods so that they offer but little real improvement over the old, practically wasting all the money spent upon the more expensive modern style?

To any one informed upon the subject it is evident that many little inconsistencies, such as those mentioned, everywhere detract from the advantages that would result from otherwise carefully installed electric systems. While the fact is apparent, the remedy is not so easy to prescribe.

To the system of insurance inspection, more than any other one cause, is due credit for the improvement of the new methods over the old. A continuation of the strict system of the inspectors, in spite of the occasional inconsistencies on their part, will undoubtedly do much to decrease the little defects. But the existence of the insurance inspectorship is itself indirectly responsible for one cause conducive to poor workmanship. Many business men and builders, when electric wiring is to be done, will not engage a competent man to oversee the work, often not even to do it, but award the contract to the lowest bidder, stipulating only that so many lights shall be wired for, and "an insurance inspector's certificate furnished." Many architects who get out a separate set of specifications for the plumbing, will devote to the electric light specifications the single sentence "outlets to be wired for as shown on plans, work to be subject to approval of underwriter's inspector."

Thus is saddled upon the insurance inspector a duty for which he was never intended, and an opportunity is given a "cheapest bidder" contractor to flourish, for he can figure on doing parts of the work over which the inspector has no jurisdiction in a much cheaper manner than would his more conscientious but unsuccessful competitor. He will hire cheap help and strives to cover up defects so they will be unnoticed by the inspector, or, if noticed, he counts on his ability to "work" the inspector, and so have them passed. The superintendent of construction before referred to, admitted that it cost him considerable to "buy cigars, etc." (he did not say what "etc." might be) for the inspector, but added that he always managed to have his work passed.

If architects and others having installations to make would engage the services of a competent man to make a complete set of specifications, it would give the conscientious contractor an equal show with his tricky competitor, and less poor work would result. If only reliable contractors should be considered at all in the letting of contracts, still more good would be accomplished.

Workmen themselves present an inconsistency in regard to good workmanship. While experience is, of course, necessary, many experienced workmen are responsible for little defects which weaken their otherwise good work, in fact, the last ten years have offered such opportunities for advancement in electrical work, that the man who has had ten years' experience as a wireman, because he has had ability to become no more than a wireman, is liable to make mistakes of which his wide awake helper of six months' experience would not be guilty.

If engineers, architects, their clients and the inspectors would co-operate in making it impossible for any but reliable contractors to secure contracts, if contractors would hire only competent workmen, if workmen would use greater care in the little details, if labor unions would devote more attention to instructing their members to become more competent to perform their work properly, than to quit work promptly, there would be no little inconsistencies to write about. But perhaps there will also be no need of electric lights in the millenium.

FOSTORIA, O.—A committee of citizens appointed by the city council have entered into a contract with B. G. Tremaine and associates of Cleveland, whereby they agree, in consideration of a bonus of $10,000, to erect a factory for the purpose of manufacturing incandescent electric lamps. The factory will be a two-story brick, and will have at the start a capacity of 4,000 lamps a day. The company will have an authorized capital of $100,000, all of which is taken.

DE PUYDT AND PONCIN'S CONTINUOUS CURRENT COMMUTATORLESS DYNAMOS AND MOTORS.

We have received from Messrs. A. de Puydt and M. Poncin, electrical engineers, of Birkenhead, England, the following communication:

We think it will be of some interest to your readers to learn that we have designed and constructed a continuous current dynamo without commutator. We know that several dynamos of that description have been made and tested, but they were all experimental machinery, without practical utility.

As far as we know, the principal cause of these failures has been mechanical difficulties of construction in dynamos of that description, based on the present rules of magnetism and electricity.

We may now say that for some years past we have been compelled to think that at least one of the fundamental rules of magnetism and electricity was wrong, because it is, if not in contradiction, at least in non-accordance with other well known phenomena of nature.

These reflections have led us to try something other than the present rules would suggest and so have enabled us to avoid the mechanical difficulties stated before, and, we believe, with full success.

First, we have made a very small dynamo for the purpose of justifying our reasoning, and on it giving the expected results, we have made a 200 horse-power dynamo for the purpose of testing efficiency, etc.

As soon as we are clear with our patents we shall be very pleased to show one of our commutatorless dynamos in our Birkenhead works to any competent person applying by letter.

DEAD WIRE ON ARMATURES.

BY PROF. W. A. ANTHONY.

The article by M. R. Pfund, in your issue of Feb. 10, 1897, upon "Dead Wire on Armatures," leads me to offer a few suggestions. In my view, the question whether a given portion of wire on an armature is "dead" or not, depends not so much upon whether it is actually cutting lines of force or not, as upon whether it can, by proper design, be made to aid in producing a higher total e. m. f. in the machine, or, can be dispensed with so that while the e. m. f. of the machine remains the same, its armature resistance is made less.

Take the case of the Gramme ring. There is no question that the armature coils must enclose an area. There is no question that the e. m. f. of the machine is measured by the mean rate of change in the number of lines of force that pass through that area. The number of lines of force that can practically be made use of in the area enclosed by the armature coil depends upon the quality of the iron of the core and the speed of the machine. At a certain speed only a certain degree of saturation is permissible, as too high a saturation would cause too great a development of heat.

Assuming this maximum permissible number of lines to exist in the core, the number passing through the area enclosed by any one coil changes from zero to this maximum and from this maximum to zero twice in each revolution. Now, it is impossible for the lines to get into or out of the area enclosed by a coil without cutting the wire enclosing that area somewhere, and it is immaterial where, whether throughout the whole length of the wire or only a small part of it, the e. m. f. developed is the same in any case.

If, by the use of external pole pieces only, the permissible number of lines is sent through the core, then only the outside wires cut the lines and the e. m. f. may be considered as developed there. But there would be no advantage in adding internal pole pieces with a view of rendering active the wires on the inside of the ring, for by the hypothesis all the lines that are permissible already enter the core from the outside, and if lines enter from the inside it will be necessary to diminish the number entering from the outside, so that the total number of lines cut by the coil is not increased; therefore, no increase of e. m. f. can be developed under the conditions assumed by the use of internal pole pieces and so rendering the inside wire active. The inside wire, therefore, is not dead in the sense that it is useless unless the design of the machine is such that a useless length of wire is employed to enclose the given area.

Mr. Pfund refers to Mr. Hering's experiment in which he obtained, by oversaturating the armature core, an inverse e. m. f. in the inside wire. Note that this result was obtained by oversaturation of the core. The total e. m. f. of the machine was then greater, notwithstanding the inverse e. m. f. of the inside wires than it was at a less degree of saturation when the inside wires gave no e. m. f. In other words, the increase in e. m. f. in the outer wires was more than sufficient to make up for the inverse e. m. f. in the inner wires.

The total e. m. f. of the machine in this experiment was undoubtedly greater than could be practically maintained without overheating the armature core. The coils could not have been made to cut any more lines by trying to cause some to enter the core from the inside. Why then consider the inside wire as "dead" or useless? It is needed to enclose the area. If all the lines that can practically be used in that area can be introduced by one side so that only one-half, or one-fourth, or even one-tenth the wire cuts those lines, the machine will still give the maximum e. m. f. of which it is capable.

Mr. Pfund's Figs. 2, 3 and 4, and the accompanying explanation show that he has some erroneous idea about the development of e. m. f. in a magnetic field. It is the wire in the position shown in Fig. 3 which has developed in it an e. m. f., while in the positions shown in Figs. 2 and 4 no e. m. f. is developed.

DEAD WIRE ON ARMATURE.

BY W. C. BOYRER

I note in your issue of Feb. 10 an article by Mr. Richard Pfund, relative to the action of "dead wire" on dynamo armatures. While I agree with the author as far as the results obtained are concerned, I think his method of obtaining them is somewhat misleading. He speaks of a stationary conductor, with lines of force suddenly shot across it. In the practical working of dynamos, we have, on the other hand, a moving conductor in a constant field; so that his method does not treat the case as it actually exists.

In the accompanying diagram let A and A' represent the cross-sections of two conductors on a ring armature, let lines of force be passing in the direction indicated by the arrows, and let the direction of rotation of the armature be clock-wise. Let us also suppose there is no leakage across the armature, and no distortion of field.

The coil A having a motion at right angles to the lines of force will be cutting them at a maximum rate and will therefore be generating a maximum e. m. f. That part of the coil lying on the periphery of the armature, cuts lines in such a manner as to produce an e. m. f. tending to send a current away from the observer; while, since there is no leakage, that part of the conductor lying on the inside of the armature cuts no lines and produces no e. m. f.

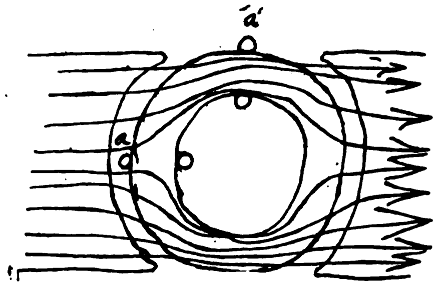

FIG. 1.

Since there is no distortion of field, the coil A' having a motion parallel to the lines of force, does not cut them, and therefore produces no e. m. f.

The introduction of leakage has the effect of producing a field across the air space inside the armature. When this obtains, that part of the coil A lying on the inside of the armature will cut lines in such a manner as to produce an e. m. f. antagonistic to that generated on the periphery; while the coil A' will still generate no e. m. f. in any of its parts.

The introduction of distortion of field simply changes the position of the coil A' at which it generates no e. m. f.

These considerations bring us to the conclusion that in the practical working of a ring armature, since there is always some leakage across the armature, those portions of all active coils lying on the inside of the armature generate more or less e. m. f., and this e. m. f. is always antagonistic to the e. m. f. of the generator.

PITTSBURGH, PA. A very complete electric power and lighting plant is now being placed in position in the extensive works of the Shoenberger Steel Company, Pittsburg. The power plant consists of one 400 horse-power vertical cross compound engine direct connected to 225 kilowatt generators, and one 175 horse-power vertical compound engine direct connected to 125 kilowatt generator. The engines were furnished by the Ball Engine Company, Erie, Pa., and the generators by the Siemens-Halske Electric Company, Chicago.

ELECTRIC LIGHTING

THE ENCLOSED ARC LIGHT.—V.

BY L. B. MARKS, M., M. E.

IN the candle power curves, Figs. 9 and 10, which I have given for comparative purposes, the same difference in distribution of light will be noticed as in the case of the efficiency measurements. The mean hemispherical candle power of the enclosed arc as determined from the curve is 431, the watts per candle being 1.17. The corresponding values for the open arc are 425 and .953. In the case of the enclosed arc the maximum candle-power as may be deduced from the curve, is 595, while the corresponding candle power of the open arc is 1080. The figures for the open arc are taken from a brand of carbon in extensive commercial use in the United States. In the candle power curve for the open arc the readings begin at 200 instead of 0.

It will be noted that although the maximum candle power of the open arc is almost twice that of the enclosed arc the mean hemispherical candle power of the former is a trifle less than that of the latter; in general it will be found that because of the comparatively deep crater in the positive carbon of the open arc, the difference between the maximum candle power and the mean candle power is very great; in the enclosed arc, on the other hand, especially when the bulb is made of a slightly translucent glass, this difference is very slight.

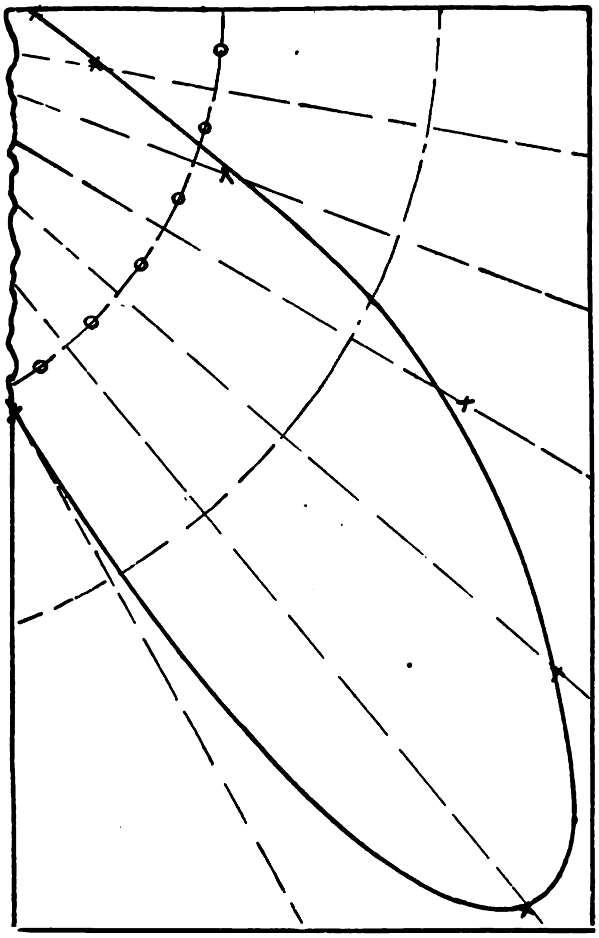

FIG. 9.

A comparative test of candle power of the open and enclosed arc lamps, respectively, was made recently by one of the illuminating companies, and I submit the report of same to you, Table VI. The candle power measurements represent the relative illumination produced in actual practice. The open lamp was provided with the usual opal globe in common service here, and the enclosed lamp with an opalescent inner and a thin opal outer globe such as used in the standard enclosed arcs. For the same wattage the excess of candle power was slightly in favor of the enclosed arc lamp.

It is difficult if not impossible to obtain a true value of the effective illumination of an arc lamp, especially of the enclosed arc, in terms of candle power. In interpreting the candle power tests of arc lamps this fact must be taken into consideration. The quality of the light emitted by the enclosed arc differs from that of the open arc and on this account comparative candle power measurements must always be lacking more or less in truly representing the relative values of the lights. I have found in some cases that an enclosed arc, although producing actually less candle power than an open arc, has given more available illumination, and on this account met the demands of the consumer better than did the open arc. The number of open arc lamps which are daily being displaced by enclosed arcs in the city of New York alone is the best evidence in proof of the fact which I have cited.

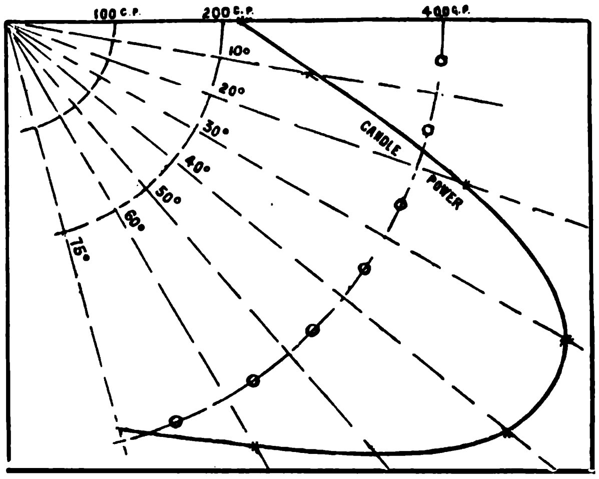

FIG. 10.

TABLE VI.

Candle power test; "Pioneer" 4 ampere enclosed arc, and "Ward" 8 ampere open arc.

Mean watts arc, enclosed lamp = 349
" " " open " = 346
Excess of watts, enclosed arc = 1 per cent.
" " c. p. " " = 2¼ " "

Rush of Current.—The amount of current consumed at the start by open lamps run two in series on incandescent circuits, is generally excessive compared with the normal current passed by the lamp. The amount of current consumed by such lamps just after the latter have fed often rises to a comparatively excessive point; this latter is true especially of lamps, the mechanism of which has been clogged with dust or grit in the ordinary course of commercial usage. In the enclosed lamp which you have before you, on the other hand,

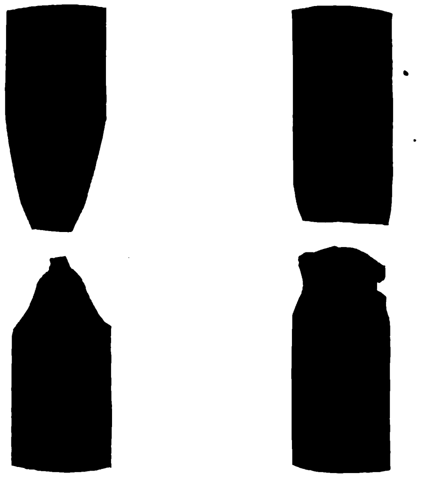

FIG. 11.—OPEN ARC. 6 AMPERES; 45 VOLTS.

ENCLOSED ARC. 6 AMPERES; 45 VOLTS.

the inrush of current, that is, the starting current, is practically as small as the normal current of the lamp; there is no excess of current after feeding as in the other case.

Measurements made on an average pair of commercial open lamps are given in Table VII., and will illustrate the above points. It will be noted from this table that the starting current of the lamps was 25 amperes; at the end of 3 minutes the current had fallen to 16 amperes, but then jumped up again to 21; the normal current was reached after 5½ minutes, the feed having taken place at 7 minutes after start. Thus in this case the starting current was 150 per cent., and the current after feed 20 per cent. greater than normal. With many kinds of open lamps in commercial service the current after feed is often from 50 to 100 per cent. greater than normal. With the enclosed lamp the inrush of current does not exceed the average by more than 20 per cent. and the current after feed seldom rises over 10 per cent. more than normal.

Formation of the Carbon Points and "Building" of the Negative; Observations of the Arc.—You are all familiar with the typical formation of the carbon points of an arc in open air. When the arc is enclosed in a small bulb, however, from which the air is excluded or to which it has very limited access, the carbon points take an entirely different form, even though the current and voltage of the arc be the same in both cases. Here are two pairs of carbon tips, Fig. 11, which have been operated under the same conditions except as to the enclosure. The carbons were burned at 6 amperes in each case, the drop across the arc being maintained at 45 volts. You will note that when the carbons are burned in open air, the negative is well pointed, while the positive tapers at the tip and has a well formed crater. Contrasting this formation with that of the enclosed arc carbon points, you will note that the positive in the latter case has a blunt and almost square tip, and the negative, instead of being pointed, has a "mushroom" formation at its tip. The enclosed arc at the voltage cited was 1.7 millimetres long, and the open arc almost 3.5 millimetres long between the tip of the negative and the center of the crater in the positive.

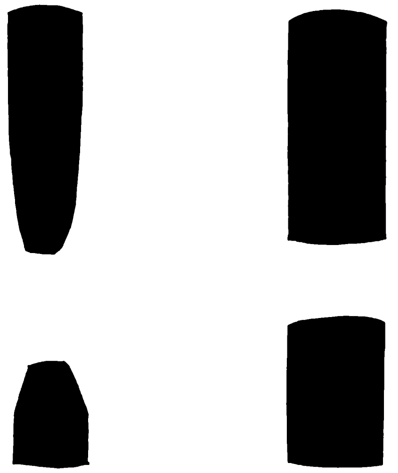

Fig. 12.—Open Arc. 6 Amperes; 45 Volts. Enclosed Arc. 6 Amperes; 85 Volts.

When the voltage of the arc is increased, the carbon points assume a different shape. Fig. 12 is a reproduction of carbons of the same quality and diameter as the last; these carbons were burned at the same current, viz., 6 amperes, but in each case the voltage was raised from 45 to 85. You will note that the formation of the carbon points in open air at 85 volts is entirely different than at the lower voltage; the positive carbon is eaten away for a greater part of its length and has no perceptible crater; the negative carbon instead of being pointed, is rounded off at the tip. In this case the arc was about 15 mm. (9-16 in.) long and "flamed" continuously. The formation of the points in the enclosed arc under the same conditions as to current and voltage is in striking contrast to that of the open arc. You will observe that the points are flattened and are indeed almost square; the positive and the negative tips, respectively, have almost the same shape; the arc in this case was 9 mm. (⅜ in.) long.

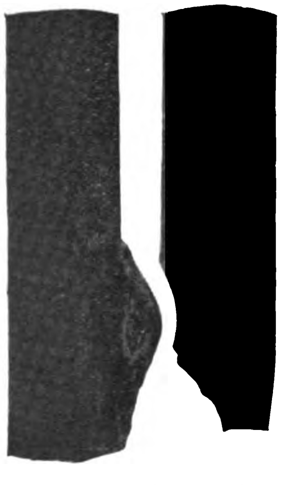

Fig. 13.—Graphitic Nib on Side of Carbon Negative.

The "mushroom" deposit or nib on the negative carbon which has been referred to several times, consists of graphitic carbon, which is deposited electrolytically on the lower carbon by the action of the arc. The deposit of this carbon is in no sense due to gravity as the same formation takes place if the current is reversed, in which case the graphitic bead forms on the upper carbon. When carbons are operated in the enclosed arc at the same voltage as is ordinarily used in an open arc, this nib will always form on the negative, provided the access of oxygen to the enclosure is very limited. When the voltage is raised to a sufficient degree, however, this nib is eaten away or its formation entirely prevented; in the last

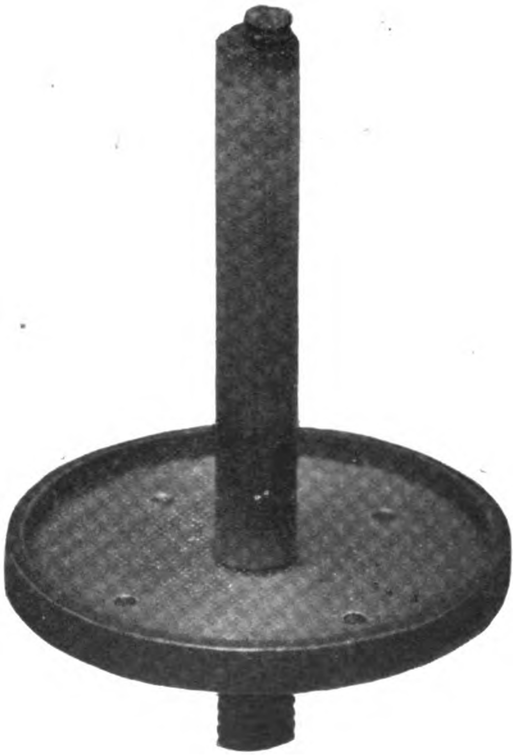

Fig. 14.—Metallic Negative with Graphitic Carbon Nib.

case the carbon particles from the positive while in transit to the negative are combined with oxygen to form carbonic acid and carbonic oxide gases. The point at which the electrolytic deposit ceases to be fixed, depends upon the current passing, the voltage of the arc, the amount of free oxygen present, and other conditions. The voltage of the arc in the high potential low current enclosed lamp is from 80 to 85, but even when this voltage is decreased to 70, as occurs sometimes on account of fluctuations on the circuit, the graphitic formation does not take place at small currents; when the voltage falls appreciably below this point the nib may make its appearance on the negative. See Fig. 13.

The attempt to utilize this principle to secure an indestructible negative has already been alluded to in the case of the metallic negative with the carbon nib, shown in Fig. 14. In all cases where such negatives were used, it was of course necessary to operate at a low voltage in order to preserve the deposit intact. At this low voltage the arc is very short and frequently unsteady; moreover, the difficulty of adjusting lamps to meet the conditions required is very great. Aside from other disadvantages there is always a deposit of uncombined carbon on the walls of the enclosure when a lamp is operated at low voltage in this manner. The "building" of the negative becomes quite marked in some cases where a more powerful current is passed. I have known an instance where the negative actually increased almost 2 inches in length during a run of 11 hours, the mean current being 10½ amperes and the mean tension of the arc 50 volts.

LATEST TYPES OF GENERAL ELECTRIC SEARCH LIGHTS.

THE use of electric searchlights on board vessels, not only of the navy, but those of the merchant marine, as well as on yachts has, within recent years, been steadily growing, as improvements in the mirrors and the operating and controlling mechanism have given to the owners and Government reliable projectors. All the fine war vessels of the new fleet, the ocean, Sound and Lake steamers are fitted with searchlights of tremendous power and range, and almost every steam yacht with any pretensions is equipped with its pilot house projector. The searchlight in the navy is the night-heliograph, so to speak, and beyond its main use to show the whereabouts of an enemy's attacking boats, or the equipment and lay of an inimical coast, its value for signaling purposes cannot be overestimated. The magnificent spectacle of the searchlight beams, as the signal codes of the warships, gathered in New York Harbor on the occasion of the Columbian festivities, will remain an unforgotten incident.

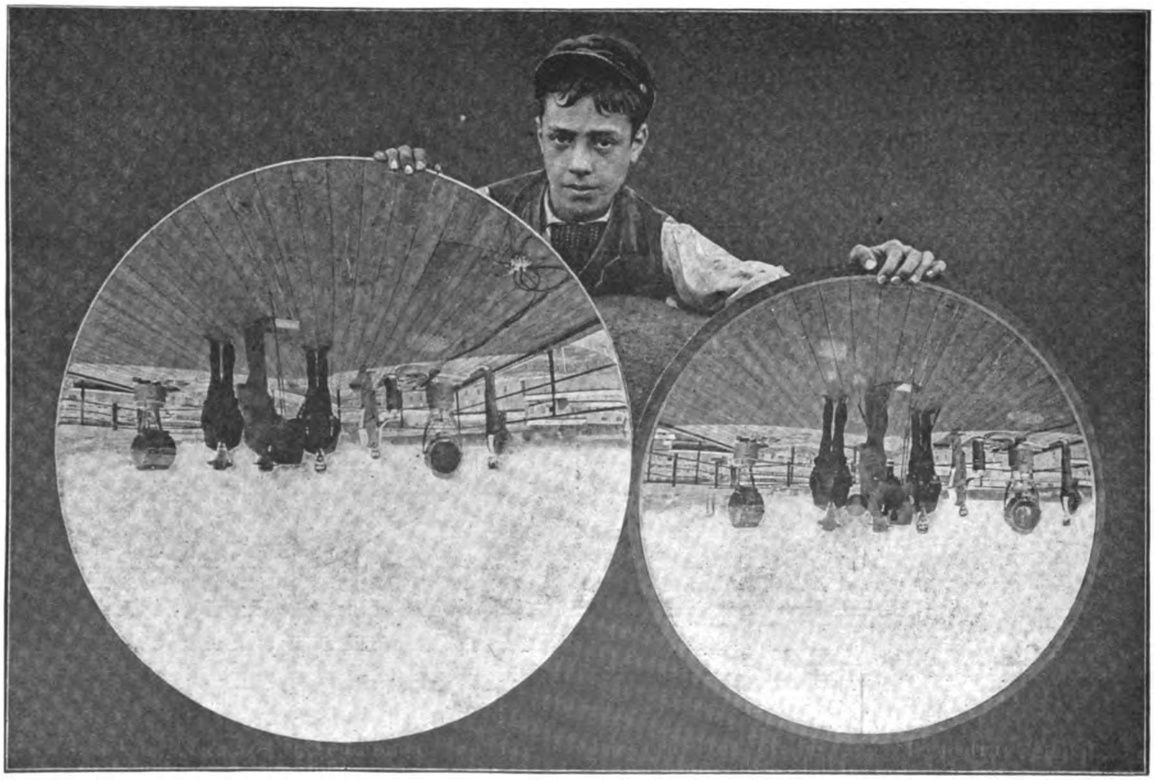

FIG. 1. –SEARCHLIGHT REFLECTORS.

In the manufacture of a perfect searchlight are two main parts, each of which must of itself be perfect—the lamp and the reflecting surface—and unless the greatest of care is given to the design and workmanship of the first, and the grinding and polishing of the mirror, the result must be failure or only semi-success. The former requires electrical and mechanical knowledge of the highest grade, the latter grinding and polishing machinery operating with mathematical accuracy. Up to quite recently, the mirrors for searchlights manufactured in this country were imported from Germany and France, at considerable expense, but when the General Electric Company decided upon the manufacture of the projectors on an extensive scale, it cast about for a manufacturing optician who could be trusted to develop mirrors of as high a grade as those of European make. A firm was found, but it took three years of the most painstaking experiment to bring its mirrors to the necessary degree of perfection. To-day, the mirrors used in the projectors of the General Electric Company are of American manufacture and are equal, if not superior, to those which it had hitherto imported, and it is for that Company alone that these splendid examples of the opticians' art are made.

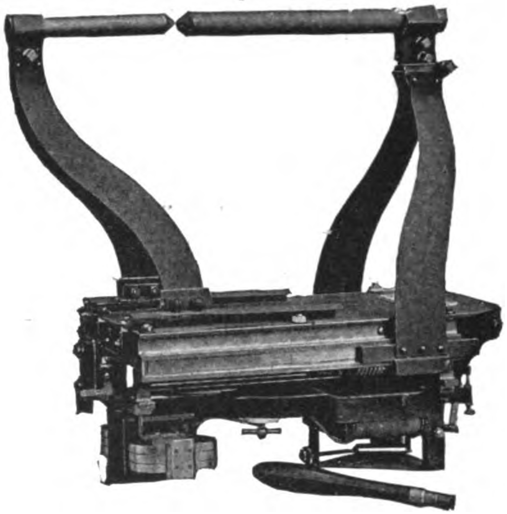

FIG. 3.—HORIZONTAL SEARCHLIGHT LAMP.

At Schenectady, N. Y., one entire department of that company is occupied in the manufacture of projectors. It is located in a building on the corner of which a square tower has been erected carrying a railed platform. It is from this that tests are made of the power and range of the searchlight beams which sweep over the wide expanse of the valley of the Mohawk. A system of distances and intensities has been calculated by which the carrying power of the beam is gauged and the capacity of the projector tested.

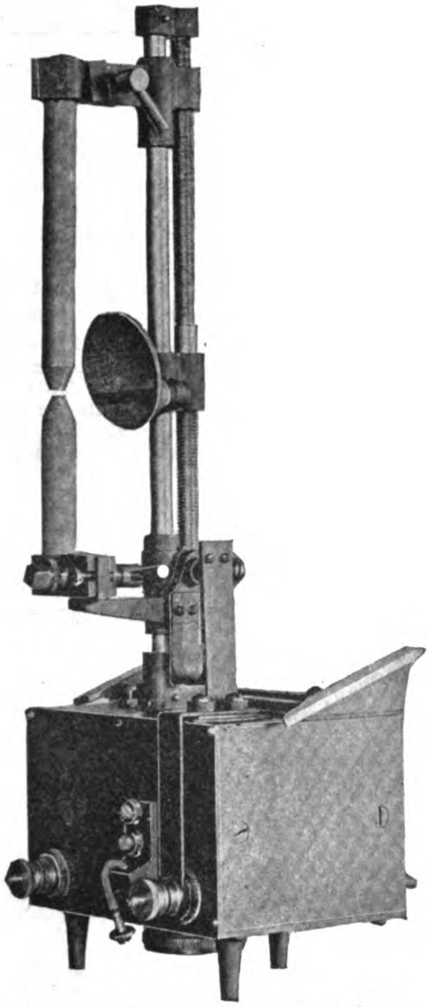

FIG. 2.—INCLINED SEARCHLIGHT LAMP.

The light reflecting surface is a silvered glass concave lens, so ground that when the arc of the lamp is in its focus, the reflector beams which proceed from the mirror are parallel. Two types are used—the Mangin and the parabolic—the former having two spherical surfaces of different radii, the reflection and refraction causing the rays to be projected in straight lines, the latter having true parabolic surfaces. Still a third type is used where the illumination of a large area at short range is desired—the hyperbolic—but in this case the mirrors are of metal silvered.

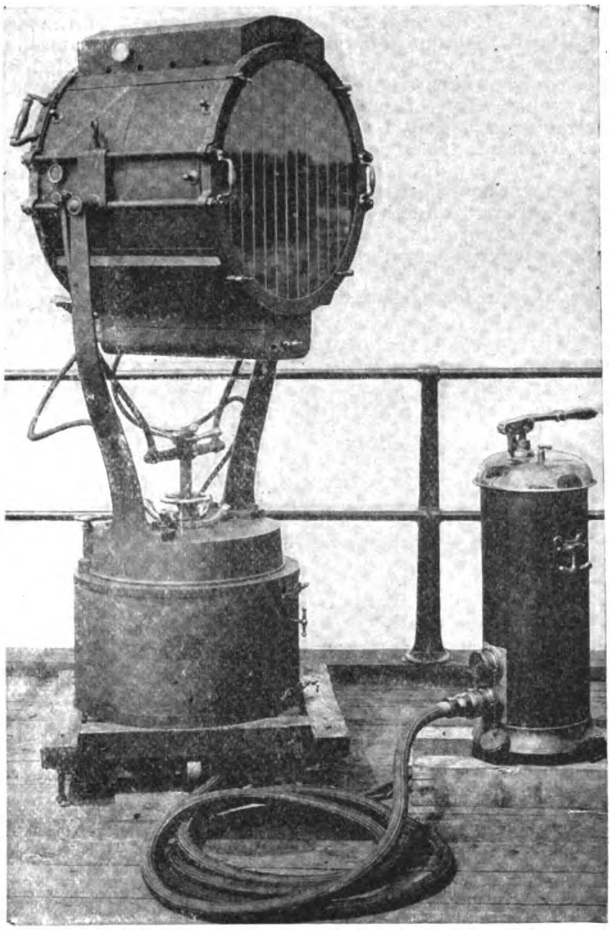

FIG. 4.—ELECTRICALLY CONTROLLED SEARCHLIGHT.

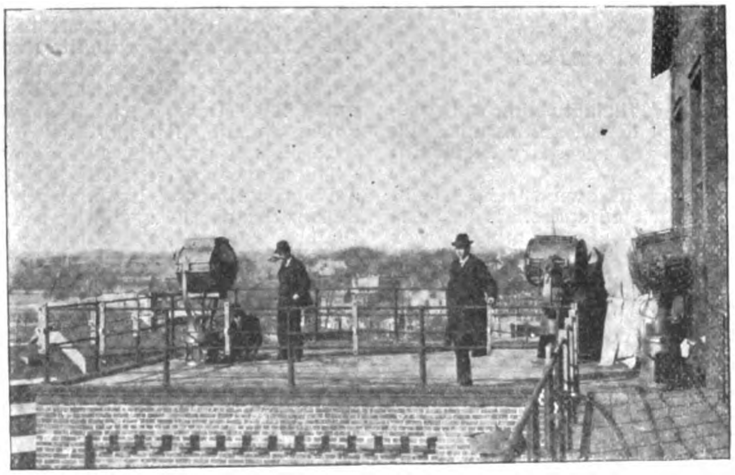

FIG. 6.—THE SEARCHLIGHT TESTING TOWER AT THE SCHENECTADY WORKS OF THE GENERAL ELECTRIC CO.

The lamps are of two types—the inclined and the horizontal—according to the position occupied by the carbons. Both lamps are automatic and focus in feeding. The first type is used in the 12-inch projector, either type in the 18-inch, while for larger sizes the horizontal type has been found the most suitable. All the lamps are designed to operate on direct current incandescent circuits, a regulating rheostat being connected in series with the lamp to bring the voltage to that point at which the best results can be obtained, which is from 40 to 60 volts, according to the current taken.

In order that the person controlling the direction of the beam may most satisfactorily direct it, three systems of control have been devised—pilot house, rope and electrical—depending upon the location of the projector. The electrical control can be applied to any size, but is more suitable to the 24-inch and larger sizes. Horizontal and vertical movement of the drum containing both lamp and mirrors is given by two small motors concealed in the pedestal at the base, and controlled by a single lever set on a small pedestal containing the resistances and switches. By throwing certain disengaging clutches, the electrical control may be cut off, and the projector be controlled by hand. Electrical control allows the projector to be operated from a point almost any distance from it. The same result may almost be attained at less cost by means of the rope control—horizontal and vertical movement also being attained by the movement of a single lever. In this case, however, the distance between operator and lamp must necessarily be limited.

When the projector is set on the pilot house of a steamer, pilot house control is usually employed, the actuating rod passing down through the roof of the pilot house, and terminating in a lever, movement of which gives the necessary horizontal and vertical deflection to the beam.

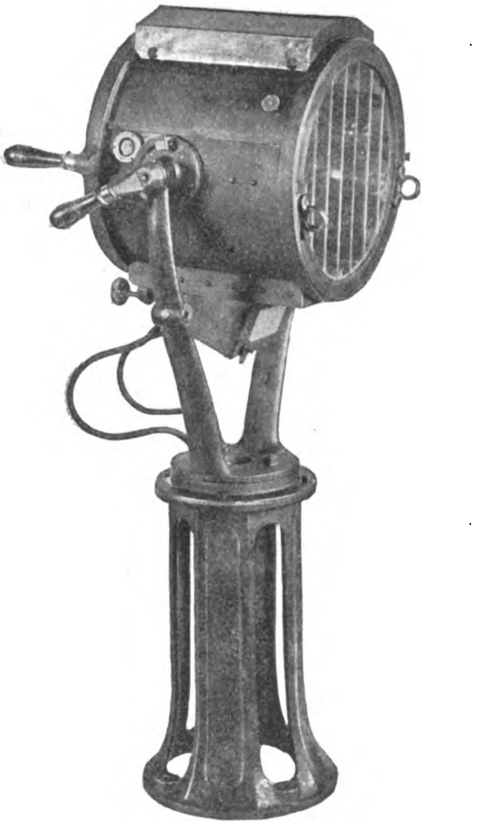

Fig. 5.—Hand-Controlled Searchlight.

The solid beam of parallel rays has its own special use in throwing an intense light upon a restricted space. It is, however, sometimes necessary to illuminate a very much larger space, and instead of a beam to project upon it a horizontal band of light. This is effected by diverging lenses, set in a frame similar to that of the plain glass door, which it replaces when occasion arises for its use.

To allow of observation of the arc from outside without exposing the eye to the blinding glare from the mirror, each projector has a prism let into the side of the drum carrying both lamp and mirror. Through this prism the arc may be observed and regulated. The heat generated by the burning carbons is carried off through ventilators let into the drum at the top and bottom.

The standard sizes of these searchlights are based on the diameter of the reflecting lenses—12, 18, 24, 30, 36 and 60 inches. The greatest searchlight in the world, that exhibited by the General Electric Company at the Chicago Exposition, was of the latter size. This light is now placed on the top of Mount Lowe, in California, whence its beams are visible many miles over the waters of the Pacific.

NEW WHITTINGHAM AUTOMATIC MOTOR STARTER AND QUICK-ACTING SWITCH.

The Automatic Switch Company, of Baltimore, Md., has just brought out the latest designs of Whittingham automatic motor starter and quick acting switch, illustrated in the accompanying engravings.

The operative principle of the starter, Fig. 1, is now so well known, that a description is hardly necessary, but for those not familiar with it we may state that the automatic movement of the rheostat is accomplished by means of a small belt, connected directly with the motor, whereby each revolution of the motor armature cuts out, with absolute certainty, a predetermined part of the starting resistance. This method possesses advantages which are of great value in elevator and pumping work, as it acts as a safeguard against too rapid starting and forcing the motor under an overload. The main feature is that the resistance is always cut out directly in proportion to the speeding up of the motor and can never crowd on current before the armature is prepared to receive it. The construction of the starter has been so modified as to do away with all outside wires, the resistance terminals being completely encased and protected from accidental damage, and the bearings are of graphite and require no oil.

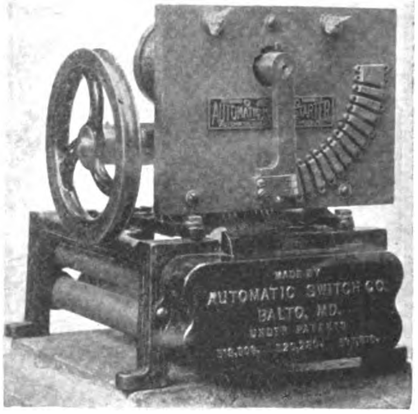

Fig. 1.—The Whittingham Automatic Motor Starter.

Fig. 2 shows a type of quick-acting switch, embodying a number of novel and valuable points which should recommend it to those desiring a substantial circuit breaker for power control. It is designed especially for use in connection with electric pumping and elevator work.

The movement required for the operation of the switch is a reciprocating one, having a stroke of about two inches, which allows the use of a sliding rod passing through bearings on the base castings, and stopping thereon at each end of stroke. The switching mechanism is thus relieved entirely from any strain or pull of the actuating rope, and is operated by the compression springs arranged to give the quick motion, when making or breaking the circuit.

The contacts of the switch are pure copper castings, turned up to a true bearing surface and arranged to engage each other, under spring tension, in a manner somewhat similar to the ordinary street car controller, each set of contacts being detachable and renewable without disturbing the operating parts of the switch.

By means of this switch, in connection with the Whittingham automatic rheostat, open tank, and pressure tank elevators may be operated automatically with satisfaction. It will also be found equally useful in maintaining a certain level in the supply tanks of automatic sprinklers, etc.

Such electric freight elevators as allow the motor to run continuously during the time the elevator may be used, can be more economically operated if arranged to be started and stopped from any floor, as needed, and the apparatus shown is just what is required for the purpose.

A rope, passing up the elevator shaft and over pulleys at top and bottom of same, is connected to the rings of the quick acting switch, which, in connection with the automatic starter, enables anyone wishing to use the elevator to safely start the motor and afterwards cut off the current consumption when it is of no service. There are instances where this saving has amounted to between $200 and $300 in one year.

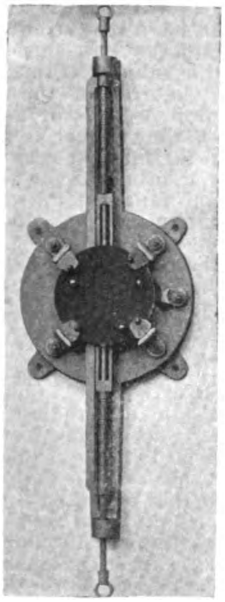

FIG. 2.—QUICK-ACTING SWITCH.

The automatic motor starters are made in sizes ranging from 2 horse-power to 30 horse-power, and the switches supplied in two capacities, viz., 20 amperes and 60 amperes.

The Automatic Switch Company will shortly put upon the market a new form of automatic reversible controller and reversing switch which combines many desirable features and will furnish a reliable means of automatically handling elevator motors without the use of dash-pot or moving magnets.

ELECTRIC PLANT IN THE GOVERNMENT PRINTING OFFICE, WASHINGTON.

THE reports of the chief engineer and chief electrician of the Government Printing Office, Washington, show that during the year 1896 there were no substantial changes in the boiler plant and the power plant. Additions have been made to the steam-heating coil plant, and the entire heating system of the office, with the exception of the business offices, has been put under low pressure steam. The entire office is now lighted by electricity, and all the machinery, except about twenty printing presses, are being operated electrically. When the rest of the presses are connected the office will be controlled exclusively from the dynamo room instead of having to depend on the various engines located at different parts of the building, as formerly.

There are at present connected to the electric lighting mains over 4,200 16 candle-power incandescent lamps. This number will be increased to about 5,000 when additions now under way are completed. Gas is used for the pilot lights only during the hours when the electric plant is not in operation. From January 1 to November there was used in the office 3,877,300 cubic feet of gas less than during the corresponding months for the year 1895.

The application of electric motors to the machinery, owing to its great variety, presented many problems, as well as complicated conditions, which were successfully met and solved. There are now being electrically operated printing presses of all sizes and types, from large web presses, printing at the rate of 11,000 per hour, down to an eighth medium Gordon press; also cutting, indexing, stabbing, folding and case-making machines, signature presses, blowers, ruling and sewing machines. The latter are operated by a one-sixth horse-power motor connected direct to worm gear reducing motion. A reduction in some cases is required of from 1,800 revolutions per minute down to 35.

There are now in daily use 117 direct-connected and 10 belted motors, varying in size from one-sixth to 30 horse-power, making a total of 383 horse-power in electric motors. Added to this is a 30 horse-power motor, used in connection with the Sprague elevator in the new west wing, making a total of 413 horse-power of electric motors thus far installed in the office. Three small engines in foundry, carpenter and machine shops have been stopped and their work is being done by belted motors. During the year there have been no shutdowns or delays in work during the installation of the various motors, which have in every case given the best results.

All the power necessary for the entire work of the office at night, including the running of the large web presses on which the Record is printed, did not amount to within 15 to 20 per cent. of the friction load of the press-room engine and shafting. This is a striking indication of the gains which have been effected over the old belt system by the electrical transmission of power. The chief electrician strongly recommends that the power plant be supplemented by the addition of a large direct-connected unit of, at least, 300 kilowatt capacity, or the installation of a storage battery sufficient in size to supply the office with light during the hours the electric plant is not running. This will not only be more economical, but will enable the plant to be run always at its highest efficiency. The cost for maintenance and necessary repairs of the lighting and power branches of the plant during the year was exceedingly small.

SOME ROENTGEN RAY OBSERVATIONS.

BY W. C. PECKHAM.

IN an article which recently appeared in an electrical journal is the statement that "Röntgen rays will make all sorts of vacuum tubes to glow." I subjected this statement to experiment as follows:

A strong tube was enclosed in a light-tight box and set into action, so that a fluorescent screen glowed brightly. A large number of tubes, both Geissler and Crookes tubes, were tried at the ends and sides of the box. Some of each failed to glow at all; others glowed at both ends and sides. I would say that the Röntgen rays were to be found mostly at the end of the box.

The following tests were then applied to determine if Röntgen rays caused the tubes to glow: Two thick sheets of lead were placed against the end of the box and the tubes were held against these. They glowed better. Then a plate of ebonite a half inch thick; still they glowed as well. Then a plate of brass a quarter inch thick; no diminution of the light. Then a piece of plate glass three-eighths inch thick; still the tubes kept up a glowing through one and one-quarter inches of stuff. Then the fluorescent screen; no glow there, but plenty in the tubes. The screen could find no rays, but the tubes found something to glow with and plenty of it.

It is, of course, evident what it was to every experimenter in electricity. It was electrostatic induction, and all the metal, ebonite or glass one might put in would not hinder it.

Wouldn't it be nice if the papers only printed things that are so, and if all phenomena were traced to real sources before being sent to the papers. We have had a vast amount of false deductions from wrong premises in these X-ray researches.

The strength of the electrostatic induction around an X-ray tube has often surprised me. Sparks fly from my finger tips or my spectacle rims if I approach them too near the tube in action, and I confess I am hardly convinced that the loss of hair and skin, or the sore fingers are due to Röntgen rays, rather than to electricity directly. I have hesitated to subject myself to experiment to prove this, but when I do so I shall proceed in this way: One finger will be exposed bare to the tube to receive its full power; the next will be encased in an ebonite tube; the third in aluminum tubing, and the fourth protected by a heavy U-shaped piece of lead so that X-rays will be cut off from it, but electrical induction will act on it. Thus, finger number one will be acted on by both induction and the rays; number two by the rays, but not by induction; number three by the rays but not by induction, though different from number two; and number four by induction but not by the rays. This, it seems to me, would be conclusive in the case. Has anyone tried it?

VOL. XXIII. NEW YORK, FEBRUARY 24, 1897. No. 460.

WIRING INCONSISTENCIES.

A CONTRIBUTOR to our columns this week draws attention to the inconsistencies which are frequently met with in the carrying out of electric wiring installations, though the facts that he points to are well known and will be admitted as true by all whose experience entitles them to be heard on the subject. Yet it seems a pity that these inconsistencies should be allowed to exist. If, as would appear, the best rules which can be framed by electrical engineers and by the Underwriters are nullified by even slight defects and poor workmanship, is it not time that the proper remedy be applied to give wiring rules their full force? It has often been pointed out that some of the very earliest wiring installations are to-day in successful operation, and we know more than one case where owners of buildings have preferred to forego insurance rather than rip out their old wiring and conform to the new rules of the Fire Underwriters. While we do not advocate so determined a course on the part of owners of buildings, these facts show that there is a great reluctance to the obliteration of old work which has proved to be satisfactory for many years. So far as making the present improved rules nugatory by bad workmanship is concerned, our contributor is probably right in laying the blame largely at the door of the insurance rules themselves. An architect who merely calls for wiring to be subject to the approval of the Underwriters' inspector, gives a direct encouragement to that unfortunately large number of jerry wirers, who by the many tricks known to the trade, are able to successfully hide from the inspector their bad work, leaving only that which is in sight to conform strictly with the requirements. If wiring were not given out to the lowest bidder, but to responsible firms, and more particularly, if the wiring of buildings were done according to the specifications of competent electrical engineers, there would practically be an end to unsafe wiring and a corresponding gain to all concerned, to the insurer, by a reduction in the insurance rate, which would ensue upon a decrease in the number of electrical fires; and of diminished work for the insurance inspectors themselves, who would know that their own inspection has been largely forestalled by that of a competent electrical engineer, who has visited the work and followed it in the course of its installation.

Apropos of interior wiring, we have noticed of late an increasing tendency towards the use of the older materials and even Underwriters' wire seems to be coming into favor again. Thus, in a recent large building now being wired in New York the heavy risers running up through the metal and brick elevator shafts are insulated with the old Underwriters' wire insulation, painted braiding, and tied to porcelain insulators. Of course the use of this type of insulation is only permissible in special locations, but it emphasizes the fact that when properly installed in dry places even the Underwriters' wire can be made to do proper service.

ELECTRICITY AND BURGLARS.

BURGLARY has long been looked upon as one of the fine arts and if this was so in the past, how much more has the art risen in dignity by bringing to its aid all the resources of modern science. Electricity has been largely drawn upon to impede the burglar in the exercise of his profession, but if we are to believe current reports the long suffering burglar is now taking up electricity on his own account, as an aid, and the results of some experiments, magnified by the imagination of the daily newspaper reporter, have, we are told, caused bankers and merchants sleepless nights. The story runs in effect that by means of a current tapped from any convenient street main the skillful burglar can insidiously melt his way through any thickness of iron or steel by means of the electric arc. A recent article in our columns by a writer signing himself "Sleuth" has shown some of the difficulties that would stand in the way of the enterprising safe-breaker, and a communication which we have received from Prof. Elihu Thomson, that eminent authority on electric metal working, sheds additional light on this subject. Prof. Thomson believes that there is no doubt whatever of the possibility of melting through masses of iron or steel of even considerable thickness, provided there is time enough to do it and sufficient current is available; but he thinks it very doubtful, whether any burglar could tap a lighting circuit and obtain the current required, which might range in the neighborhood of 200 to 300 amperes. He would not only need to tap the mains, but he would have to arrange a resistance in circuit so as to produce a stability in the arc formed; that is, he would have to cause a drop of a certain number of volts between the constant potential mains and the arc produced and get rid thereby of a considerable amount of energy. Prof. Thomson does not think that he could, with much less than the current stated, melt into the iron or steel at a rate sufficient to be of much effect in a reasonable time. Furthermore, the use of such an affair produces an intense light and radiant heat, which demands ventilation, particularly as vicious fumes are given out besides. This would seem to make it impossible for work to be done in a restricted space and it certainly could not be accomplished without attracting notice on account of the glare and fitful light, unless very effective screening were used to prevent the light from getting out through windows and attracting attention. To put it in another way, Prof. Thomson thinks the paraphernalia which the burglar would have to carry along and have at his disposal for the attempted work would be a sufficient discouragement in itself, while the time required and the risk of discovery would be so great as to remove the operation from among the possibilities, except under very exceptional circumstances.

That the anxiety of those interested is not imaginary, is shown by the fact that we have received several letters from safe experts asking for further information on the subject. Prof. Thomson's views will go far towards quieting the nerves of the owners of safes containing valuables.

CROOKES BRAIN WAVES.

WE have heard much of late of the scientific use of the imagination and its value in pushing our ideas farther into the realms which are not yet subject to known natural laws, but which may at any time be brought within their domain. A past master, among recognized scientific men, in this use of the imagination is Prof. Crookes, and certainly no living experimenter has so well sustained the claims of those who believe that speculation is in a sense as important as experimentation, and that without it the scientist would be reduced to the level of the alchemist of old. Prof. Crookes' leanings towards spiritualism are well known and hence it is rather a matter for congratulation that he is seeking to place upon a firmer scientific and logical basis some psychic phenomena, closely allied to the manifestations of spiritualism, among them telepathy. We will not here enter into a discussion as to whether telepathy, or thought transference, is or is not an established scientific fact; evidently Prof. Crookes assumes that it is and has recently given a tentative explanation of the phenomenon. Without entering into all the details of the explanation leading up to the final theory, it may be said that Prof. Crookes divides vibratory phenomena into various groups, each of which finds its responsive chord within the human organism. Passing through the vibratory regions of sound, heat, light and electricity, we reach the Röntgen rays, and ascending still higher in the scale, it does not, according to Prof. Crookes, require much stretch of the scientific imagination to conceive that at the sixty-second or sixty-third step, representing vibrations requiring for their numerical expression nineteen digits, the trammels from which rays at the sixty-first step were struggling to free themselves have ceased to influence them, and that these emancipated rays pierce the densest medium with no diminution of intensity, and pass unrefracted and unreflected along their straight path with the velocity of light. Prof. Crookes then assumes the existence of rays of still higher vibration, waves of ether ceasing to have the properties of those known to us and overcoming all obstacles caused by distance or intervening matter. May not these rays, he asks, enable intelligence to be transmitted from one sensitive being to another? "Is it inconceivable that intense thought concentrated towards a sensitive being with whom the thinker is in close sympathy may induce a telepathic chain, along which brain waves can go straight to their goal without loss of energy due to distance?" Prof. Crookes' brain wave theory, anticipated long ago by a similar one from Prof. Houston, is entertaining, if nothing else, but we are inclined to the opinion that some will look upon it as a case of scientific imagination run riot. At any rate, si non e vero e ben trovato. It may be remembered that Mark Twain once, speaking of theorectical or hypothetical science, said it was the finest example in the world of doing the largest business possible on the smallest amount of capital. He might think this case was what he was talking about.

ELECTRIC LOCOMOTION IN NEW ENGLAND.

AT the beginning of the year, in these pages, General Superintendent Fitzgerald, of the B. & O. Railroad, gave to the public a full statement of the work done by his company in electric traction at Baltimore, and made a frank avowal of his entire satisfaction and confidence in regard to the use of electricity on steam railroads. That article seems to have made a great impression, for it has been copied all over the country. Even had it stood alone, as the opinion of one railroad manager, it would have been important, but it becomes more significant when taken in conjunction with the recent remarkable address of President Clark, of the New York, New Haven and Hartford Road, made before the committee on railroads of the Connecticut Legislature. As a matter of fact, Mr. Clark appeared for the purpose of opposing an electric road between Hartford and New Britain, but his whole address was in praise of electricity and his main plea was that his company was already deep in the vital transition work of converting a great system from steam to electricity.

It is not necessary for us to repeat here the details cited by President Clark, as to the experimental work done by his company; it is already familiar to our readers. But the language used in more than one place is worthy of note. Speaking of the first tests at Nantasket Beach, with the regular trolley system, Mr. Clark says: "It was determined, first, that electricity with a given volume of business was a cheaper way of applying power generated in a single station, than by generating it at the head of a train in a locomotive; and, second, that it was no longer a plaything, but would answer for serious work." He then went on to describe the third rail experiments, and bore testimony to the wonderful ease, efficiency and economy of transmission, as well as to the success in operation.

We come now to the pith of Mr. Clark's neat little argument, namely, his remark: "You may tell everybody who is engaged in investing their own or anybody else's money in lines competitive with steam lines, that they cannot long prosper when the day comes to lay down third rails in this country. * * * There is no mistake about this use of electricity so far as we can see." In other words, progressive steam roads will hold their own against trolley parallels by running trolley cars themselves, with the third rail system; and we do not see how they can then fail to retain much of the passenger traffic that has been leaving them. As we have before pointed out, in discussing this very matter, a main feature in favor of the ordinary cross-country trolley car is its ability to stop anywhere, but even in this respect steam roads run by electricity, with frequent small units can closely rival them, with the advantage of being able to make much higher speed between regular stops on a clear, undisturbed track that the buggy and the dray cannot haunt.

The bottom must certainly drop out of some of these trolley "parallels" when the steam roads thus get down to business and adopt electricity, but none of us can tell just yet how the whole thing is going to work out and adjust itself. It is still very much in the air, and the only obvious thing has been that if something were not done, a large part of the capital invested in steam roads would be in serious peril of being destroyed by the new competition.

ELECTRICITY ON THE ELEVATED.

RIP VAN WINKLEISM in the New York elevated management has cropped out from time to time in the statement that it was presently going to try electricity as a motive power and see if there really was anything in it. Now comes the report that after considerable uncertainty and recent investigation, the Manhattan Railway has finally determined to substitute electricity for steam power on its lines The determining factor appears to be an examination of the Chicago elevated system, running for two or three years past, over which the manager of the New York elevated utters exclamations of delight, as though he had just struck something new and wonderful. In reality, the dense ignorance of what electricity has done and can do, shown by some people high in elevated affairs, is pitiable if real, and shameful if assumed.

However, the public is at last to have electric travel on the "L," and it is to be hoped that the company will give the best that the latest resources of the art now allow, and thus reap some benefit from its long delay. We venture to predict that when it does make the change, it will not continue as now to lose passengers, but will enjoy its fair and normal rate of increase, no matter what the surface lines may do. The estimated requirement of new capital by the company is put at $10,000,000, but the recovery of its ordinary share of the business will more than offset the charges on that sum at 5 or 6 per cent. That the public knows this is seen by the strength at once developed in Manhattan stock. Securities go down usually on a declaration that money must be borrowed, but in this case everybody knows that the return is sure, and the value of the property will improve. All that was needed was a little courage. The Second avenue line is first to be equipped.

"ONE-SIDED" PRIZE ESSAYS.

WE had hoped that so far as we were concerned the comments which appeared in our last week's issue, relative to the one-sided report which our contemporary, the American Machinist, has accused an electrical engineer and contributor to our columns, of being guilty of making, would be the last we had to say on the subject for the present; but as our contemporary has evidently been imbued with the idea that compressed air is not getting a fair show, we cannot refrain from calling to its attention a recent prize essay contest inaugurated by the Iron and Coal Trades Review, of London. This enterprising journal gave as a subject for its prize essay the comparative advantages and disadvantages of steam, compressed air and electricity for power purposes in coal working. The prize for this essay was won by Mr. G. E. J. McMurtrie, A. M. I. C. E., and in the course of somewhat extended investigation and discussion of the subject, the author calls to his aid quite a number of reports of tests made on plants of this nature. It is hardly necessary for us to go into all the details of this most interesting essay, but what our readers and contemporary will perhaps be most interested in are the conclusions which Mr. McMurtrie draws from all the data which he has been able to procure. He summarizes as follows:

"The author has now considered steam, compressed air, and electricity for haulage, pumping, and coal cutting purposes. He has endeavored to show that while probably rope-haulage driven by steam engine at surface, and also rope-haulage driven by steam engine below, with the steam taken down the pit, are more economical than similar plants driven by either compressed air or electricity, yet that when the time has arrived for the haulage to be extended, and for subsidiary engines to be put down electricity and compressed air only can be used. Also, that of the two, electricity, on account of both its greater efficiency and its reduced first cost, is then to be preferred. For similar and other reasons, he has considered that electricity should be adopted for both pumping and coal cutting."

To use a legal phrase, we now rest our case and leave the decision in the hands of Mr. McMurtrie's brother engineers, noting only the curious fact that all these people making "one-sided" reports against compressed air are mechanical or civil engineers by profession, and not electrical, unless they have become such by deliberate choice.

THE tests made by Admiral Bunce's invading squadron at Charleston, S. C., have been very interesting as to the aid that can be given by searchlights to prevent blockade running. There are four heavy ships in the squadron and it appears to be well proved that no runner could pass even so small a squadron as that if the weather conditions allow the searches to be used up to the full measure of their efficiency. On a very foggy night, when the runner would be assuming heavy risks on other accounts, the little dynamite cruiser "Vesuvius" got through, but she tried four times in vain on an ordinary dark night to cut undetected across the fourteen-mile belt of light from the men-of-war. Such tests show that the searchlight is a very useful appliance in modifying the old conditions under which blockades were often run with success. Part of the Charleston tests comprised, it is said, a tabulation of the distances at which specific objects could be picked out by lights of given powers.

LETTERS TO THE EDITOR

SAFE BREAKING BY ELECTRICITY.

An article appearing in The Electrical Engineer of February 3, 1897, under the heading of "Fin de Siècle Safe Burglar" puzzles me to know just what its contributor endeavors to bring out. He apparently strains to emphasize a great difference between laboratory experiments and practical application, without seemingly understanding that the latter is but a natural sequence of the former and evidences a desire to allay all anxiety on the part of bankers, who, he claims, have had shudders of fear, ghostly and terrible, sent through their brains and bodies by a "profoundly scientific and eminently practical" newspaper reporter. If he will stop to investigate a little more closely he will discover that the newspaper reporter has been far more scientific and practical than he himself.

It is evident that "Sleuth" contends that it is not practical to obtain from 350 to 500 amperes at 40 or 50 volts pressure outside of a laboratory or under the condition in which a burglar would have to work. As a matter of fact the experiment under discussion was not made in a laboratory but under exactly the same conditions which in practice would exist and might be made use of by an unscrupulous person for a surreptitious purpose. That is, flexible wires were connected to electric light mains under the sidewalk—the same as could be done in any city—and led to the safe which was pierced. One wire was connected to the safe and the other having a suitable resistance in circuit was connected to a carbon electrode. The remainder of the operation—that is, the burning of a hole through the safe—is so simple that I have seen persons who have had little or no knowledge of electricity do it with perfect ease almost the very first time.

An electrician who is at all versed in the variations in electric currents of the present day would not be at a loss to skillfully handle his volts and his amperes and that without the necessity of placing the volts in one pot and the amperes in another. Sleuth says "no one can be quite sure of proportions in ordinary commercial currents, and consequently he might err fatally in picking up the wrong conductor." This probably accounts for his claiming to know of parties "taking a large current from the street mains, more than is required to melt through safes, though the parties maintained most perfect silence about it ever after." Finally Sleuth assumes that banks are properly protected against access such as would be gained by the use of the electric current by electrical burglar alarms, and here is where I differ from him most emphatcailly, for the prevailing system of burglar alarm has been beaten several times by experts and I have been told that those who recommend its use have admitted this to be a fact.

I desire here to emphasize a few points. The operation of burning holes through safes by the use of the electric current such as can be drawn from an electric light main or a trolley wire, is a perfectly practical and feasible operation, and it is one which many bankers to my knowledge have investigated. The result is that any safe or vault, no matter how thick, can be readily and quickly pierced, consequently there is no security whatever in safes and vaults by themselves. They must be protected and the most practical and economical method which suggests itself is that of electrical protection. The system now largely in vogue and which Sleuth, as a detective I suppose, refers to, is open for considerable argument which can be easily brought out if he so desires.

SAMUEL RODMAN, JR.,
Late First Lieutenant 2d U. S. Artillery, Electrician and Explosive Expert.
Chicago, Ill., Feb. 12, 1897.

THE INAUGURATION.—General Passenger Agent Scull, of the B. & O. R. R., recently announced that he had secured the concession from the Joint Traffic Association which makes it possible to give a stop-over in Washington on all first-class tickets sold over the B. & O. through that point. The fight over this concession was quite a bitter one and lasted for a long time, but Mr. Scull finally triumphed. In order to successfully handle the great crowds that are expected in Washington during the inauguration of Major McKinley, the B. & O. has arranged to lay about ten miles of additional side track to store sleeping cars and special trains on. The facilities this year will be very much greater than ever before.

LITERATURE

ACCUMULATEURS ELECTRIQUES.—By F. Loppé. Ganthiers-Villars et fils, and Manon & Co. Paris, 1896. pp. 203. 4½ x 7 in. Paper cover. Price 85 cents.

This forms one of the volumes of the "Encyclopaedie Scientifiques des Aide-Memoire." It gives a concise view of the state of the accumulator art at the present day, but makes no pretensions to being as exhaustive as some other works on the same subject.

LA PHOTOGRAPHIE à TRAVERS LES CORPS OPAQUES PAR LES RAYONS ELECTRIQUES, CATHODIQUES ET DE ROENTGEN.—By E. N. Santini, 4th Edition. Charles Mendel. Paris, 1896. 102 pp. 5 x 7 in. Paper cover. Price, 75 cents.

This is a popular treatise on the Röntgen ray, though we hardly think that the author has made the best of his opportunities, considering the abundant material at hand. For those interested in the still obscure manifestation of images of objects produced by lightning flashes the book will perhaps prove of more interest than its principal title implies. The author has gathered a record of the most notable lightning images from the year 360 to 1864. A chapter on psychophotography or the transference of brain images to sensitive plates is also embodied in the work.

A COMPLETE TEST OF MODERN AMERICAN TRANSFORMERS OF MODERATE CAPACITIES.—By A. H. Ford, S. B. Published by the University, Madison, Wis. 1896. 88 pp. 6 x 9 in. Paper cover. Price, 25 cents.

This is a graduation thesis of the most practical kind. The author tested the transformers manufactured by nearly every builder of such apparatus in the United States, the converters varying in capacity from 1,000 to 10,000 watts.

It must be admitted that with one or two exceptions the transformers under test show up remarkably well both as to maximum and as to all-day efficiency. But as the author points out in his conclusions, the results show more than ever the necessity of exercising the greatest care in the selection of the type of transformer. The most notable difference found by the author is in the iron losses. This was to be expected and goes to show once more the necessity for constant vigilance in the testing of such material by manufacturers of transformers.

Another interesting conclusion reached is that the regulation of transformers with the coils arranged so that their cross-section forms a rectangle, is better than it is when the cross-section of the coils is a square.

An introductory note by Prof. D. C. Jackson gives some additional data and calls attention to the important facts that transformers which do not meet the insulation and heating guarantees are unsafe to use, while those which do not meet the iron loss, regulation and exciting current guarantees, waste the company's money.

Incidentally it may be remarked that the tests showed that perhaps as much, if not more improvement is desirable in commercial wattmeters and other measuring instruments, as in the apparatus the latter were employed to test.

The work is the most exhaustive of its kind which has yet come under our notice and every operator of an alternating current station should be familiar with its contents.

ELECTRICITY IN PATERSON. By Wm. M. Brock, 65. pp. 5½ x 8½ cloth.

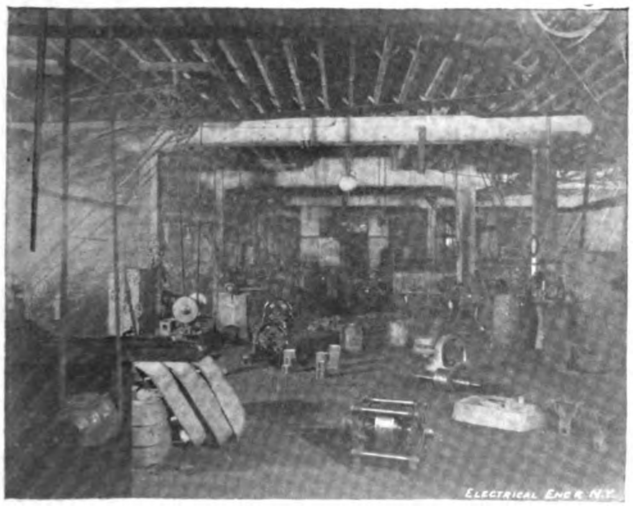
Believing that a better knowledge of the applications and simple laws governing the electric current would be of interest to their customers and further their business, General Manager, Mr. William M. Brock, of the Edison Electric Illuminating Company of Paterson, N. J., has written a book for distribution, in which he has given a concise and clear elementary statement of the A B C of the science. The explanations are ingeniously made by a practical man, and the stereotyped analogies are conspicuous by their absence. An appendix gives a list of electric power users in Paterson, which seems to include practically all work from silk weaving to ice cream freezing. The book is well illustrated, and might with advantage be read by central station managers with a view to the issuance of similar brochures to existing and prospective customers.

NEWS AND NOTES.

THE MANUFACTURING PLANT OF THE TRIUMPH ELECTRIC AND ICE MACHINE COMPANIES.

THE record of the past few years in business can unfortunately show but a small percentage of manufacturing concerns which have been compelled to enlarge their facilities to cope with the demand for their goods, yet such is the fortunate position in which the Triumph Electric and Ice Machine Companies of Cincinnati, O., find themselves. Being cramped in their old quarters, the Electric Company have recently removed to the new and commodious works, some views of which are given in the accompanying engravings. The new works cover a block just opposite the freight depot of one of the principal railroads entering Cincinnati and are so located as to be lighted on the four sides. This site is a remarkably convenient one for factory purposes,shipping facilities are excellent, and reached as it is by six different lines of electric cars, customers and visitors find it readily accessible from any part of the city. A short flight of steps leads directly from the street into the main office, a large, well lighted room, where the visitor comes immediately in contact with the heads of the various departments. From the office the visitor passes into a large wareroom filled with finished material so arranged that prompt shipment of any machine, either motor or generator, of any standard voltage could be made.

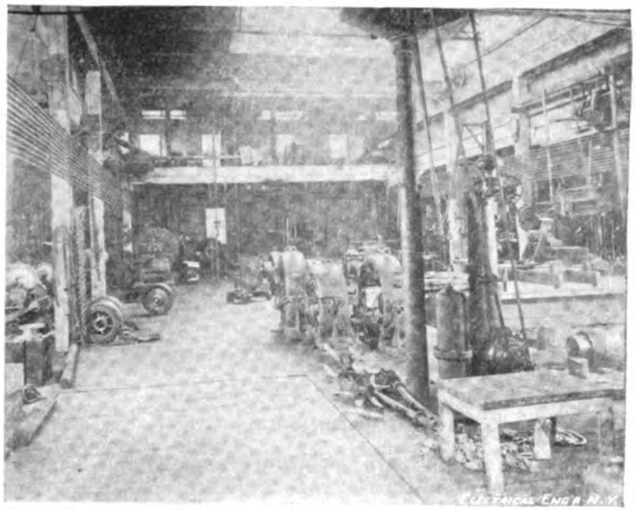
WORKS OF THE TRIUMPH ELECTRIC CO., CINCINNATI, O.



MAIN MACHINE SHOP.

From the wareroom a gangway leads to the main erecting floor, on which electric generators and compressors are in process of erection. At the sides of this room the heavy machine tools are so arranged that they, as well as the main floor, are covered by a traveling crane, which will shortly be equipped with motors. The heavy tools on this floor are arranged in groups, each group driven by a separate motor, which plan the management believes to be the more convenient and efficient in this instance as distinguished from that of a separate motor equipment for each tool.

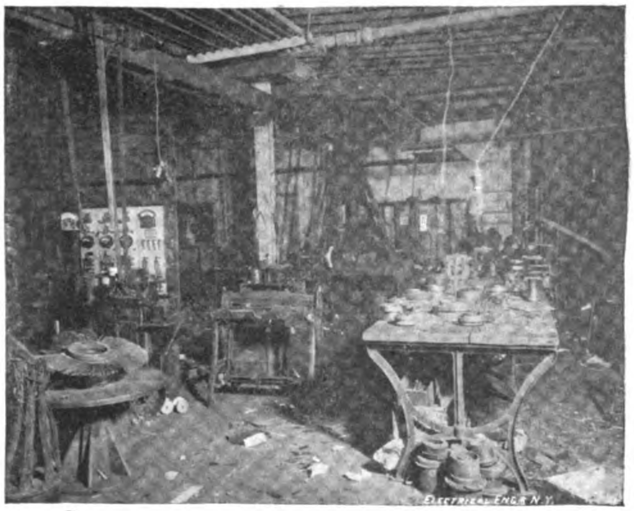
In the rear of the erecting floor is the testing room equipped for the testing of several machines at once, and for any desired load. From the erecting floor one passes to the main machine shop, where again is found the same principle of grouping, with the idea of economical application of electric motors. Here also is located the tool room, itself about thirty-five by forty feet, with rows of shelves filled with special reamers, cutters, gauges, templets and jigs, insuring the economical production of good work and its exact reproduction.



MAIN ERECTING FLOOR AND TEST ROOM.

The small tool department, where are located lathes under fourteen-inch swing, all the turret lathes and screw machines, is a room 40 x 125 and opening from it is the commutator and field winding room 30 x 75.

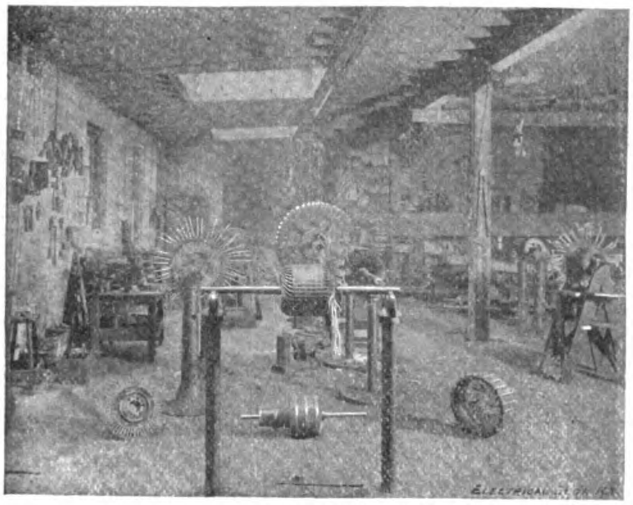
The armature winding room is adjacent and measures 40 x 75. Here one is greatly impressed with the number of special devices apparently in use on each tool, but this is explained by the fact that as far as possible each tool is equipped for its own special work and is seldom changed. An especially noteworthy instance is a group of lathes employed exclusively in the manufacture of the special ice machine fittings, for which this company has an enviable reputation. A rough casting set in one of these lathes is turned out a finished fitting. Great ingenuity is also displayed in the manner of testing these fittings, each one being subjected to severe pressure and with a rapidity that is surprising. One of the especially noteworthy details of the entire equipment is the careful attention given to testing, both in the ice machine and



COMMUTATOR AND FIELD WINDING ROOM.

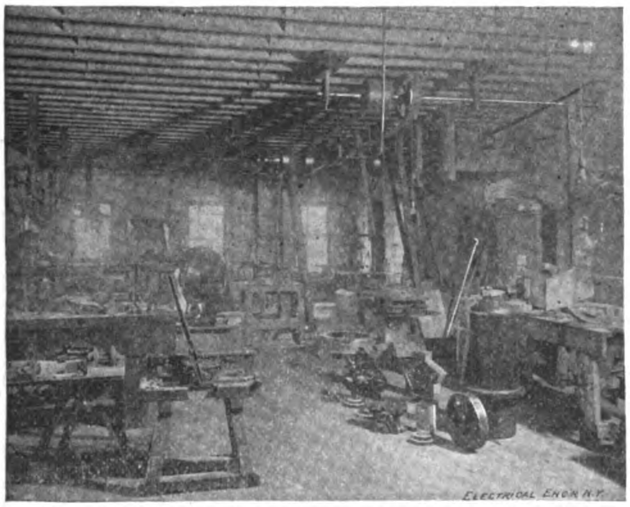
electrical department and the many ingenious devices employed for detecting imperfect material or workmanship. The pipe shop is a room 60 x 125, fully equipped with modern appliances and racks for the storing of the various sized pipe.

The power equipment consists of two high speed 125 horsepower engines driving two generators, one 120 volt, supplying current for lighting and for various motors, and the other a 220 volt, used for test purposes only. The machinery in the pattern shop is driven by a motor hung from the ceiling; the room is 40 x 75 and is adjacent to the draughting room, the best possible location.



The Armature Winding Room.

With the facilities now at their command, the Triumph Electric Company are able to turn out the best quality of apparatus economically, and the busy aspect apparent throughout the worke is evidence of the appreciation of the company's products by their customers.



The Pattern Shop.

TESLA ON LONG LIFE AND SLEEP.

Being asked for his views on reasons and signs of longevity, Mr. Tesla said: "A man receives a certain term of life; so many hours to pass on this earth—I mean hours when he is alive, awake; I do not count the hours when he is sleeping; I do not believe they are, strictly speaking, included in his term of life. When a man really lives he is dying hour by hour, but when he sleeps he is accumulating vital forces which will make him go on living. In other words, in measuring out our dole of hours to each one of us, the great timekeeper stops his count while we are sleeping. Therefore, the longer a man sleeps the longer he will remain on earth. Nearly all long-lived people have been great sleepers. When De Lesseps was on the ocean he would sleep twenty hours on a stretch. Gladstone is a great sleeper, and averages twelve hours a day. I can believe that a man who would learn to sleep eighteen hours a day might live 200 years." Mr. Tesla is himself a very poor sleeper.

TELEPHONY AND TELEGRAPHY

COMMERCIAL CABLE FINANCES.

President Mackay, of the Commercial Cable Company, in a letter to the Barings, of London, says of the bonds they have just placed: "Apart from the issue you are now making, the amount outstanding is widely distributed among holders throughout the United States, Canada and Europe, or held by myself; and I undertake to sell none of my holdings under par for two years, except with your consent. In amount the mortgage is limited to $20,000,000 4 per cent. bonds, or the sterling equivalent in 4 per cent. debenture stock, viz. £4,120,000; of this, $15,000,000 have been issued to purchase $15,000,000 Postal Telegraph Cable Company's shares and property, $1,000,000 to pay for additions to the property made last year and to provide for contemplated extensions during 1897, and $4,000,000 to remain in the Commercial Cable Company's treasury for future requirements. The business contributed by these land lines to the Commercial Cable Company has been increasing yearly, and in 1895 amounted to 30 per cent. of the latter's gross earnings. To secure this traffic in perpetuity the Commercial Cable Company decided to buy the Postal Telegraph Cable Company, and the purchase has recently been ratified by the shareholders of both companies. For the past three years (1896 partly estimated) the net earnings of the land lines have been about sufficient to pay 4 per cent. on their purchase price. I believe that these lines will continue to be self-supporting, and that the interest charge for their purchase will form no burden upon the earnings of the ocean cables proper."

TELEPHONY IN NEW YORK.

The City and Suburban Telephone Company of New York has been incorporated, with a capital of $100,000, to operate a telephone system through the State. The company is to operate to and from New York, Albany, Brooklyn, Buffalo, Schenectady, Amsterdan, Fonda, Fort Plain, Little Falls, Utica, Rome, Ogdensburg, Syracuse, Watertown, Oswego, Monticello, Binghamton, Auburn, Elmira, Geneva, Corning, Rochester, Olean, Batavia, Lockport, and various smaller cities and villages. The directors are: Alfred H. Teller, Charles B. Minshall, Charles A. Teller and G. Rowland Munroe, of Brooklyn; Henry B. Oakman and Samuel Bear, of New York City, and Charles E. T. Tomkins, of Jersey City. The company states that it will operate under the patents of the Make & Break (M. & B.) Telephone Co., of Philadelphia, which it has virtually bought. Mr. Oakman is active in the enterprise.

AMERICAN DISTRICT TELEGRAPH SYSTEM.

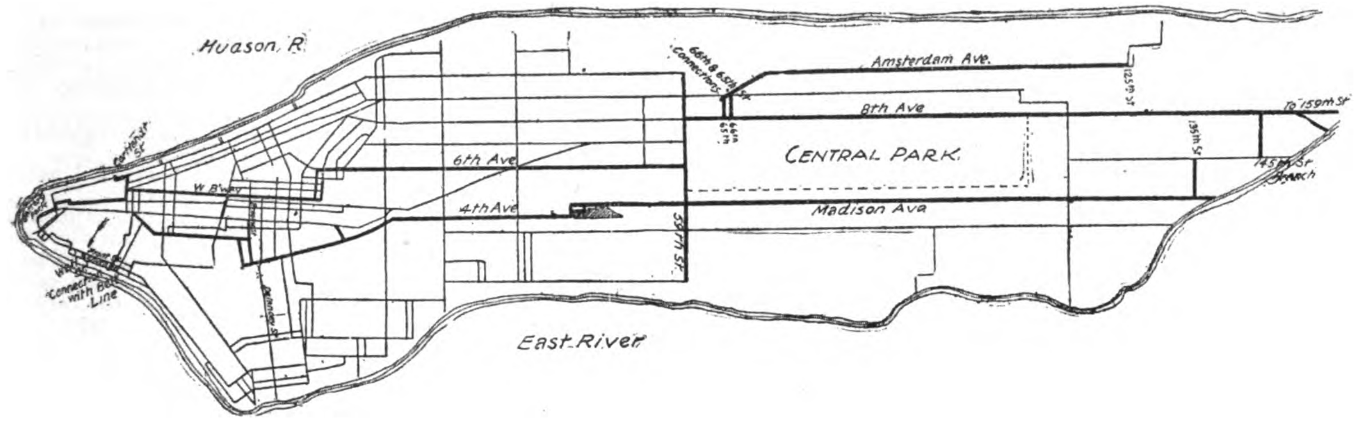
The report of the American District Telegraph Company in New York City for the year ending December 31, 1896, shows a continuation of the business depression which had already been felt for the three years previous. In the report for 1895 it was noted that the old tariff rates had recently been resumed, making a reduction of 25 per cent. in the rates for messenger service, but this is reported to have been already partially recovered by an increase in the volume of business, so that the loss of earnings of the messenger department was about 9 per cent. for the year, while there was an increase in the service performed on messenger calls. The cost of construction and maintenance of lines, rentals of subways, etc., increased 8 per cent. The facilities of the company are reported to be maintained in excellent order, so that it can easily profit by increased business, without any material increase in cost of operation.

CLEVELAND, O.—The Home Telephone Company has made a contract with the New York Construction Company to furnish a complete system of 6,000 telephones within the limits of the city of Cleveland, within eighteen months from January 1, 1897. It will be the Minnis system, described in The Electrical Engineer of July 1, 1895. The company began operating on February 3, and already has its telephone directory out.

ELECTRIC TRANSPORTATION

CONDUIT RAILWAY ROUTES IN NEW YORK.

During the past week the Metropolitan Railway Company applied to the New York State Railroad Commission for permission to change its motive power from horse and cable to electricity, using the underground trolley system, as recently illustrated in The Electrical Engineer. The accompanying engraving shows a map on which the routes to be changed over to electricity are indicated by the heavy lines, together with the extensions to be established between them. The existing street car lines are also indicated in fine lines on the same map. Some slight opposition was developed before the Commission by opposition street railway companies and the hearing on the matter has been postponed until the 10th of March.



Map Showing Route of Proposed Electric Lines of the Metropolitan Traction Co., New York.

ELECTRIC ROADS IN JAPAN.

A leading export house interested in Japanese trade was informed recently that the following street railways were about to complete organization with an aggregate capital of about $3,500,000: The Fushimi Electric Railway, promoted by Okubo Yoskio, of Tokio, will construct a line 28½ miles long, running from Fushimi to Nishinomiya. Another line 5½ miles long between Inamimachi and Demachi. The Tokio Circuit Tramway will build a line 44⅓ miles long in Tokio. All these lines will require, the exporters claim, the necessary materials and rolling stock. American manufacturers will have as much of an opportunity to furnish it as their foreign competitors.

A SCHEME FOR TROLLEY TRACKS FROM MASSACHUSETTS TO THE CANADIAN FRONTIER.

The railroad committee of the New Hampshire House held a hearing last week on bills to incorporate the Manchester, Chester and Haverhill Street Railway, the Nashua, Salem and Haverhill Street Railway, Nashua, Manchester and Concord Electric Railroad Company, and the Merrimac Valley and St. Lawrence Street Railway. These bills cover the scheme to establish a continuous line of electrical railway from the Massachusetts boundary on the south to the Canadian line on the north. The Concord and Montreal and Boston and Maine Railroad Companies and the Concord Street Railroad Company, Manchester Street Railroad Company, Nashua Street Railroad Company, and the Lowell Street Railroad Company opposed the scheme.

SOCIETY & CLUB NOTES

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the Institute held Feb. 17, seventy-five members and guests were present. A paper was read by Mr. John W. Howell on "Conductivity of Incandescent Carbon Filaments and of the Space Surrounding Them." The discussion was participated in by Messrs. Kennelly, Colby, Wolcott, Sheldon, Wirt and Burnett. At the meeting of the Executive Committee in the afternoon the following associate members were elected: Albert W. Brown, assistant manager of Telephone Exchange, American Telephone and Telegraph Company; Alva C. Dinkey, superintendent electric department, Homestead Steel Works, Munhall, Pa.; Budd Frankenfield, instructor in electrical engineering, the University of Wisconsin, Madison, Wis.; Wm. Howe Ripley, student, in department of electrical engineering, Columbia University, New York City; Edward B. Rosa, Professor of Physics, Wesleyan University, Middletown, Conn.; Chris. Van Deventer, student, Columbia University, New York City; Geo. K. Woodworth, electrician, Crawford Manufacturing Company, Hagerstown, Md. The following associate members were transferred to membership: Philip Dawson, associate and chief engineer with R. W. Blackwell, 39 Victoria street, Westminster, London, Eng.; Lucius T. Gibbs, manager and chief engineer, Gibbs Electric Company, Milwaukee, Wis.; Frank J. Sprague, vice-president Sprague Electric Elevator Company, 253 Broadway, New York City; Edward Andrew Leslie, vice-president and manager Manhattan Electric Light Company, Limited, New York City.

MR. K. B. MILLER is to lecture before the Chicago Electrical Association on March 5, upon the subject of "Electrical Resonance."

OBITUARY

EDWIN W. JENNEY.

The death is announced of E. W. Jenney, secretary and treasurer of the Jenney Electric Motor Company, of Indianapolis, of cancerous tumor. Mr. Jenney had been a sufferer from this disease for several months, but only in the last few weeks gave up his work. He leaves a wife and four children. He was associated in the electric company with his two brothers—Charles D. Jenney, president of the company, and Arthur E. Jenney. Mr. Jenneywas born in New Haven, Conn., in 1855. He married Miss Gertrude Smith in Detroit, Mich., and a little later went to Indiana. The Jenneys were a family of electricians. The father, James A Jenney, is still living in Fairhaven, Conn. The deceased was a graduate of Michigan University.

EDUCATIONAL

25th ANNIVERSARY OF THE STEVENS INSTITUTE OF TECHNOLOGY.—THE ELECTRICAL EXHIBITS.

THE celebration of the twenty-fifth anniversary of the Stevens' Institute of Technology, last week, was begun by a banquet at the Hotel Waldorf, in which over three hundred graduates, undergraduates and guests took part. Among the latter were Andrew Carnegie, Abraham S. Hewitt, Commodore G. W. Melville, and J. E. Watkins, of the Smithsonian Institute.

One of the features of the celebration was an exhibition of the work of the graduates of the Institute, which formed quite an extensive collection of apparatus, drawings and photographs which were placed on view in the various laboratories, the machine shop and the library of the Institute. It was noticeable that many of the exhibits of the graduates were of an electrical character, and showed that the excellent course followed in mechanical engineering at the Institute, together with the practice in its electrical laboratory, has eminently fitted the graduates of the Institute to take up electrical work after graduating.

Among the many exhibits of the graduates we noticed that of Mr. John F. Kelly, which consisted of a 40 k. w., 2,000-volt, induction alternator of the type manufactured by the Stanley Electric Manufacturing Company. There was also an original model of a 1 k. w., 500-volt, induction generator, and a 4 h. p., 2-phase alternating motor. On the wall beside the machines were specimens of the Kelly static voltmeters and the static ground detectors, which were illustrated in our issue of last week. The exhibit itself was in charge of Mr. H. L. Fridenberg, also a graduate of the Institute, and now with the Stanley Electric Manufacturing Company.

Close beside this exhibit was that of Mr. L. H. Nash, the designer of the well known Nash gas engine. The exhibit contained a 20 h. p. Nash gas engine direct connected to a Riker 20 h. p. generator, both mounted on the same base. The two were connected by a special flexible clutch coupling, and the current generated fed all the incandescent lamps throughout the shops and buildings during the exhibition. The exhibit was in charge of Mr. C. Baylis, of the Baylis Company.

Mr. H. A. Wagner, in person, presided over the very handsome exhibit of the apparatus designed by him and manufactured by the Wagner Electric Manufacturing Company. This consisted of a 5 h. p., single phase non-synchronous alternating motor, which possessed the excellent characteristic of running at the same speed for which it was designed, in spite of the fact that the voltage obtainable was barely one-half of that for which the motor was designed, the number of alternations being the same, however. There was also shown a 1½ h. p. direct current motor, and various sizes of the Wagner transformers, ranging from 20 to 500 lights' capacity. On a table adjoining the motors and converters were various switches and cut-outs designed by Mr. Wagner, including the high potential non-arcing switch. On the wall adjoining was also shown the alternating current Wagner switchboard voltmeter, with illuminated dial. Added to this was a group of photographs, showing views of additional apparatus and of the shops of the Wagner Electric Manufacturing Company, at St. Louis. Our last issue contained descriptions of much of the admirable apparatus shown.

Mr. H. S. Prentiss, of New York, exhibited his time switch, ally, from the controlling mechanism which releases it, so that intended to cut out lights in show windows, and in other locations at stated periods. The switch is exceedingly simple in construction and the switch is entirely disconnected, electrically, from the controlling mechanism which releases it, so that from the underwriters' standpoint, and also from the standpoint of personal safety, there is no objection to its use in any situation. Mr. Prentiss also exhibited his calendar clock, a marvel of ingenuity and simplicity. The exhibit also contained Mr. Prentiss' synchronizer, a master clock for governing any number of other clocks for general and accurate time distribution.

Mr. J. Van Vleck, consulting engineer for the New York Edison Company, showed a series of photographic views of the steam engineering work of that company, designed by him and carried out under his supervision, and his system of edgewise indicating instruments. Our readers are no doubt familiar with Mr. Van Vleck's work through the description of the New York Edison stations, which appeared in The Electrical Engineer of January 8, 1896.

Mr. A. R. Wolff, of New York, exhibited the complete plans for the steam power, heating and ventilating of the new Astor Hotel, New York.

Mr. W. S. Chester, of the C. & C. Electric Company, exhibited photographs and diagrams of the method of applying electric motors to the driving of organ blowers. A letter of encomium from the celebrated composer and organist, M. Guilmant, formed a part of the very interesting exhibit.

Mr. Joseph Wetzler's exhibit consisted of a set of volumes of The Electrical Engineer, and a copy of "The Electric Motor and Its Applications."

Mr. E. P. Thompson had on view copies of his work on the X-Ray, and the book entitled "The Science of Invention."

Mr. Burhorn, of Burhorn & Granger, exhibited photographs of the power plant of the Dodge Coal Storage System of the Erie Railroad Company, at East Buffalo.

Mr. H. Russell Smith, of Chicago, exhibited illustration and description of a new type of electric elevator designed by him.

Mr. W. D. Pierson exhibited a continuous wire drawing machine designed by him for the Waterbury Machine Company. This machine is designed to draw wire continuously from No. 14 to No. 26 gauge, and from No. 26 to No. 40, with copper or brass. With iron it will draw from No. 18 to No. 30.

In the electrical laboratory was exhibited an electrical laboratory furnace, designed by Mr. W. R. King. This furnace consists of a strip of carbon, placed between heavy carbon terminals, the passage of the current heating up the strip sufficiently to cause the heating of the substances to be decomposed. Mr. King illustrated the action of the furnace by making calcium carbide on a small scale.

Mr. F. E. Jackson exhibited one of the Aylsworth & Jackson celebrated X-ray apparatus and fluoroscopes.

Mr. E. A. Uehling exhibited in operation his useful pyrometer, manufactured by Uehling, Steinbart & Co., and his gas composimeter. The pyrometer measured the temperature of the chimney gases of the Institute's boilers and at the same time the gas composimeter measured the amount of carbonic oxide contained in the chimney gases. The operation of the latter instrument depends upon the absorption of the carbonic oxide by caustic potash, and utilizes in connection with it the same principle as that employed in the pyrometer. This exhibit also contained a specimen of the Steinbart recording gauge, used in connection with both instruments mentioned above.

Mr. E. P. Roberts exhibited drawings of a 2,000 h. p. power house, designed by him for the Lorraine & Cleveland Electric Railway. He also showed plans and photographs and specifications, etc., for other plants installed in municipal and various county institutions, as well as some literature describing the well known Correspondence School conducted by Mr. Roberts, at Cleveland.

Mr. J. W. Lieb, Jr., exhibited a series of views of the pioneer electric light station of the Milan, Italy, Edison Company, of which Mr. Lieb was general manager until recently, when he received a call from the New York Edison Company, of which he is now general manager.

Mr. B. C. Ball showed a steam engine governor and a tachometer, depending upon the stroboscopic effect between the sparks and the spokes of the revolving flywheel; the rate of the vibration of the reed being known, the speed of the engine is also determined when the spokes appear stationary.

Mr. H. M. Brinkerhoff showed photographs and drawings of the intramural and electric elevated railroads.

Mr. John W. Howell, engineer of the Edison Lamp Works, at Harrison, N. J., exhibited a set of incandescent lamps, showing their development from 1880 to 1897.

Mr. H. A. Korneman and W. Strong exhibited dynamos built while students. Mr. F. Uhlenhaut exhibited photographs of the Philadelphia Traction Company's system.

Messrs. R. T. Kingsford & W. H. MacGregor exhibited a continuous steam engine indicator, which gives a separate diagram for each stroke of the engine on a continuous strip of paper.

Among the exhibits of the faculty of the Institute was that of Prof. Alfred M. Mayer. He showed his classical experiments illustrating how a series of floating magnetic needles arrange themselves in regular geometrical figures under the influence of a magnet suspended above them. Prof. Mayer also exhibited some wonderful examples of the floating upon water of polished metals, such as rings. A ring one millimetre in diameter floated, though sunk to a depth of nearly five times its diameter below the surface, the surface tension of the water, of course, keeping it afloat. The influence of vapor on this suspending power was shown by Prof. Mayer. When a ring was floating, the mere opening of a bottle of ether above the water and the coming in contact of the ether vapor with the water surface so reduced the surface tension of the latter that the ring sank immediately. Prof. Mayer also exhibited a series of photographs of the magnetic lines of force made with iron filings, which first appeared in the Franklin Institute Journal in 1871. A number of acoustic apparatus and experiments were also shown by Prof. Mayer, including his topophone for locating the position of fog horns in foggy weather, and his sound mill consisting of a series of acoustic resonators, mounted so as to revolve when placed beside a vibrating tuning fork.

Prof. W. H. Bristol and Mr. B. B. Bristol exhibited a complete line of the Bristol recording pressure gauges, ammeters, voltmeters, etc., which are now so familiar an object in many electric light plants. The exhibit also contained specimens of all sizes of the Bristol steel belt lacings; and views of the factory of the Bristol Company, at Waterbury, Conn., adorned the walls. These photographs were also the work of Prof. Bristol, who is an expert photographer. The exhibit was in charge of Mr. B. B. Bristol.

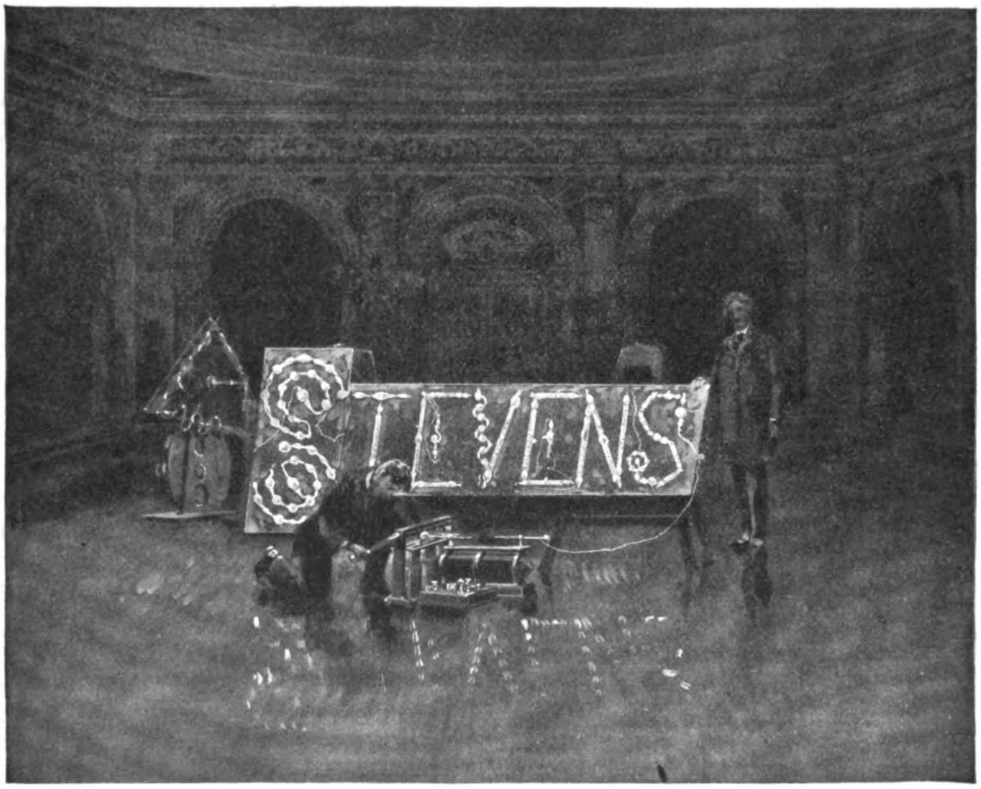
Prof. J. B. Webb exhibited a disc dynamometer, adapted especially for absorbing power at high speeds. This ingenious dynamometer consists merely of a disc running in water, placed within a casing coming close to the sides of the disc. This dynamometer applied to a Curtiss turbine with a disc about 3 inches in water absorbed 180 h. p. at 2,500 revolutions per minute, and about 60 h. p. with 1 inch depth of water. In the apparatus exhibited the disc was driven by a Crocker-Wheeler motor, and the torsion measured by a pointer passing over a scale.

STEVENS INSTITUTE LECTURES IN 1871.

IN connection with the celebration of the 25th anniversary of the Stevens Institute of Technology, which took place last week, there is in course of preparation an illustrated volume which will contain among other things a history of the Institute during its quarter century of existence. One of the illustrations already prepared we give herewith.

It shows one of the experiments used at a lecture given twenty-five years ago, soon after the opening of the Institute, in which a large number of Geissler tubes of unusual size and brightness made by Alvergniat, of Paris (then one of the most prominent manufacturers of these tubes), were arranged to form the word "Stevens" and were illuminated by means of an induction coil built for President Morton of the Institute by E. N. Ritchie, of Boston, and the largest of its kind constructed up to that date. It readily yielded sparks in the air of 21 inches and penetrated blocks of glass 3 inches in thickness. A detailed description of this coil is found in Du Moncel's large work on The Applications of Electricity, vol. II., p. 253; in the Journal of the Franklin Institute for 1871, vol. 61, p. 213 and elsewhere.

In the experiment shown in the accompanying illustration the various Geissler tubes were illuminated with different colors depending upon the nature of the residual gas left in them when exhausted, the material of the tubes,—as when they were made of canary glass which yielded a brilliant green light by fluorescence, or the fluorescent liquids with which the outer tubes or "jackets" of some were filled, as, for example, a solution of quinine sulphate yielding sky blue.



An Experiment with Geissler Tubes of 25 Years Ago.

PERSONAL

MR. H. A. WAGNER, of the Wagner Elec. Mfg. Co., St. Louis, Mo., was a visitor to New York last week in order to attend the Stevens Institute celebrations. An exhibit of his work was a feature of the display of what the Stevens men have done in various lines.

MR. RALPH B. COLEMAN, of Middletown, has been appointed electrical engineer of the Manhattan State Hospital, New York City.

MR. S. A. BARTON, so long prominent in Thomson-Houston affairs in the busy and prosperous days of old, is the latest victim to the hard times through the failure of the Chicago Interior Decorating Company, in which he was the heaviest stockholder. His many friends extend their heartiest sympathies.

MR. W. H. FAIRCHILD, for fifteen years cashier at the Western Union telegraph office at New Haven, Conn., has accepted the management of the Postal Telegraph Cable Company's office there, to succeed Mr. A. L. Page, who died recently. Mr. Fairchild will probably remove his family from Manchester, N. H., where he has been identified with the telephone business for the past eight years.

MR. J. T. NICHOLL, general manager of the Chattanooga Company, Limited, has resigned in order to become general manager of the Rochester, N. Y., Electric Railway Company. In Chattanooga, Mr. Nicholl has done a great deal to build up the company's suburban property and develop local rapid transit. He has also been instrumental in carrying to success the Chattanooga Normal University.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

BY MAX OSTERBERG.

Alternating Currents :

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.—By Alfred Hay, B. Sc. In his series of articles the author refers to the advantages of parallel working of alternators, asserting one of the principal advantages to be the ease with which an additional dynamo may be thrown in or out of the circuit. He then considers synchronous working, and explains that successful parallel working of alternators is a very different matter from mere synchronous running. Successful parallel running depends on the ease with which each alternator will immediately take up its share of the load as it is switched into circuit, and with which it will keep in exact step with all the others during the whole of a period.—Lond. "Elec. Eng'r.," Jan. 22, '97.

Biographical :

E. CARL BREITHAUPT.—Obituary notice with portrait. —Can. "Elec. News," Feb., '97.

Central Stations :

ELECTRIC CENTRAL STATIONS VERSUS ISOLATED PLANT.—By R. S. Hale. In reply to an article published showing the advantages of isolated plants, the author gives details of costs which are rarely counted against small installations, thus proving the superiority of central stations over isolated plants. "Eng. Mag.," Feb., '97. For editorial comment, see "Elec. Eng.," Feb. 10, '97.

Dynamos and Motors:

NOTE ON THE RELATION BETWEEN THE SPEED AND EFFICIENCY OF A DYNAMO.—By Arnold G. Hansard, B. A. A graphic solution of this problem which gives the result that the speed which gives the highest efficiency is that which makes the eddy current losses equal to the C^2R losses. The following assumptions are made: (1) Output varies as the speed. (2) C^2R losses at full load are the same for all speeds. (3) Hysteresis and friction losses are proportional to the speed. (4) Eddy current losses are proportional to the square of the speed.—Lond. "Elec.," Jan. 22, '97.

DISEASES OF DYNAMOS AND MOTORS; THEIR SYMPTOMS AND REMEDIES.—By J. C. Lincoln. Simple rules for finding open circuits, short circuits, and grounds.—Sc. Mach., Feb. 1, '97.

NEW DYNAMO FOR THREE-WIRE DISTRIBUTION.—By M. Alimet. After reviewing several methods previously employed that designed by Müller and built by Lahmeyer is described in detail.—Lond. "Elec. Rev.," Jan. 22, '97, from "l'Elect."

Electro-Chemistry:

ALUMINUM MANUFACTURE IN EUROPE.—An exhaustive review of all the leading European establishments taken from "The Mineral Resources of the United States," 1895, by Dr. David T. Day. Reprinted in full in "Jour. Frankl. Inst.," Feb., '97.

Electric Railways :

DETAILS OF TRAMWAYS, AND THEIR WORKING IN ENGLAND.—A return ordered by the House of Commons has just been issued, giving a good many details as to the tramways and their working. This return gives a total of 153 undertakings, 37 of which belong to the local authorities. The total authorized capital is £18,039,704, while £15,195,933 has been expended. The length of line open for traffic is 1,009 miles, worked by 35,621 horses and 568 locomotives, with 4,663 cars. The number of passengers carried in 1896 was 759,466,047, giving gross receipts £4,152,016. The working expenses came to £3,105,511, leaving as net receipts, £1,046,505. These figures are for the United Kingdom. Of the miles opened, 792 are in England and Wales, 96 in Scotland, and 121 in Ireland.—Lond. "Elec. Eng'r." Jan. 22, '97.

THE ELECTRIC RAILWAYS AND TRAMWAYS OF THE UNITED KINGDOM.—A supplement giving details of track, line equipment, rolling stock, and power house equipment of all the electric railways in operation, and all those in progress in Great Britain and Ireland.—Lond. "Elec.," Jan. 22, '97.

Measurement :

CABLE TESTING CARRIAGES FOR THE CITY ELECTRICITY WORKS IN MUNICH.—By F. Uppenborn. A carriage containing all the necessary measuring instruments for the testing of underground cables, built and designed by the author. Line drawings illustrate the arrangement of the instruments.—"Elek. Zeitschr.," Jan. 21, '97.

Miscellaneous :

ELECTRICAL ENGINEERING IN CANADA.—An editorial note stating in most optimistic terms the chances for constructing and operating engineers with rather poor outlook for the mere laboratory expert.—Can. "Elec. News," Feb., '97.

IMPORT DUTIES IN FOREIGN COUNTRIES ON DYNAMO ELECTRIC MACHINERY AND ELECTRIC LAMPS.—A statement showing the rates of import duties leviable on electric machinery and electric lamps in the principal European countries, and India, recently prepared by the English Board of Trade.—Lond. "Elec. Rev.," Jan. 22, '97.

Power Transmission :

THE LOCAL DISTRIBUTION OF ELECTRIC POWER IN WORKSHOPS, ETC.—By Ernest Kilburn Scott. Author explains the methods of control employed by Mr. Leonard, and the method of control introduced by the Niles Tool Works Company, of Hamilton, Ohio, and gives results of efficiency obtained from actual tests.—Lond. "Elec. Eng'r," Jan. 22, '97.

Storage Batteries :

THE ACCUMULATOR OF FAURE AND KING.—The description and illustration of a new electrode which is said to offer a larger exciting surface to be acted upon.—"Elek. Anz.," Jan. 21, '97.

Telephony, Telegraphy, etc:

TELEPHONING IN GERMANY.—Considerable progress has been made lately in long distance telephony, being due principally to the low price charged. A three-minute conversation over the longest distance, about 580 miles, costs 75 cents. The long distance lines are all metallic circuits, the wires varying between 2, 3, 4 and 5 millimetres, according to the distance.—"Eng'g," Jan. 22, '97.

Transformers :

PROTECTIVE DEVICES FOR TRANSFORMERS.—By Herbert C. Wirt. A paper read before the N. W. Elec. Assoc. Jan. 20, '97. The general conclusion which the author arrives at, after investigating a considerable number of accidents to transformers, is that oil should be used for insulation in every case, as he found by experience that no fire was ever started by the primary of the transformer when oil was used as an insulator.—"Elec. World," Jan. 23, '97. "Elec. Rev.," Jan. 27, '97.—Elec. Eng'r, Jan. 23, '97.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED FEBRUARY 16, 1897.

Alarms and Signals :—

SIGNAL. P. G. Feuerstein, Milwaukee, Wis., 577,128. Filed Oct. 26, 1896.

Comprises a clock having its dial provided with hour and minute contacts, the clock hands as electric conductors that travel against the contacts on the dial, a switchboard having contacts wired to the contacts on the dial, electric signal wires, and an electric split plug for connecting switchboard contacts with signal wires.

Batteries, Primary :—

ELECTRICAL BATTERY. E. Burnet, Wigan, Eng., 577,282. Filed Nov. 30, 1895.

A battery or compound cell applicable for a pocket electric lamp.

Connectors, Conduits and Insulators :—

CONDUIT SHEATHING. H. B. Camp, Akron, Ohio, 577,284. Filed Feb. 10, 1896.

A conduit suitably metallically sheathed externally, and having the sheathing composed of an inner section and outer sections embracing the longitudinal edges of the inner sheathing section.

Dynamos and Motors :—

SPACE BLOCK FOR ARMATURES. H. Geisenhoner, Schenectady, N. Y., 577,130. Filed Nov. 20, 1896.

Consists of a main portion of cast metal, having recesses for the projections of the space block, and projections of strips of metal secured to the casting portion.

BINDING BAND FOR ARMATURES. H. G. Reist, Schenectady, N. Y., 577,148. Filed Nov. 18, 1896.

Consists of a number of turns of wire, loops formed at the ends of the band, and means for securing the ends.

Electro-Metallurgy:—

PROCESS OF ELECTRODEPOSITING ALUMINUM. C. G. Collins, Woodsburg, N. Y., 577,186. Filed May 18, 1896.

Consists in passing an electric current successively through a positive solution containing a salt of aluminum, a porous partition, and a negative solution containing potash, phosphate of aluminum and aqua-ammonia.

ELECTRICAL CASTING OF METALS. N. Slawianoff, St. Petersburg, Russia, 577,329. Filed Jan. 29, 1891.

The metal to be cast is made in the shape of a rod which forms the one electrode of a self-regulating arc.

ELECTRIC FURNACE. F. J. Patten, New York, 577,317. Filed Sept. 15, 1896.

Adapted for the manufacture of calcium carbide.

ELECTRIC FURNACE. F. J. Patten, New York, 577,370. Filed Nov. 6, 1896.

An electric arc being established between the electrodes is made to move by magnetic influence from one point to another.

ELECTROMAGNETIC ARC CONTROLLING DEVICE. F. J. Patten, New York, 577,371. Filed Sept. 8, 1896.

Consists in causing the arc in an electric furnace to traverse a magnetic field in which the lines of force are substantially transverse to the direction of the arc, and reversing or alternating either the arc-producing current or the magnetic field.

Electro Therapeutics:

ELECTRICAL ATTACHMENT FOR BARBERS' CHAIRS. N. H. Burger, Benzonia, Mich., 577,233. Filed Oct. 23, 1895.

Means for supplying an induced current to a brush or similar device.

Lamps and Appurtenances:—

INCANDESCENT ELECTRIC LAMP. C. S. Dolley, R. Hawkins and T. M. Lightfoot, Philadelphia, Pa., 577,159. Filed April 22, 1896.

Consists of an incandescent filament compressed between two non-conducting plates, and from between which plates the air has been exhausted.

Miscellaneous:—

ILLUMINATED SIGN. C. Holland, Millis, Mass., 577,033. Filed March 17, 1896.

A holder adapted to be connected with an incandescent lamp, having spring acting jaws, and a single plate held by the jaws.

METHOD OF PRODUCING MOULDS FOR PAPER MAKING MACHINES. H. Sandham, Spokane, Wash., 577,070. Filed Jan. 20, 1896.

Employs electrolysis.

WATER PURIFIER. J. H. Harrison, New York, 577,134. Filed July 21, 1896.

Consists of a voltaic pile placed in a cylindrical casing.

RESONANT ELECTRIC CIRCUIT. J. S. Stone, Boston, Mass., 577,214. Filed Sept. 10, 1896.

Contains inductance resulting from the magnetization of independently magnetized paramagnetic material.

APPARATUS FOR GENERATING AND APPLYING HEAT TO THERMOCOUPLES. H. C. Reagan, Jr., Philadelphia, Pa., 577,270. Filed April 1, 1896.

Comprises a boiler provided with water tubes, fire tubes passing through the latter, a series of thermocouples supported upon the water tubes and means for holding the couples in position.

ELECTRIC GAS LIGHTER. J. T. Armstrong and A. Orling, London, Eng., 577,279. Filed Nov. 19, 1896.

Details of construction.

METHOD OF REPRODUCING PHOTOGRAPHS. N. S. Amstutz, Cleveland, Ohio, 577,373. Filed April 9, 1895.

Consists in forming an image with continuous parallel lines of varying widths, except where they are discontinuous through the inherent composition of the subject and causing variable electrical impulses to be formed through the medium of such lines and a suitable transmitter and then recording such impulses upon another surface.

ELECTRICAL WARP STOP MOTION FOR LOOMS. A. C. Shuttleworth, Philadelphia, Pa., 577,077. Filed April 30, 1894.

Details of construction.

ELECTRIC IGNITER FOR EXPLOSIVE ENGINES. W. F. Davis, Waterloo, Ia., 577,158. Filed Sept. 24, 1896.

Details of construction.

FIRE EXTINGUISHING APPARATUS. H. F. Maxim, Norfolk, Va., 577,307. Filed Aug. 15, 1895.

Details of construction.

Railways and Appliances:—

ELECTRIC CONTROLLER. E. A. Sperry, Cleveland, Ohio, 577,081. Filed Sept. 21, 1896.

The reversing-switch contacts are mounted directly upon the commutating cylinder.

ELECTRIC RAILWAY MOTOR. A. Schmid, Pittsburg, Pa., 577,071. Filed June 4, 1895.

Comprises a motor supported at one side by the axle, a plurality of springs circumferentially arranged around the axle and bearing against it, a bearing for the motor interposed between it and the outer ends of the springs and gearing between the motor armature, the bearing and the axle, whereby all of the parts rotate together.

ELECTRIC BRAKE. E. A. Sperry, Cleveland, Ohio, 577,119. Filed Feb. 19, 1895.

The combination with an electric motor, of an auxiliary field coil, and means for automatically connecting the coil in circuit with the motor when the cource of supply is interrupted.

Regulation:—

MEANS FOR PREVENTING DESTRUCTIVE FIELD MAGNET DISCHARGES. F. Mackintosh, Schenectady, N. Y., 577,141. Filed Oct. 31, 1896.

Comprises an exciter supplying current to the field coils, a dynamo electric machine in circuit therewith, and a switch for interrupting the exciter circuit and causing the motor to act as a generator and supply current to the field coils.

Switches, Cut-Outs, Etc.

ELECTRIC SWITCH. C. D. Jenney, Indianapolis, Ind., 577,037. Filed April 7, 1896.

An automatic locking device whereby a switch may be locked in the "on" or "off" position, and which will unlock and place it in the "off" position when the circuit is broken.

Telephones:—

TELEPHONE SYSTEM. W. W. Dean, St. Louis, Mo., 577,101. Filed Sept. 19, 1896.

Comprises an electrothermal generator at the subscriber's station which is designed to supply current for the microphone.

PARTY LINE TELEPHONE SYSTEM. W. W. Dean, St. Louis, Mo., 577,102. Filed Sept. 19, 1896.

Provides selective signals for eight separate subscribers' stations placed upon a single metallic circuit.

TELEPHONY. W. L. Bradshaw, Cincinnati, Ohio, 577,231. Filed March 30, 1896.

Interior telephone system.

LEGAL NOTES

THE WURTS-HARRINGTON INTERFERENCE ON AUTOMATIC CIRCUIT BREAKERS DECIDED IN FAVOR OF WURTS.

The Court of Appeals of the District of Columbia has reversed the decision of the Acting Commissioner of Patents, in the case of A. J. Wurts and the Westinghouse Company, appellants, vs. W. E. Harrington. The interference related to automatic circuit breakers now largely used in electric railway work and involved the following claim in Wurts' patent, No. 500,456:

"A fixed contact point, a movable conducting part making normal contact therewith; a wire of fusible metal in shunt around said parts, and means whereby the parts are automatically separated on the occurrence of an abnormal current."

The decision of the examiner of interferences was in favor of Wurts, and was affirmed on appeal to the examiners-in-chief, but reversed by the Acting Commissioner, who awarded priority to Harrington. The present decision reverses the latter's decision and awards priority to Wurts.

A DECISION ON HEATER SWITCHES.

On February 15, in the United States Circuit Court, State of New York, at Utica, Judge Coxe handed down a decision in favor of the American Electric Heating Corporation as against the Consolidated Car Heating Company, of Albany. The title of this suit was, "The Dewey Electric Heating Company vs. The Albany Railway Company." The former is owned by the American Electric Heating Corporation and the latter are users of the Consolidated Car Company's heaters. The object of the suit was to prevent the use of a switch in combination with electric heaters for varying the amount of heat in cars as covered by patent No. 464,247, granted to Mark W. Dewey, December 1, 1891, for "Improvement in Electric Heating Apparatus." In granting the decree Judge Coxe says: "The invention consists in combining any desired number of distinct sections each complete in itself, adapted to be connected with the supply conductors in series, in multiple arc, or in multiple series with a switch for controlling these connections and an indicator operated by the movement of the switch to show how the connections stand." . . . "Matters relating merely to form and location are not the essence of the invention." . . . "The defendants' combination operates in substantially the same manner and accomplishes the same result as the combination of the claim."

REPORTS OF COMPANIES

BOSTON EDISON CO.

In his annual report President Rogers of the Edison Electric Illuminating Company of Boston states that there has been no increase in the capital stock during the year, but to provide additional capital for conservative development purposes, the stockholders on Dec. 10, voted to increase the capital stock by an issue of 5,000 shares. During the year $130,000 debenture certificates were converted into stock; there remain of this issue $178,000 now outstanding, the convertible privilege attaching to which expires May 1, 1897. The figures of operation show:

Year Dec. 31.	1896.	1895.	1894.
Earnings	$773,478	$709,002	$628,406
Expenses	498,298	456,301	311,242
Net	$275,180	$252,701	$317,164
Inc. lamps connected	134,381	108,476	100,047
Arc. lamps connected	1,422	901	853
Motors con. (h. p.)	5,354	4,857	4,349

The Boston Edison Company's balance sheet, Dec. 31, compared thus:

ASSETS.		
Dec. 31.	1896.	1895.
Installation	$3,245,074	$2,857,218
License under Edison patents	338,105	338,105
Liverpool wharf estate	225,912	225,912
Cash on hand	31,260	115,574
Stock on hand	49,803	59,394
Notes and accounts receivable	105,894	112,347
Open accounts	15,418	17,702
Total	$4,011,468	$3,706,454
LIABILITIES.		
Capital stock	$3,240,800	$3,110,800
Debenture bonds	178,000	308,000
Trust mortgage bonds	180,000	180,000
Notes and accounts payable	185,389	15,285
Interest and dividends payable	58,494	57,519
Rents	....	817
Reserve for maintenance	120,000	....
Profit and loss	48,785	34,033
Total	$4,011,468	$3,706,454

THE STOCK MARKET

SOME IMPROVEMENT.

But for the war cloud overhanging the spot where the gallant little Greek is pulling the nose of the sick and bloated Turk, general trade and financial conditions would be in much better shape even than they are. But our markets are largely one with those of Europe, and move more or less in sympathy. General trade has been larger and better, railroad returns are good, and in many lines of industry there is a tendency toward old-time activity.

The stock market has been deadly dull. Western Union has been depressed by a revival of the old rumor that the block of B. & O. stock, issued for the Garrett telegraph lines was coming on the market; but it has not come. General Electric has stayed around 34½, although touching 35⅛; and Am. Bell telephone has reached 219.

TRADE NOTES & NOVELTIES

TNE LATEST LAMP "POOL"

With regard to the reports current about the plans which have been carried out for maintaining the price of lamps at 20 cents, etc., Mr. W. T. Uptegraff, of the Westinghouse Electric and Manufacturing Company, said in Pittsburg last week that the Westinghouse Company was in no combination and knew nothing of any such as reported. Under a recent decision of the Supreme Court of the United States, he said, it was decided that the patent on the vacuum principle of the incandescent lamp was the property of the General Electric Company through purchase from Thomas A. Edison, but as some of the terms of the Canadian and British patents had expired, that fact terminated the life of the patents in this country. The effect of the decision gives to the Westinghouse Electric and Manufacturing Company valid patents on several details connected with lamp manufacture, particularly on the carbon filament, and the means of attaching it to the electric wires for use. Until this decision was rendered no royalties were collected by the company on its detail patents, but notice has been served on all manufacturers that, beginning with March 1, royalties will be demanded.

The companies manufacturing under royalty rights, Mr. Uptegraff stated, would want to hold prices steady in order to prevent ruinous competition, but the Westinghouse Company has no relation with any combination. It demands a royalty from all makers using its patents, and at the same time will make lamps on its own account.

We are informed that no attempt has been made to exclude any lamp manufacturers from the pool, and that negotiations are now pending with a dozen of them. Rumors are afloat as to suits against three concerns.

THE MACINTIRE ARC LAMPS.

At the invitation of Mr. G. R. Macintire, of the International Arc Lamp Company, of New York, we visited last Saturday the first installation of his new arc lamps in the new restaurant of J. Kamsler, at 713 Broadway, New York. Besides the good things provided for the inner man, the proprietor has scored a signal success by the method of illumination adopted, which, we may say at once, was specially remarked and received the unanimous praise of all the patrons.

The lighting of the restaurant is effected by six Macintire enclosed arc lamps suspended from ,or, rather attached directly, to the ceiling; and projecting downward not more than 19 inches, of which 3 inches are taken up by the canopy. The bulb enclosing the arc is shaded from below by a regular incandescent lamp shade, while at a distance of 6 inches, a ring of crystal prisms carried from an ornamental brass canopy gives a finished and artistic appearance to the whole. The lamps are run directly off the Edison mains. They take 80 volts and the resistance in circuit with each is mounted on the switchboard, and does not encumber the lamp, as is usually the case. The lamp burns 150 hours. For artistic appearance and small compass, these new Macintire arc lamps exceed anything which has thus far come under our notice, and they constitute a real step forward toward the utilization of the arc light in interior illumination, not only on land, but for marine purposes, for which they are pre-eminently adapted.

CARBON ELECTRODES FOR ELECTROLYSIS.

The importance of a suitable carbon electrode for industrial electrolysis becomes evident with the increasing production by electrolytic methods of either chemicals or metals in this country. Mr. Hugo Reisinger, 38 Beaver street, New York, who is well known to the electrical trade for his "Electra" arc light carbons, has had great success in the introduction of his carbon electrodes, which are used in the electrolytic production of aluminum, copper, chlorate of potash, etc. The carbon electrodes supplied by him are made of pure carbon. They are homogeneous throughout, of the very highest conductivity, and have a very great life. The European factory which Mr. Reisinger represents in this country has the greatest facilities for turning out large quantities of these carbon electrodes, and among others, has a running contract to supply all the carbon electrodes used in the world-renowned aluminum factories at Neuhausen, Switzerland.

THE ELECTRICAL MANUFACTURERS' AND DEALERS PROTECTIVE AGENCY CO., OF CLEVELAND.

A brief review of the methods of the Electrical Manufacturers' and Dealers' Protective Agency Company will no doubt prove interesting reading to our subscribers, and through the courtesy of Mr. C. S. Horner, secretary of the company, we are enabled to present the general outlines and the methods used to protect its members.

"First of all," said the secretary, "while our general offices are located at Cleveland, Ohio, we are by no means confined to a local territory, but includes each and every State in the Union. Where we find an association that covers a local field, we work in perfect harmony and energetic co-operation with them, as this is the most desirable method of securing maximum results for our members."

Each member of the Electrical Manufacturers' and Dealers' Protective Association as he locates an irresponsible debtor reports the fact to the secretary of the company. The association in turn, by means of a weekly bulletin, reports the facts, without comment, to all members of the association, thus preventing other members from becoming involved by the same debtor. The debtor is notified that his name is placed upon the bulletin, and usually makes an effort to have it removed.

The company maintains a legal department which in case of last resort proves effective, but the experience of the association has demonstrated that about 80 per cent. of reported delinquent debtors square their accounts by resortng to the routine methods of the association.

A number of blank forms are used and each member is furnished with them. Every effort is made to secure a quiet settlement in advance. This is for the welfare of the delinquent debtor who is by this means enabled to make arrangements with his creditor and thus avoid being reported to other members of the association. This method is by no means in the nature of a threat, but is done out of fair consideration, so that if a dispute in accounts has been the reason for a delay in settlement it will in this manner develope before the delinquent's name has been bulletined. This friendly co-operation has resulted in settling many accounts already of long standing without the least unfriendliness.

Now let us take up a class of concerns who are doing business on little or no capital, and who conduct it by being able to procure thirty, sixty, ninety days or more time on their purchases, and who when their credit is about exhausted with one supply house resort to another, who are doing business on credit alone, and are unscrupulous in their methods. The only capital such firms have is credit, and when such a concern is reported and the members of the association demand cash for delivery of goods they usually try to re-establish their credit, which, if successful, accomplishes the ends of the Electrical Manufacturers' and Dealers' Protective Agency Company, if not, it sounds the warning to its members promptly.

The general offices occupy spacious quarters in the Society for Savings Building, Cleveland, O., and in an unostentatious work corresponds with that done by the credit protective associations in New York and other cities; with interesting variations.

ADVERTISERS' HINTS

FREDERICK RECKENZAUN, E. E., 44 Pine street, New York, announces that he makes a specialty of storage battery work designing, examining and testing plants for lighting, power, signaling, etc.

WILSON & WINKLER COMPANY, 779 Greenwich street, New York, are doing a good business in repair and construction work, as well as in furnishing dynamo and engine supplies, brushes, oil cups, gauges, etc., and switchboards.

E. J. WARING, 136 Liberty street, New York, advertises the "Daylight" desk lamp for which he claims many valuable points. Circular and price list will be sent to those requesting them.

THE WESTERN ELECTRIC COMPANY, Chicago and New York are headquarters for tools and supplies. They have recently issued an illustrated price list on brushes and type "E" and "Q" knife switches.

THE ELECTRICAL ENGINEERING AND SUPPLY COMPany, Syracuse, are manufacturing a full line of panel and distributing boxes for any number of circuits in two or three-wire systems.

THE STANLEY ELECTRICAL MANUFACTURING COMPANY, Pittsfield, Mass., call attention to the S. K. C. static ground detector. Among the advantages it possesses they mention, it consumes no energy, can be left in circuit continuously, designed for any e. m. f. from 500 to 10,000-volt.

WESTINGHOUSE ELECTRIC & MFG. CO. present a list of plants equipped with their apparatus for the transmission of power. It aggregates over 55,000 h. p.

THE ELECTRIC STORAGE BATTERY COMPANY have recently installed the largest storage battery plant in the world.

THE WESTINGHOUSE MACHINE CO.'S foreign business steadily increases. The Paris agency recently sold four Westinghouse compound engines, aggregating 1,100 h. p., for electric railway service in Russia.

NEW YORK NOTES.

DOW, JONES & CO. issued an announcement last week that they have leased the entire operating plant of the Printing Telegraph News Company, operating the "page ticker," and will henceforth extend the use of this machine for instantaneous delivery of news. The newsslip deliveries will continue as usual to be employed, either with of without the "page ticker." The development is somewhat interesting in Wall Street news gathering. It was the same bureau of information which ten years ago revolutionized the newsslip service by introducing the printed bulletin in place of the old-fashioned tissue manifold.

VICE-PRESIDENT HENRIQUES, of the Brooklyn Bridge trustees, states that the introduction of electric motive power on the Bridge will not only improve the service, but result in a saving of $10,000 a year.

W. C. BALLDA, manager of the Utica, N. Y., Electrical Manufacturing and Supply Company, has closed a contract with the Walcott & Campbell Spinning Company, of New York mills, for a complete modern lighting plant for their new yarn mill. The installation will consist of an 800-light Eddy incandescent dynamo, 45 of the Manhattan 150-hour enclosed arc lamps and 262 Buckeye incandescent lamps, together with switchboard.

LANSINGBURG, N. Y.—At the annual meeting of the local Beacon Electric Company large extensions of the plant were ordered. The company is doing a good business. The officers for 1897 are: J. George Kaelber, of Rochester, president; S. Bolton, Jr., vice-president; A. Hill, secretary; W. M. Lea, treasurer.

WAVERLY, N. Y.—The Waverly Electric Light and Power Company has elected as its officers for 1897 Mr. J. G. Kaelber, president; H. L. Lang, vice-president; A. Will, secretary, and G. Koch, treasurer. The plant furnishes current in Waverly, Sayre and Athens. Extensive improvements have been ordered, and a 2 per cent. dividend was declared.

M. J. MURPHY.—At a meeting of the creditors of T. J. Murphy & Co., New York, manufacturers of switchboards, etc., the assignee was authorized to accept the bid of $4,800 of the Eureka Tempered Copper Works, the successor of the Eureka Tempered Copper Co., North East, Pa. The plant is turned over to them, and includes everything except the bills receivable. Business to be resumed at once.

THE CROUSE-HINDS ELECTRIC COMPANY, 500 East Water street, Syracuse, N. Y., have just been organized to manufacture electric switches, switchboards, panel boards and electric headlights. The organizers are H. B. Crouse and Jesse L. Hinds. Mr. Crouse is a favorably known young man of Syracuse, possessing energy and business tact, while Mr. Hinds is an old-time mechanic and electrical man, having spent over thirty years in the shops of the Brown & Sharp Company and the Davis Sewing Machine Company. Mr. Hinds entered the electrical field in 1889 as one of the organizers of the Electrical Engineering and Supply Company, being elected vice-president and superintendent, which position he has filled up to the present time.

THE NEW YORK STOCK EXCHANGE is after the bucket shops again and will make new arrangements to control quotations.

THE J. L. CHAPIN COMPANY, of New York City, has been formed to make and sell electrical apparatus. A. C. Chapin, M. I. Oakley and R. H. Oakley are interested. The capital is $1,000.

MR. F. B. TORREY is fitting up an extensive factory at Bath, Me., for the general manufacture of trolley wheels, brass goods, electric car fittings, etc., to be in operation early in March. The plant will be a large one and will be run by electric power.

THE BOSSERT ELECTRIC CONSTRUCTION COMPANY of Utica, N. Y., are about to move their extensive plant into larger quarters, on account of the increase in business. Their novel and ingenious sheet steel switch boxes were illustrated and described recently.

TH7 PIONEER ENCLOSED ARC has been selected for the 14-story building recently erected on Broadway and Twelfth street and occupied by the cloak manufacturers, Meyer Jonasson & Co. The lamps have already been installed and the illumination of the building is regarded as simply perfect.

PHŒNIX INTERIOR TELEPHONE COMPANY are now well housed in their new factory occupying the first story building located at 93 Washington street. There Mr. Sutton reports better trade since the first of the new year, and with its now largely increased facilities for manufacturing the Phœnix Interior Telephone Company is fast getting in position to fill very large orders for all kinds of electrical supplies.

NEWARK, N. J.—The Stucky & Heck Electrical Manufacturing Company, Newark, N. J., are busy on electric railway repair work.

VAN NEST, N. Y.—The contract for the steel work in the new building for the Catholic Protectory at Van Nest, N. Y., has been awarded the Berlin Iron Bridge Company, of East Berlin, Conn. This building is two stories high, having a floor supported by steel posts and girders. The roof construction is to be steel trusses supporting slate covering. The building is 60 feet wide and 160 feet long, having projections 60 feet long and about 30 feet wide on either side at the center for the organ loft and gallery. The ceiling of the upper floor or main auditorium will be arched and the gallery erected of light steel work will be much lighter than it would have been had clumsy construction of wood columns and beams been used.

SOUTHERN NOTES.

AUGUSTA, GA. The business of Moore & Edenfield has been formed into the Moore-Edenfield Electric and Manufacturing Company, with G. P. Weltch as treasurer and R. J. Edenfield as general manager. The concern will carry on a general electrical business and make dynamos and motors.

THE WESTINGHOUSE MACHINE COMPANY has sold to the Tennessee Centennial Exposition Company, four Westinghouse compound engines, each 400 horse-power. The engines will be installed in the Exposition Company's power plant.

WESTERN NOTES

THE BULLOCK ELEC. MFG. CO. is the new name of the Card Elec. Motor & Dynamo Co., of Cincinnati, and a certificate of incorporation to that effect has been issued. The change is desirable for many obvious reasons, and the use of Mr. Bullock's name is regarded by the trade as wise, on account of his active and energetic part in its affairs, and the weight that his name carries.

BALL ENGINES.—An electric light plant has lately been placed in the Wauwatosa County Insane Asylum, Wisconsin. The Ball Engine Company, Erie, Pa., furnished the engines. The direct connected engines and dynamos for the Chicago Public Library are now being put in position. The Chicago Edison Company furnish the dynamos and the Ball Engine Company the engines. The plant consists of five direct connected sets, amounting to 900 h. p.

THE KINLOCH TELEPHONE COMPANY, of St. Louis, which started out on its campaign January 8, claims to have already 2,661 five-year contracts, beginning July, 1898. It offers metallic service at $50 a yeear. Eighty-five miles of McRoy's terra cotta conduit have been contracted for and seven miles supplied.

PACKARD LAMPS.—The manufacturers of the Packard lamp have always had the reputation of doing something handsome in the catalogue line, and this reputation has been maintained by the appearance of their catalogue for the season of 1896-1897. This catalogue is a little more pretentious than any of its predecessors, and a goodly number of its pages are devoted to general data on incandescent lamps, and other general information of a very valuable nature. The Electric Appliance Company have prepared a special discount sheet for this catalogue, giving the present market prices on hign grade Packard lamps, so that the catalogue when supplied with this discount sheet makes a complete lamp reference book. It will be sent to the trade on application.

THE WESTERN ELECTRIC FAN MOTOR does its own blowing and claims to be the breeziest on the continent. Its ability as a never ceasing trade wind can be proved now.

AKRON ELECTRICAL MANUFACTURING COMPANY.—At the annual meeting of the stockholders of the Akron-Electrical Manufacturing Company the following directotrs were elected: S. H. Pitkin, L. C. Miles, W. B. Doyle, D. A. Doyle, F. A. Wilcox. A report of last year's business was favorable and showed a good business was done. The outlook for the coming year is equally favorable.

THE CENTRAL ELECTRIC COMPANY has taken the agency for the new Benjamin waterproof socket. This socket, designed by a man of many years' experience in construction work and particularly work pertaining to street railroad operation, is all that its name implies; it is so constructed as to be attached directly to a 7-16 or 9-16 iron armored conduit; has sufficient metal in its shell to stand a great amount of very hard usage, and wherever used has easily proven its superiority.

THE METROPOLITAN ELECTRIC COMPANY of Chicago have been given the Western Agency of the Bernstein lamps, both arc and incandescent. These lamps are among the best sellers on the market, and those not already using them would do well to give them a trial.

NEW ENGLAND NOTES

PARAGON LAMPS.—A very pretty little brochure of their arc lamps has been issued by the Paragon Arc Lamp Company, of Devonshire Building, Boston. It is an enclosed arc of 150 hours; or, in the plain series form, of 15 hours. Different styles are shown. Conover & Goe, Monadnock Building, Chicago, are the Western agents.

HON. GARDINER C. SIMS has resigned his position as treasurer of the Armington & Sims Engine Company, his resignation being accepted, and he will sever his connection with that corporation in a short time.

ATTLEBORO, MASS.—Contracts for the construction of an Odd Fellows Building, at Attleboro, Mass., have been let by the architect, Albert H. Humes, of Pawtucket, R. I. The building will be five stories high and about 70 feet square. The interior construction supporting the floors will be steel girders resting on steel columns. The contract for furnishing and erecting the steel work has been let to the Berlin Iron Bridge Company, of East Berlin, Conn..

PHILADELPHIA NOTES

THE APOLLO IRON AND STEEL COMPANY, Vandergrift, Pa., have ordered a direct connected set for electric lighting. The engine, which is a 150 horse-power vertical compound, built by the Ball Engine Company, Erie, Pa., is direct connected to a 90 kilowatt General Electric alternating machine. This company already has an electric light and power plant, consisting of three 400 horse-power tandem compound engines made by the Ball Engine Company, which are direct connected to Westinghouse generators of 225 kilowatt each.

The Electrical Engineer.

Vol. XXIII MARCH 3, 1897. No. 461.

ELECTRICITY AT THE HEBREW TECHNICAL INSTITUTE, NEW YORK.

BY W. W. KER.

On February 12, Lincoln's Birthday, the fine new building of the Hebrew Technical Institute was formally opened with appropriate exercises. This Institute was founded to give Jewish boys a training to fit them for the mechanic arts. It takes its pupils from the public schools at the age of about thirteen and gives them a three-years' course which enables them to enter manufacturing establishments as advanced apprentices. Due to the close association with tools, such as wood working, metal working, including instrument making, moulding and casting, together with instruction from men who are expert mechanics and have had considerable experience in their respective trades, the students are prepared to earn a livelihood at once upon graduating from the Institute. After ten years of operation, statistics recently gathered show that 75 per cent. of the graduates are still working at the special branches of work which they pursued while at the Institute.

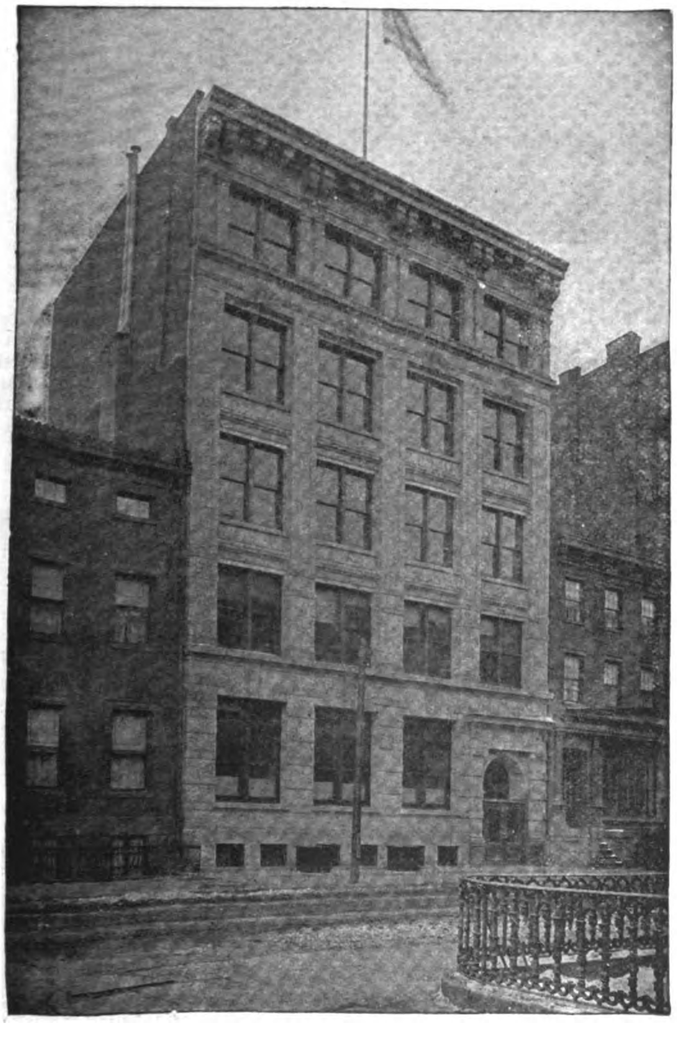

FIG. 1.—THE HEBREW TECHNICAL INSTITUTE, NEW YORK.

The Institute building, illustrated in Fig. 1, is situated at Nos. 34 and 36 Stuyvesant street, is five stories high and built of fireproof material, having a white brick front with sandstone and granite trimmings.

The rooms on each floor are partitioned off with fire and soundproof brick walls and are furnished with modern school fittings. Besides the class rooms used for the English studies, arithmetic and elementary mathematics, there are Junior woodworking, wood carving, Senior pattern making, machine, moulding shops, and drafting rooms.

The electrical laboratory, Fig. 2, is 21x50 feet in size, and is designed to accommodate thirty pupils. The equipment consists of a long bench containing sinks with running water and sewer connections for experiments in chemistry and cleaning and setting up primary and secondary batteries.

At the end of each term the cells are emptied, cleaned and put away. When the new class begins, each pupil is required to set up cells of the most important types, including accumulators, and make measurements of voltage and resistance, and determine the best type of battery for different purposes.

A dark room, containing a slate shelf built on brick brackets is provided for electrical measurements with the Wheatstone bridge and other delicate instruments. This room is also used for photometric and photographic work. The course in electrical measurements is based on the requirements of shop practice, and consists chiefly of tests made with a voltmeter, milli-voltmeter, standard resistances and amperemeter; measurements are also made with a Siemens electro-dynamometer, tangent galvanometer, ballistic galvanometer and standard condensers. The construction and calibration of instruments receive careful attention, and many instruments required in the laboratory are made by the pupils in the shops.

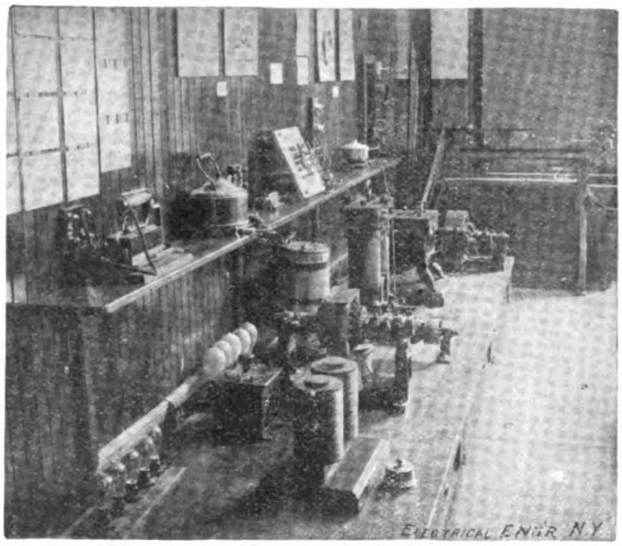

FIG. 3.—DYNAMO AND MOTOR PLATFORM

The two long benches in the center of the room contain sets of apparatus for experiments in static electricity and magnetism for the Junior class work, while the Seniors select their apparatus from the glass cases on the side wall which must be set up and adjusted by them, thus giving valuable practice in preparing for the work which is to follow; for, after all, it is the preparation for a test or measurement which requires the most careful consideration, the actual measurement often being completed by the closing of a circuit.

At the rear of the room, Fig. 3, a heavy yellow pine platform 15 feet long is arranged for holding dynamos and motors for making efficiency tests by the dynamometer method and with the Prony brake. Besides the above machines, which range in size from .5 to 2 kilowatts, there are a number of small models used for making the magnetic calculations of electrical machinery and making tannic acid prints of the magnetic fields of different types. These prints are made by placing a plate of glass on the model dynamo which is made flat, and sprinkling on it iron filings in the usual manner, then moistening a piece of thick white paper with a solution made by dissolving 5 grams of tannic acid in 50 grams of water. The moist side of the paper is then quickly spread over the filings and rubbed with a cloth, which brings the filings in contact with the acid and turns the paper dark, making a lasting print which can be placed in a notebook.

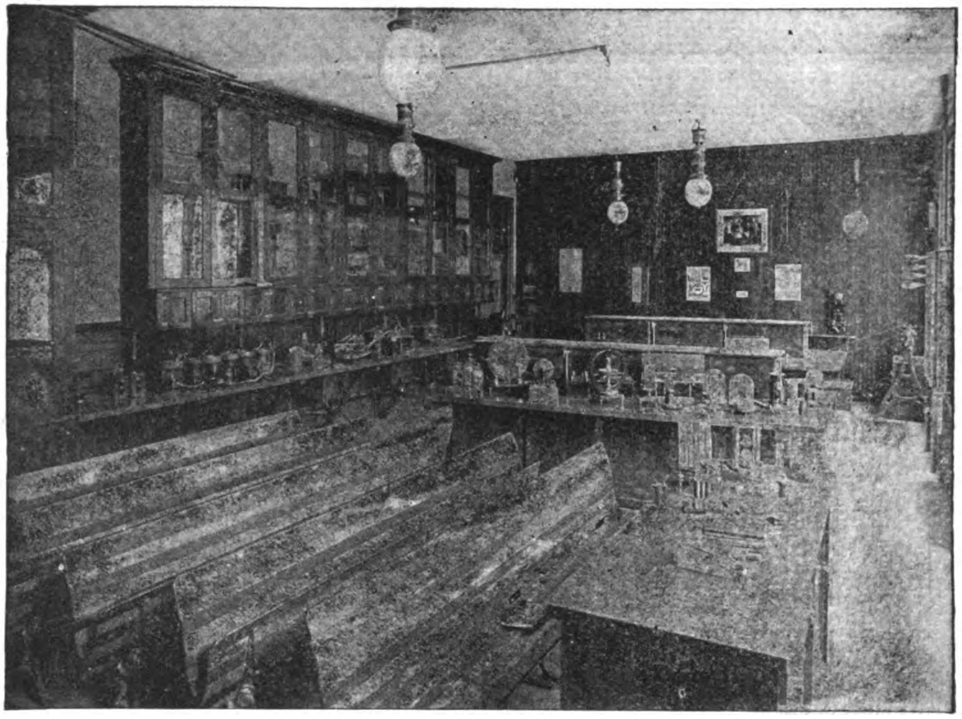

Fig. 2.—The Electrical Laboratory, Hebrew Technical Institute.

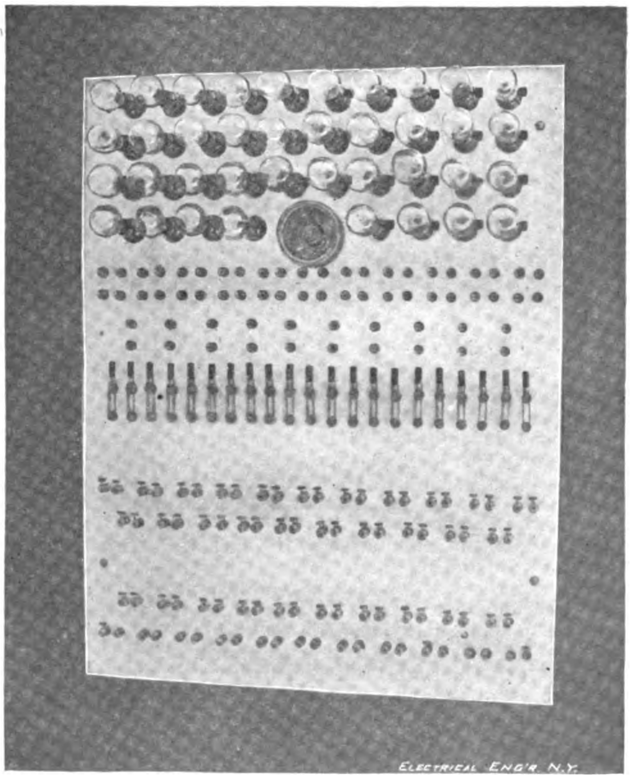

Fig. 4.—Laboratory Switchboard.

Another method tried in the Institute which gives excellent results is to place the magnet under a plate of glass, or, better still, one of porcelain, in order to have a white background; sprinkle the filings as before, and by means of an atomizer spray a thin solution of white shellac dissolved in alcohol over the plate and filings and allow it to harden. The filings will be held to the plate firmly and in their natural position. The shellac, being almost transparent, will give better results than paraffin as usually applied. In Fig. 3 two plates are shown, one of a Weston and the other of the Manchester type of dynamo field, hung on the wall.

Another feature of the laboratory will be a permanent exhibition of electrical appliances and fittings loaned and donated by manufacturing companies, which will be used to assist the pupils in obtaining an idea of their practical operation, method of manufacture, etc. This exhibit is not intended for finely finished models and historical apparatus, but for everyday necessaries used in installation work, from a useful chandelier cut-out bug to the working drawings of an installation.

Fig. 4 shows a white marble switchboard which is the distributing center of twenty-one outlets placed in different parts of the laboratory. It was made by one of the pupils during the past summer and almost any combination of circuits and current regulation can be made in a short time.

The machine shop is shown in Fig. 5.

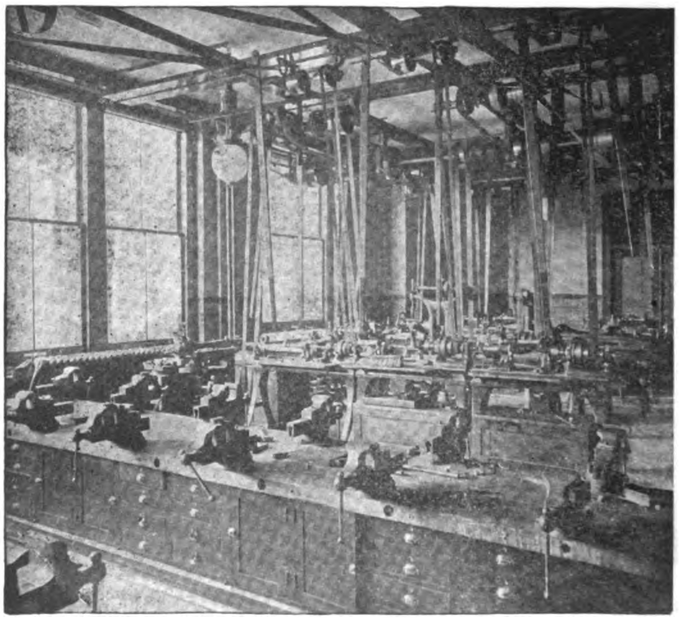

Fig. 5.—The Machine Shop.

The generating plant for the building consists of two 40 horse-power tubular boilers which supply steam to a 60 horse-power Fishkill-Corliss and a 25 horse-power Westinghouse engine. The current is generated by a 25 kilowatt dynamo built by Bréguet, of Paris, and a 20 kilowatt Eddy slow speed multipolar dynamo.

The shops are supplied with power by Eddy motors, and connections are arranged so that power measurements can be made by the pupils.

The machine shop is driven by a 7½ horse-power motor; the Senior pattern shop by a 10 horse-power motor. The Eddy generators and motors were installed by Messrs. H. B. Coho & Co.

The illumination of the shops received careful consideration. On account of the difficulty and expense of having a single 16 candle-power lamp at each machine or work bench, where the filaments are frequently broken and the sockets short circuited by getting tangled in the belts, etc., it was decided to employ arc lamps, and twenty "Pioneer" enclosed arc lamps of the Electric Arc Light Company have been installed. These were placed in position and the machines and benches arranged so as to produce the best lighting effect. As a result the illumination is much superior to that obtained with the old method and the troubles with incandescent lamps have ceased.

The wood-working shops are supplied with the American Electric Heating Company's electric glue heaters, which are under better control than the steam glue heaters, besides being cleaner and occupying less space. Each shop has one two-quart heater which is sufficient for a class of twenty pupils. Three heats can be obtained, the first bringing the cold water to 212 degs. F. in fifteen minutes; the plug switch is then turned to "slow," which provides a temperature of about 190 degs. for the rest of the day.

The building is equipped with a complete system of electric bells which ring in each room at ten minutes and five minutes before the hour and on the even hour, for the changing of classes from one department to another. Each bell has its individual set of batteries so as to avoid annoyances caused by the bells not ringing in some of the rooms as is often the case when a number of bells operated by one push button are connected in series or parallel. All the bell wires have been placed in iron armored tubing to insure their continuous operation. A complete telephone system is in operation using the Franklin movable transmitter.

The entire electrical equipment has been installed with a view to permanence, and extra heavy fittings have been used throughout the building.

THE UNIVERSITY OF NEBRASKA has just had its annual celebration of charter day, and has held its third annual electrical exhibit, in charge of the Society of Electrical Engineers. A large variety of interesting experiments and apparatus were shown in successful operation, reflecting great credit on the students.

ELECTRIC LIGHTING

THE ENCLOSED ARC LIGHT.—VI.

(Concluded.)

BY L. B. MARKS, M. M. E.

REFERENCE has been made to the cutting off of light by the carbon points in the case of short arcs. When cored carbons are used as positives which is generally the case in open arc lamps operated on incandescent circuits, the crater in the upper carbon assumes a distinctly concave formation; the walls of the crater thus cut off a large percentage of light at and slightly below the horizontal, and the interposition of the negative carbon in such cases also decreases the angle subtending the zone of most powerful illumination. The shadows thus thrown by the upper and lower carbon points respectively are distinctly discernible on the globe of the lamp. With the enclosed long-hour arc lamp, in which the carbons are separated from four to six times as much as in the case just alluded to, the concavity of the crater in the upper carbon is inappreciable, and the light is not intercepted by the side walls, not cut off by the negative as in the other case.

I have taken photographs of two lamps, the latter being types of those which are in extensive commercial use in the United States, the one an open lamp, Fig. 11, showing shadows on the globe, the other, the enclosed lamp, Fig. 12, with shadowless globe. The open arc lamp referred to was of the common 10-ampere type, operating at from 40 to 43 volts at the arc, with cored upper carbon 12.7 mm. (½ in.) in diameter, and solid lower carbon 11.11 mm. (7-16 in.) in diameter. The enclosed arc lamp was of the 5-ampere type, operated at from 80 to 85 volts at the arc; solid upper and lower carbons 11.11 mm. in diameter were used. You will note from the photographs that in the open arc the shadows on the globe are very marked, while the enclosed arc globe is shadowless.

In the case of the open arc, especially where cored carbons are used, the crater tends to center itself in the positive carbons. With the enclosed arc, however, the crater tends to wander; instead of issuing from a pointed negative tip located directly below the center of the positive, as is the case with the open arc, the arc stream of the enclosed arc issues from consecutive points along a flat surface, the crater in the positive always tending to be almost directly above the point from which the arc issues. The arc of the crater increases with the current strength; hence the greater the current density, the less marked are the migrations of the arc. When carbons not larger in diameter than about 11 mm. are used in the high potential enclosed arc lamp, the wandering of the arc is not objectionable, especially when the diffusion obtained by the use of the inner bulb is marked. The lamp which I have burning here, Fig. 13, you will note is very steady; the diffusion of light is so perfect that the eye does not detect any motion of the arc.

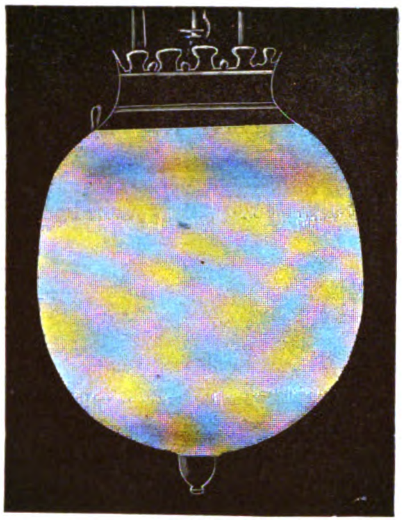

FIG. 11.

Conclusion.—It will be noted that in considering the commercial application of the enclosed arc light, attention has been concentrated on the adaptability of the lamp to direct current constant potential circuits. The introduction of enclosed arcs on circuits of this class has been phenomenally great in the United States during the past year, the open constant potential lamp being gradually relegated to the past. The field for the enclosed arc light, it is believed, will rapidly widen, the application to alternating current circuits being already an accomplished fact, while the adaptation to constant

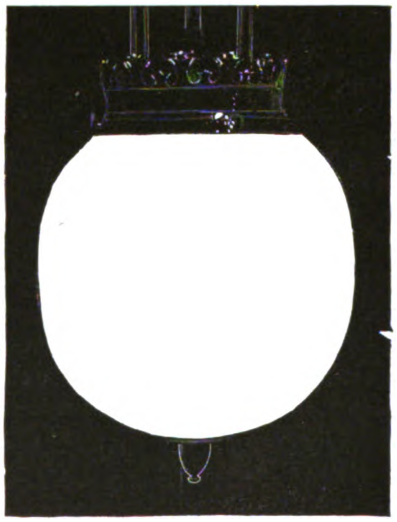

FIG. 12.

current high tension circuits will be simply a question of time.

Summarizing, we may set forth the advantages of the commercial enclosed arc over the open arc as follows: 1. Cost of carbons about one-twentieth of that of the open lamp. 2. Cost of attendance about one-tenth of that of the open lamp. 3. The annoyance of daily trimming no longer an objection to the arc lamp. 4. Absence of shadows of the carbon points; uniform distribution of light. 5. One or more lamps on small amperage, operated independently. 6. Cleanly; carbon dust entirely consumed. 7. Formation and escape of sparks prevented. 8. No flush of current at start or feed. 9. Simple lamp mechanism.

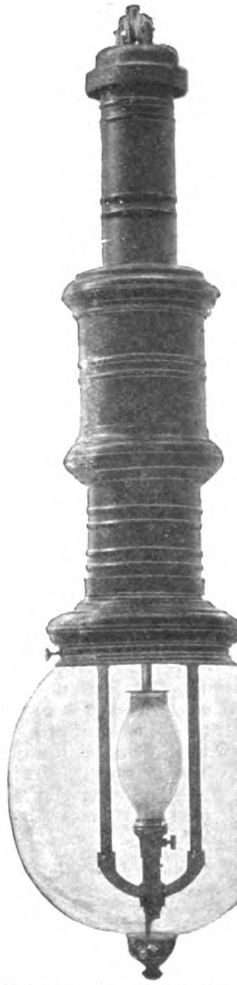

Fig. 13.—Enclosed Arc Lamp for Out-Door Use.

In conclusion I desire most kindly to acknowledge the courtesy of those who have assisted me in the presentation of the subject this evening. I trust this society will also accept my sincere thanks for the honor conferred on me by the invitation to address you on the subject of "The Enclosed Arc Light." Naturally it has been difficult for me to condense the experiences and researches of years into a short address, but I trust that I have thrown at least some light on the subject and opened up the way to further research and development.

CENTRAL STATION COSTS.[1]

In view of the small amount of accurate data obtainable regarding the actual workings of electrical plants, following collection of costs possesses considerable interest and value. The figures were obtained by averaging results obtained for the year included between April 1, 1895, and April 1, 1896, in a large modern Edison lighting plant. The equipment, including water tube boilers, triple expansion vertical engines directly connected to G. E. low tension generators, steam pumps, Wheeler surface condensers and an Edison 3-wire underground distribution, indicates low costs, more than likely below the ordinary run of station. As the costs are given per K. W. hour comparisons can be made with other existing stations.

Costs are as follows per k. w. hour.

Fuel cost per k. w. hour	cents	0.343	
Boiler and engine attendance, including chief engineers and assistants	“	0.281	
Generator and switch board attendance	“	0.058	
Oil, waste and packing	“	0.026	
Water[2]	“	0.002	
Removal of ashes	“	0.025	
Petty miscellaneous expenses	“	0.014	
Generating cost per k. w. hour	cents		0.749
Boiler cleaning and repairs	“	0.049	
Engine repairs	“	0.057	
Dynamo repairs	“	0.007	
Repairs to pumps, steam piping, filters, heaters, condensers, etc	“	0.022	
Repairs to switch board and electrical instruments	“	0.004	
Repairs and care of building	“	0.066	
Total repairs and maintenance of the station per k. w. hour =	cents		0.205
Repairs on customers premises installing of meters and hanging arc lamps	“	0.100	
Including lamp renewals, including lamps furnished for new installations	“	0.257	
Superintendence, maintenance and repairs of underground system	“	0.177	
Carbons, trimmers and repairs of arc lamps	“	0.253	
Reading and repairing meters	“	0.142	
Total distributing expenses	cents		0.929
Total operating, repairs and distributing expenses	cents		1.883
Supply department expenses	“	0.076	
General expenses, including salaries of officers, accounting department, advertising, canvassing, insurance, rentals, taxes, interest and discount, legal expenses, stationery, printing and postage, freight and cartage	“	1.113	1.189
Total cost per k. w. hour	cents		3.072
Interest at 6% on total cost of plant per k. w. hour	“		2.279
	cents		5.351

Kind of coal (soft coal) screenings.
Lamp efficiency, 3.1 watts per c. p.
Engine economy on test 13.45 lbs. steam per I. H. P.
Generator efficiency 92 per cent.

$$\text{Efficiency of station} = \frac{\frac{\text{K W hours}}{.746}}{\text{I.H.P. hours}} = .883$$

$$\text{Efficiency of distribution} = \frac{\text{K. W. hours customers meters}}{\text{K. W. hours switch board}} = .737$$

Of this loss of 26 3-10 per cent., 18 2-10 per cent. is loss by leakage and in current stolen; 8 1-10 per cent. due to drop in C. R.

Of the total output 54 8-10 per cent. was delivered to incandescent lamps, 15 8-10 per cent. to low tension arc lamps and 29 4-10 per cent. to motors.

The percentage of average to connected load was 10 5-10 per cent.

The percentage of maximum to connected load was 32 5-10 per cent.

GAS IN PHILADELPHIA.

Cities and towns tempted to try the experiment of municipal lighting, remarks the Providence "Journal," should investigate the condition of the gas works operated by the city of Philadelphia. The newspapers report that last year's leakage amounted to 1,132,646,138 cubic feet, or nearly one-fourth of the product, and that 40 per cent. of the gas sold was purchased water gas, on which there is a profit of 63 cents a thousand feet. The most curious fact brought out is that the city makes nothing on its coal gas and finds all its profit in handling purchased gas. It is possible, of course, that the exact figures were not obtained, but there is nothing improbable in the story. The best politicians in the country cannot be expected to manage a gas plant as economically as a private corporation can, and it is safe to assume that the legitimate profits of gas or electric lighting concerns will bear less heavily on the taxpayer than the losses due to ignorance and carelessness like that reported from Philadelphia.

The Journal is indebted to Mr. Charles M. Henrotin for this information.

LIGHT: ITS DISTRIBUTION AND DIFFUSION AS RELATED TO QUALITY AND EFFICIENCY.—IV.

(Concluded.)

By E. LEAVENWORTH ELLIOTT.

THE latest attempt of this kind is the globe brought out by Messrs. Blondel and Psaroudaki, of Paris. These globes are provided with horizontal exterior rings and vertical meridianal groovings, the profiles of both being calculated mathematically, according to the laws of optics, so as to give the best distribution, with ample diffusion.

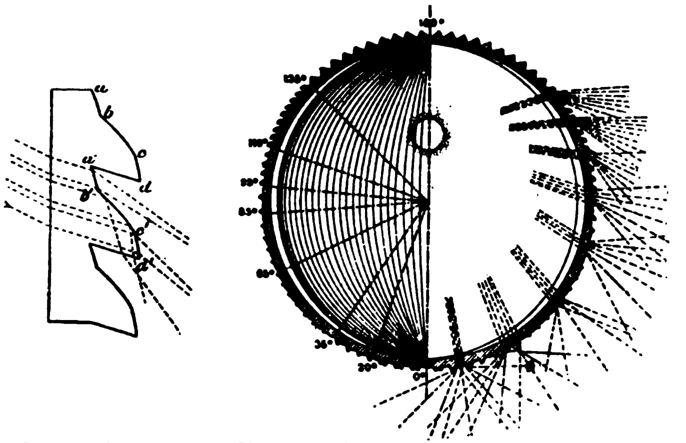

FIG. 2.—MERIDIANAL VERTICAL SECTION OF HOLOPHANE GLOBE.

The two sets of grooves and projection are so formed as to make the entire globe appear luminous, from which fact the inventors have given them the name "holophane," signifying wholly luminous. So ingeniously have the laws of optics been applied to the practical solution of this important problem that a description of the globes will doubtless be of general interest.

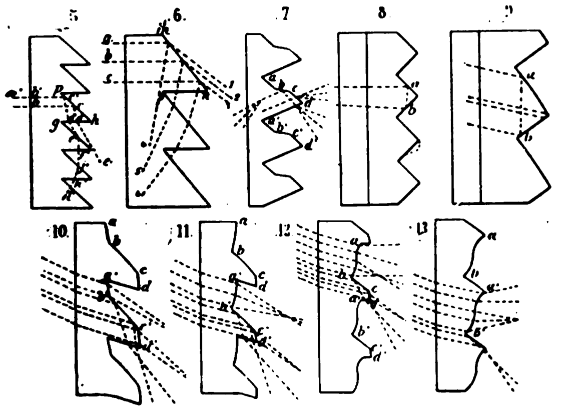

FIG. 3.—VARIOUS FORMS OF PROFILES OF EXTERIOR RINGS, SHOWING REFLECTING AND REFRACTING SURFACES.

The method of designing them is as follows: The general contour of the globe or envelope is first determined, which may be of any desirable form consistent with the process of manufacture. As an example let us suppose that a spherical form is chosen, Fig. 2. The location of the source of light is then decided upon, in this case being generally placed a little above the equator. Since the source of light has more or less surface, it is sufficiently accurate to consider the incident rays on a small section of the surface as parallel, and the surfaces of the section planes. The problem requires that we should deflect each beam in the most advantageous direction, and at the same time spread it out so as to secure diffusion. Theoretically we might accomplish this by giving each section of the

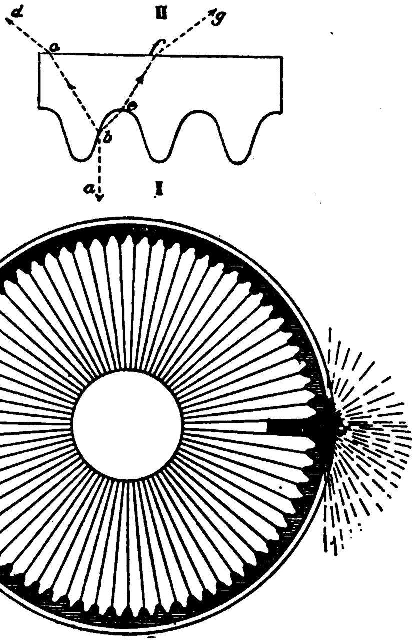

FIG. 4.—I, EQUATORIAL SECTION OF HOLOPHANE GLOBE. II, PORTION OF SECTION ENLARGED, SHOWING FORM OF INTERIOR GROOVES.

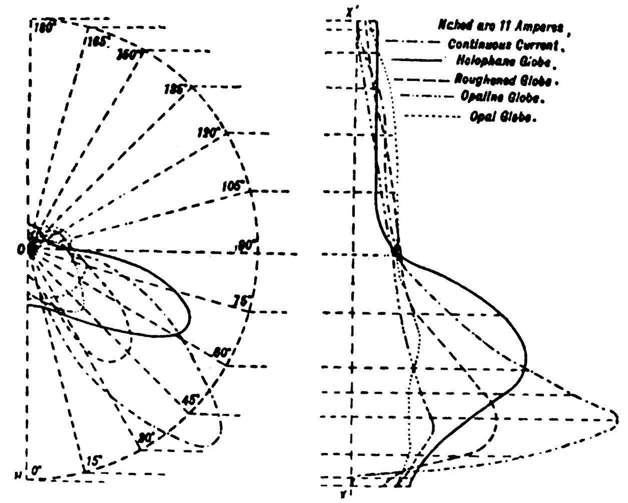

FIG. 5.—CURVES OF DISTRIBUTION AND OF FLUX, OF DIRECT CURRENT ARC, WITH VARIOUS GLOBES.

TABLE I.—Table of Values of the Intensities and Luminous Flux for Different Globes, with the Same Continuous-Current Arc Lamp, Taking 11 Amperes.

	Naked arc.	Holophane globe.	Roughened glass globe.	Opaline globe.	Opal globe.
Maximum intensities in pyrs	2,530	1,640	1,346	773	572
Mean spherical intensities in pyrs	787	692	550	383	434
Mean lower hemispherical intensity (below the horizontal) in pyrs	1,350	1,158	854	578	541
Total luminous flux (lumens)	9,885	8,591	6,968	4,810	5,450
Lower hemispherical flux (lumens)	8,478	7,272	5,363	3,629	2,054
Loss in total flux compared with the naked arc	...	13%	31%	51%	45%
Loss in lower hemispherical flux compared with the naked arc	...	15%	37%	57%	60%

exterior surface a simple, convex or concave profile. But, by such construction a portion of the beam striking the surface at a large angle, would suffer a considerable amount of reflection, the reflected portion being lost in the upper hemisphere. In order to avoid this loss a surface placed at the angle of total reflection b' c' is substituted for a part of the refracting curves. By properly calculating these curves, which is done by the use of mathematical formulæ too long to be given here, the beam may be spread out so as to secure the desired distribution and diffusion, with a minimum of loss. In a similar manner the entire surface of the globe may be divided into such rings, each having its profile so calculated as to distribute the light over the same solid angle, and hence appearing luminous in the line of sight to an eye situated anywhere within the angle. The dividing lines a d between the rings are made as nearly as possible in the direction of the incident rays. Theoretically, each ring should have a different form, due to the different direction of the incident rays; but in practice it is sufficient to divide the periphery into a number of zones, each zone having a special form of ring, as shown at the left side of the section, Fig. 2. Near the top of the globe the rings have the form of doubly reflecting prisms, which deflect the light downward through the lower portion of the globe. Great variety in the profile of the rings is possible. Some characteristic forms are shown in Fig. 3.

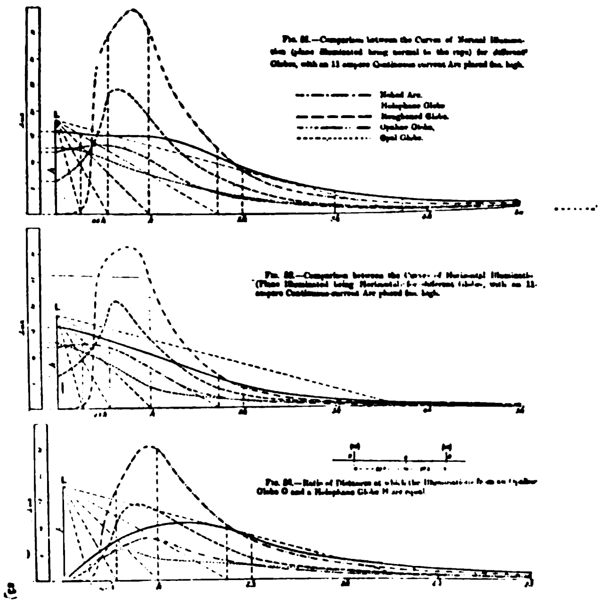

FIG. 6.—CURVES OF ILLUMINATION OF DIRECT-CURRENT ARC. WITH VARIOUS GLOBES.

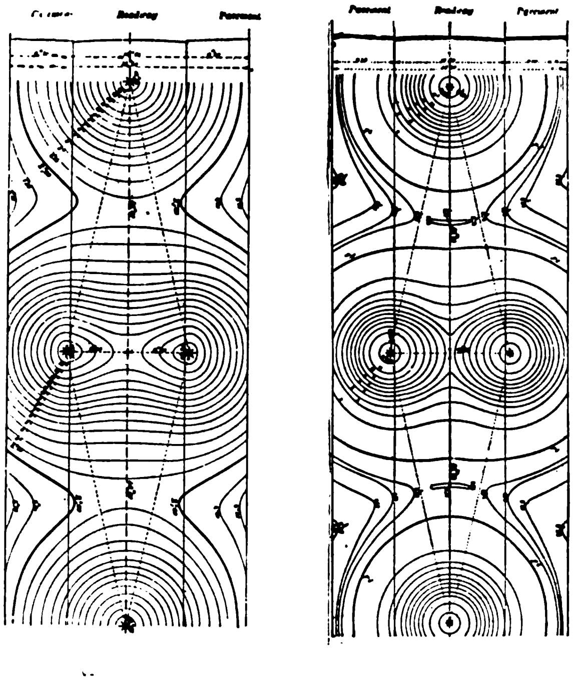
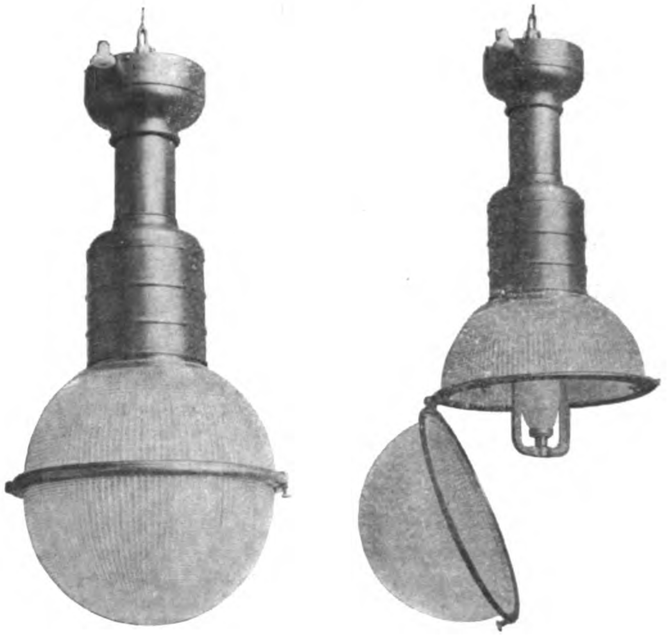


I. II.

FIG. 7.—DISTRIBUTION OF ISOLUX LINES. I., WITH HOLOPHANE GLOBES, II., WITH OPAL GLOBES.

A globe thus constructed with only horizontal groovings or rings will give only vertical spreading, and so appear luminous only in a vertical meridian. To secure lateral spreading of the light, the interior surface is formed of a series of meridianal grooves, from top to bottom, Fig. 4. These grooves all have the same profile since all sources of light give out their rays with practical uniformity in all directions laterally. The curvature of these interior flutings is therefore so calculated as to spread the beam out as nearly as possible over a solid angle of 180 degrees, i. e., tangent to the surface. Furthermore the curve is calculated to distribute the light according to the law of cosines, so that each meridian shall appear equally luminous when viewed from every point. Of the many curves which would fill these conditions theoretically, the one shown has been selected as having the greatest practical advantage.

The effect of diffusing globes is to make the source of light appear larger. If the diffusion is perfect, the entire surface of the globe becomes luminous, as in the case of opal and ground glass. Of all the variously ribbed and corrugated globes made of clear glass, the holophane is the only one which attains this perfection.



FIGS. 8 AND 9.—ENCLOSED ARC LAMP WITH HOLOPHANE GLOBE.

Photometric comparison of the results obtained with the various globes when used with a direct-current arc lamp have been made by Blondel and others, the results of which are very instructive. See table, p. 237.

The results have also been plotted and representative curves are given in Figs. 5, 6 and 7. From these results it will be seen that a better distribution coupled with complete diffusion is secured with much less loss of light by holophanes, than with either ground glass or opal globes.

In conclusion, we may say that the improvements in artificial lighting since the savage first set up his torch, have been chiefly in the direction of producing more intense sources, and more convenient methods of distributing the light units. In economy of production almost no progress has been made. In the improvement of the quality of light, with regard to its physiological effect, we have rather retrograded on the whole. In the means of using the light to best advantage for purposes of general illumination we are yet very far from perfection—in fact, far behind the progress that has been made in the other directions. The great discoveries in light production are yet to be made, viz., light without heat, having practically the same composition as sun light, and emanating from large sources of comparatively low brilliancy.

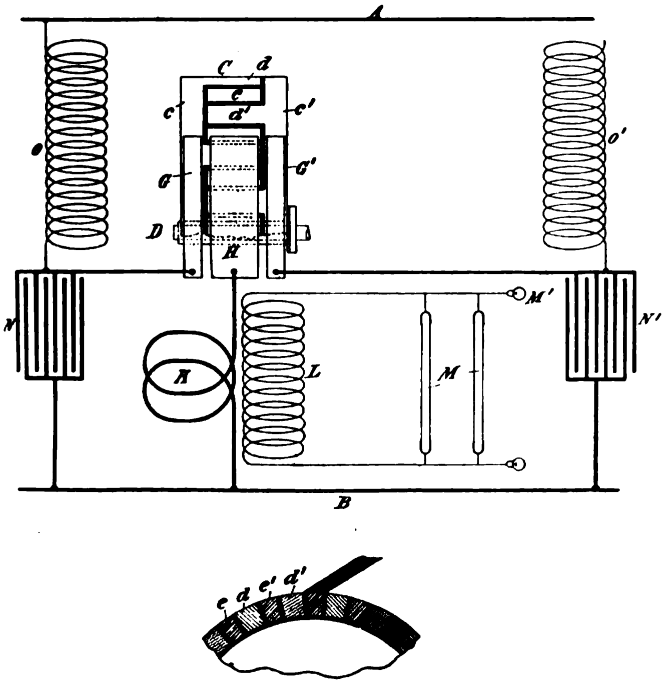
The enclosed arc lamp has been making very rapid strides in popularity of late, and is no doubt destined to play a very important part in interior lighting, and will undoubtedly make a place for itself in exterior lighting, under certain conditions. Its very manifest advantages have been offset to a considerable degree, however, by three disadvantages, viz., 1, waste of current by the use of resistance in series; 2, absorption of light by the opal globes used, and, 3, the discoloration and breakage of the enclosing globes. The first of these difficulties will no doubt be practically removed by the construction of lamps to run two or more in series; and the last two difficulties can be overcome to a large degree by the use of holophane globes. Convenience in trimming is also enhanced by their use, as will be seen from Figs. 8 and 9, which show the method of attaching a 13½-inch holophane to the usual type of enclosed arc lamp, and also the manner of opening the globe for trimming.

A NEW TESLA CONTINUOUS HIGH FREQUENCY GENERATOR.

IN the forms of high frequency generators heretofore devised by Mr. Tesla, and in high potential generators generally, a cessation of flow has naturally been caused during the interruption of the circuit necessary to obtain the "break." In order to produce a continuous high frequency discharge Mr. Tesla has recently designed the apparatus illustrated diagrammatically in the accompanying engravings.

Briefly stated, the apparatus consists in the combination of two condensers with a circuit-controller of such character and so operated by a single motive device as to charge and discharge the condensers alternately, whereby one will be discharging while the other is being charged, and conversely.

The spaces between two adjacent commutator bars d d', Fig. 2, are equal in arc to the width of one of the bars and are filled in with blocks of metal insulated from the other conducting portions of the device. The two heads c c' are insulated from each other. Upon the periphery of this commutator bear three brushes G G' H, the two former resting upon the continuous metallic portions of the two heads, respectively, the latter being in position to bear upon the projections d d' and blocks e alternately.



FIGS. 1 AND 2.

The brush H is connected to the main B through a primary coil K of low self-induction in inductive relation to a secondary L, which constitutes the ultimate source of the current of high frequency which the apparatus is designed to develop. The brushes G G' are connected with the main B through condensers N N', respectively, and to the main A through self-induction or choking coils O O', these latter being used in order that the inductive discharge of the accumulated energy therein may be taken advantage of in charging the condensers.

The operation of the apparatus is as follows: By the rotation of the commutator C the brush H is caused to pass over the projections d, closing the circuits through the primary K and the two cylinders alternately. These two circuits are so adjusted as to have the same capacity, self-induction, and resistance. When this brush is in electrical connection with any projection d' from the part c', the circuit is closed between mains A and B through coil O', brush G', brush H, and coil K. Energy is therefore accumulated in the coil O'. At the same time the condenser N' is short-circuited through the brush G', brush H, and coil K, and discharges through this circuit the energy stored in it, the discharge being in the form of a series of impulses which induce in the secondary L corresponding impulses of high potential. When brush H breaks the circuit through coil O', the high-potential discharge or "kick" from the latter rushes into and recharges the condenser N', but as soon as the brush H has passed over the intervening block e and reached the next segment d it closes the circuit through coil O and short-circuits the condenser N, so that high-frequency currents from either one or the other of the two condensers are flowing through the primary K practically without interruption. Thus without increasing the size or power of the motive device or complicating in any material degree the commutator these devices are made to perform double duty and the output of the apparatus as a whole greatly increased.

It is also evident that all phase differences in the charging and discharging of the condensers may in like manner be seand reached the next segment d it closes the circuit through the same motor and circuit-controller might be made to charge more than two condensers in succession and to discharge them in the same order.

TELEPHONY AND TELEGRAPHY

THE DUSSAUD MICROPHONOGRAPH.

SOME new experiments have been made recently by M. Dussaud relating to the perception of sounds by deaf mutes, by means of an apparatus called the microphonograph. The object of this apparatus is to magnify the voice just as a lens magnifies objects for the eye. The instrument is applicable not only to the magnification of the voice, but has also been shown to be extremely useful in ausculation and the study of the feeble sounds given out by healthy and diseased organs of the body. On the other hand it is destined to render immense benefits to the deaf and to deaf mutes.

The apparatus which is illustrated in Fig. 1 consists of two parts, the register and the repeater. The register consists of a horizontal cylinder driven by clock work. On this cylinder is fixed a wax barrel before which is placed, enclosed in a case about the size of a watch, a number of small electromagnets, which act on the diaphragm, to which is attached the graver, designed to scrape the surface of the wax barrel. In order to register feeble sounds a microphone of a special type is placed in the region of the organ to be studied, and the microphone connected to the register by wires carrying a current from sixty small sulphate of mercury cells. By means of the current the sounds gathered by the microphone are faithfully repeated by the diaphragm of the microphonograph, and inscribed upon the wax by the graver.

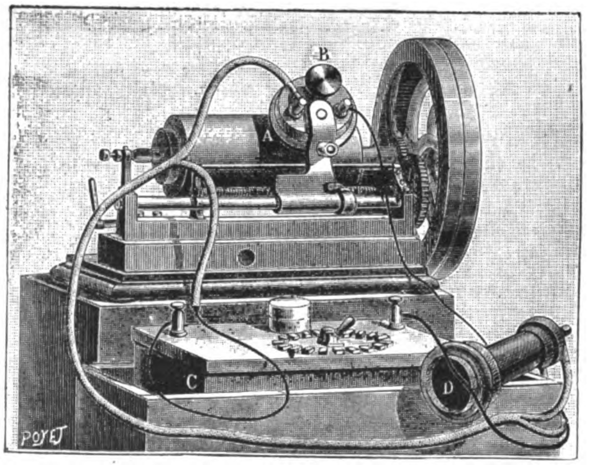


FIG. 1.—THE DUSSAUD MICROPHONOGRAPH.

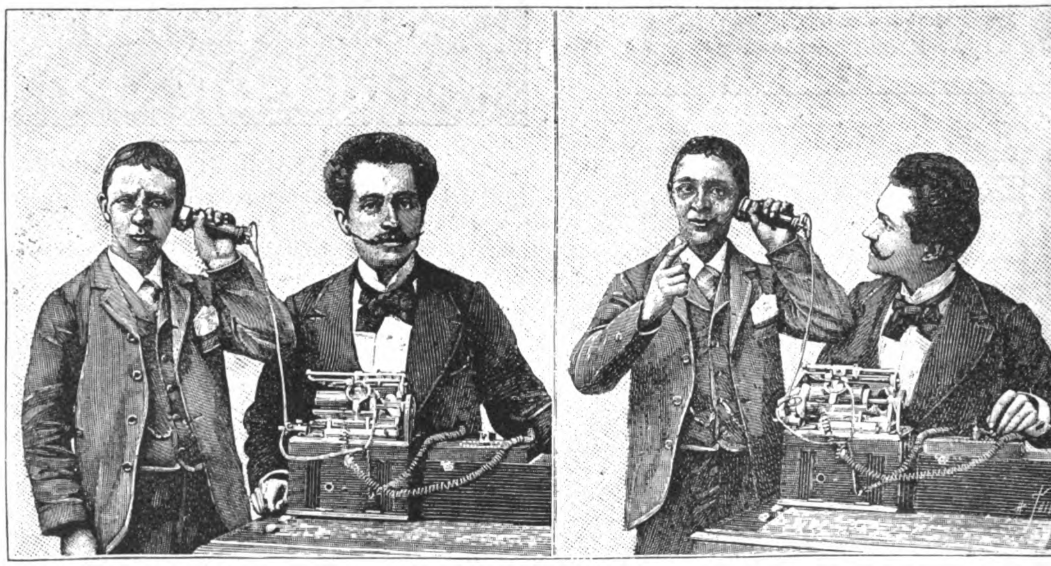
The repeater consists also of a horizontal cylinder operated by clock work. Upon this cylinder is placed the barrel of wax engraved by the register, and in front of it a diaphragm carrying a rounded stylus which fits into the trace made by the graver previously used. Upon the membrane is fixed a small microphone provided with micrometric screws, springs and levers.

When in use the current of from one to sixty cells is passed through the instrument, after which the current goes to a hand telephone. There is then heard the sound inscribed upon the wax, the intensity depending upon the amount of current passing.

Our engraving, Fig. 2, taken from La Nature, shows a young deaf mute listening at the telephone when the apparatus is not in operation, his countenance showing the usual sad appearance. Fig. 3, shows the same lad, taken by instantaneous photography, while the apparatus is playing the Marseillaise. Immediately his face lights up, and instinctively he beats the time. This lad was so deaf that a word shouted into his ear with all possible force could not be heard by him, but as soon as the microphonograph was placed at his ear he manifested his joy, and quitted the instrument with great reluctance. The education of deaf mutes by means of the microphonograph is now being carried on.

The instrument, of course, is admirably adapted to studying the action of the heart. In this direction M. Dussaud has registered the crises due to the emotions of the artist and the orator. In this way one perceives not only the sound but even the movement of the soul; in a word, life itself is registered.



Figs. 2 and 3.—Deaf Mute Listening to Microphonograph Reproduction.

Besides the main object for which it was originally designed the apparatus constitutes an audiometer of the most exact kind; its action depending upon the number of elements necessary to obtain perceptible sounds. Thus one of the young deaf mutes treated by the microphonograph at the beginning of his treatment required twenty-two elements of the battery in order to perceive sound; after ten months' treatment only two elements were necessary, the auditory nerves and auditory apparatus having been so strongly stimulated to activity by the use of the apparatus. M. Dussaud is now at work on a microphonograph of large dimensions, taking considerable current, and intended to make the voice heard by ten thousand persons. This is intended for the Paris Exhibition of 1900.

PROPOSED TELEPHONE LEGISLATION AT ALBANY.

Three or four new telephone bills have already made their appearance, and a new one is presented by Assemblyman Schneider, of Erie. It is provided that in cities of more than 1,000,000 inhabitants telephone companies shall not charge more than $7 per month for each telephone, or $5 a month each for two telephones. In cities of less than 1,000,000 it fixes the toll at $4 per month for each telephone and 15 cents for every 5 minutes' communication between cities or villages less than 50 miles apart and 50 cents between places more than 50 miles apart. A violation of these rates is made a misdemeanor, punishable by a fine of $100.

ROENTGEN RAYS

THE EVOLUTION OF THE X-RAYS.[1]

BY M. CORNU.

THE past year affords a striking example of the outcome of the accumulated efforts of several generations of natural philosophers, whose starting point was modest enough, but whose final results have assumed exceptional importance. I refer to the discovery of Prof. Röntgen, of which I, as a physicist, feel bound to speak to-day; for these famous X-rays have been to the public, as well as to savants, the scientific event of the year. I will relate their history—an instructive one.

To find the first germ we must go back to the middle of the last century. At that period electrical phenomena excited strong interest; the bold comparison of laboratory experiments with the grandiose manifestations in the clouds, the explanation of thunder and lightning, the invention of the lightning conductor by Franklin, had fired the imagination and spread a taste for electrical experiments. Physics had become a fashionable amusement. People of quality did not disdain to attend the lectures of Abbe Nollet, instructor of physics to the Dauphin, and to follow the demonstrations which the expert experimenter reproduced before their own eyes. Some of the engravings of that time give us glimpses of these gatherings. We see the spruce and coquettish abbes of the court, elegant cavaliers and ladies in grande toilette, crowding round strange looking apparatus, and amusing themselves by drawing sparks from the electrical machine or by producing brilliant brush discharges. The experiment of the brush discharge in vacuo was one of the most remarkable because of its scale and splendor. This brilliant effect was obtained in the "electric egg," a transparent glass globe with two metal rods terminating in knobs, between which the electric discharge took place. The spark was first zigzag, like a lightning flash, then spreading out more and more as the vacuum improved, and, finally, when viewed in the dark, filling the entire globe with a magnificent rose-colored or purple glow. Such was the simple and charming experiment which, after having entertained the dilettanti of physics, has now led to those famous rays which are endowed with such curious properties. But the way was a long one.

For nearly a century nothing new was added to our knowledge of this brilliant phenomenon. It was not until 1843 that Abria, of Bordeaux, while making researches in induction, tried to pass the induced discharge across the "electric egg." He found that at a certain exhaustion the beautiful violet glow, diffused all over the interior of the globe, become stratified; that is to say, divided alternately into bright and dark strata. Furthermore, the positive knob always gave a brush discharge, while the negative knob was surrounded by a dark space. It is this dark space which played an important part later. After Abria, the stratified discharge, excited with more powerful electrical apparatus, was studied in England and Germany by Gassiot, Warren de la Rue, Spottiswoode, Hittorf and Crookes, and the shape of the bulb became definitely that of an elongated hour glass, furnished with two electrodes, which replaced the two rods of the "electric egg." Regular stratification becomes apparent at the degree of vacuum cited by Abria, and with the same characteristics, viz., a brush discharge at the positive electrode, and a black sheath round the negative electrode or cathode.

---

[1] Abstract of an address delivered before the French Academy of Sciences.

Needless to say, these experiments were not, as in the last century, simple amusements meant to please the eye. It was hoped by their means to discover the mechanism of the discharge, that is to say, to solve the great problem of the propagation of electricity. But in this respect our hopes were disappointed, and there was a risk that all research in this direction would be abandoned, when Prof. Crookes, guided by theoretical views as to the state of matter in rarefied gases, investigated the behavior of the electric discharge on continuing the rarefaction of the gas in the tube to an extreme degree. He then observed a series of new phenomena. As the vacuum improved, the dark space round the cathode increased in size, driving the stratifications before it, until they vanished one after the other. Finally, the dark space filled the whole tube, the glass of the tube began to fluoresce, especially the part opposite to the cathode. Prof. Crookes saw in this phenomenon the confirmation of his views. He held that it was the molecules of the rarefied gas, repelled by the negative electricity, which bombarded the side of the tube, and that their impact occasioned the glow. He then performed a series of most curious expirements to prove the existence of these projectiles. In one tube he stopped them by means of an internal aluminum screen, and the shadow of the screen was depicted on the end of the tube. In another case he used their impact to turn a little mill. Finally, in a special arrangement, which was afterward termed a focus tube, he directed the convergent fire of this invisible artillery on to a fixed point, an actual focus where refractory bodies, such as rubies and platinum, emitted a brilliant glow.

These brilliant experiments, which Prof. Crookes carried out some twenty years ago, made a great sensation. They were repeated at various meetings, in which many of you have no doubt taken part, and their success recalled the vogue enjoyed a century and a half ago by Abbe Nollet's experimental lessons in physics. But glory is short lived in this world; fashion changes and reputations fade. The Crookes tube soon fell into oblivion, and joined its ancestor, the "electric egg," in the glass showcases of museums. The poor neglected thing meditated for fifteen years on the inconstancy of popular favor, when one fine day it was drawn from its solitude. Hertz, guided by different opinions, took the matter up, and ascertained that the molecular bombardment traversed the aluminum screen, when this latter was not too thick. Physicists, having known for some time that thin layers of silver were opaque to ordinary light, but transparent to ultra-violet rays, saw nothing extraordinary in this. But the phenomenon became interesting from another point of view, when Lenard, making use of this transparency of aluminum, caused the cathode rays, which had until then been confined in a vacuum, to come out from the tube into the air through a small window made of this metal. The radiations, filtered through this remarkable window, excited fluorescence, acted on photographic plates, discharged electrified bodies, and even traversed sheets of black paper. All these properties, which were studied so minutely by Lenard, are precisely those which Röntgen made so famous a few months later. It is only fair to state this, in order not to allow those laborious efforts which are the usual precursors of great discoveries to be hidden from view.

Unfortunately, Lenard's rays apparatus was complex and delicate to handle, and it only gave a small beam of the curious rays. The discovery had, therefore, to be completed by the invention of a more simple apparatus, and, above all, one able to give intense and copious radiation. It was chance, that happy chance which only perspicacious observers know how to profit by, which put into Röntgen's hands the final simple and powerful apparatus. A Crookes tube, inclosed in a cardboard box, was put into action in a dark room, and a fluorescent sheet, which was by chance next to it, glowed. Röntgen noticed this, and immediately concluded that cathode rays from a simple Croopes tube are powerful enough to traverse the glass tube and thick cardboard. Photography through opaque bodies was discovered!

You know the rest. Röntgen soon devised one of the most valuable methods of investigation, to which he drew public attention by means of that somewhat grewsome picture of a transparent hand, of which the bones are visible. Surgery and pathology have been already largely benefited by the new method. Röntgen rays—since they have now received that name—reveal foreign objects in the human body hidden away under the skin, and also show affections of the bones and cartilages. They also enable the diagnosis of pleurisy to be confirmed, as our colleague, M. Bouchard, has recently announced. As the technique becomes perfected the medical applications will become easier and more widespread. Röntgen's discovery has, therefore, been called in to assist in assuaging human ailments. It is another gift to be put to the credit of pure science.

I have already rather tried your patience by speaking of these rays at such length, yet I must add some words about one of their properties which give them considerable theoretical interest. During the last few years much attention has been devoted to the relation between electricity and light. The work of Hertz has proved that electric oscillations can be propagated in air or in vacuo with a speed equal to that of light. Thus electric waves and luminous waves are motions of the same medium. Cathode rays, having the property either of discharging electrified bodies or of themselves assuming a sort of electrical charge which renders them sensible to the action of magnets, add a new link between light and electricity. There is still much which is obscurity, but one feels that physicists are on the eve of making one of those great mechanical syntheses of natural agents, similar to those which we owe to the genius of Fresnel and Ampère.

THE ACTION OF ROENTGEN RAYS ON VISION.

BY FREDERICK S. KOLLE, M. D.

I beg to report that of seven persons with amaurosis, subjected to the Röntgen rays, six observed the Sternschuppenlicht, a peculiar shooting-star light. I have used the German name, as that seems to cover the description or character of the phenomenon. Four of the patients could count the individual stars, ranging between six and thirty-two in number.

The former were not totally blind, that is, they could locate a sixteen-candle-power electric light, with one or both eyes, at variable distances of from three to eight feet. The patient counting thirty-two of these sparklike sensations, using both eyes, could distinguish and locate a lighted lamp at a distance of five feet. The patient who did not respond to the rays had been injured early in life, and both globes had been removed. It is needless to say that none of the patients was enabled to see with the aid of these rays, although by cutting off the rays by the interposition of a steel plate an eighth of an inch thick no such sensation was experienced.

In all of these experiments I used the "radioscope," an instrument devised by me for this work. It consists of the ordinary fluoroscope, with a sheet of aluminum one-twentieth of an inch thick, used in place of the chemical or fluorescent screen; consequently these are not light, but ray effects. I mention this because in all of the recorded experiments the operator obtained considerable if not all light effects by using the bare charged tube, along or in conjunction with the fluoroscope.

From the foregoing I infer that this peculiar sensation depends, as regards its activity, that is, an increase in the number of Schuppen, upon the better or less atrophied or otherwise affected retina. That the lenses are not opaque, or rather impervious, is shown by the same phenomena appearing in the normal eye after a lengthy exposure, attended by headache, supra-orbital, and deep-seated pain in the globes of the eyes.

GOOD READING.

The weekly issue of "The Living Age," bearing date Feb. 13, is the Monthly Supplement number, and including the supplement, contains 96 pages. Among its most striking features are "All Souls' Eve in Lower Brittany," a delightful sketch of the customs and folk-lore of the Breton peasants, translated for "The Living Age" from the French of Anatole le Braz; the first part of "The Land of Suspense," Mrs. Oliphant's latest story of the seen and unseen; a passage from Mrs. Steel's stirring story of the great mutiny, "On the Face of the Waters;" Herbert Spencer on "The Fallacies of Socialism"; a discussion of "Political Ideals and Realties in Spain," by Emilio Castelar, translated for "The Living Age"; and a paper by W. Holman Hunt on "Religion and Art." The "Monthly Supplement," giving Readings from American Magazines, readings from new books, and a list of the books of the month, adds a valuable feature to "The Living Age," which its readers will be quick to appreciate, and with the translations from eminent continental authors, on prominent questions of the day, fairly doubles the value of the magazine which, before these additions were made, was well worth the subscription price of $6.00 a year. The Living Age Company, Boston, are the publishers.

ELECTRICITY FROM CARBON WITHOUT HEAT.

A HUNDRED years ago, when the steam engine had just begun to assume practical form the world looked to the mechanical and steam engineer for the solution of its great economic problems. "I have what every one of your Majesty's subjects desires—power," James Watt is credited with saying. While that dictum is as true to-day as it ever was, the lapse of time has brought about changes which are based on more than sentiment, and which make themselves felt in the ever present demand for power obtained in a manner more economical than that which the steam engine is able to furnish. Indeed, it may be said that the world has turned from the mechanical to the electrical engineer for the solution of what may be well considered the paramount problem in the scientific and engineering world, the production of electric current direct from carbon without heat. The apparently elementary nature of the problem, paradoxical as it may seem, is what constitutes its greatest difficulty, and it may be safely said that the method which shall finally prove successful will, without doubt, be based upon a principle as simple as that of the dynamo machine itself.

Up to the present time the method pursued to accomplish the desired result has been apparently confined to the devising of some form of primary battery embodying electrolytes acting upon the carbon to effect its oxidization. In the most prominent of these which has thus far been brought forward the action of externally applied heat is also employed to facilitate the electro-chemical action; but other methods without this added, and to that extent wasted, application of external heat, have been suggested, none of which, however, has been pushed to any practical limit. An excellent résumé of the subject is that embodied in the admirable lecture delivered by Mr. Willard E. Case at the last meeting of the New York Electrical Society, in which the lecturer gives the essential features of the devices thus far employed to oxydize carbon without heat in the electric battery. Perhaps the most striking suggestion thrown out by Mr. Case was that in which he draws attention to the processes going on within the animal organism by which the carbon is oxydized by the aid of the haemoglobin of the blood, acting as a carrier of the oxygen. The point insisted upon by Mr. Case and the lesson to be drawn from this process of nature is, that the direction in which to work lies in the suitable preparation of the carbon for the oxydizing material to act upon. Of course it may be possible that a simple and inexpensive process may be devised in the future by which this may be accomplished, but it is this very freedom from any antecedent treatment whatever that gives to coal and other natural fuels the strong position which they now hold. It follows, therefore, that the preparatory process which shall give to coal, or other natural products rich in carbon the property of being oxydized at ordinary temperatures, must be essentially inexpensive, if the application of such material is not to be restricted to comparatively isolated situations. Mr. Case's haemoglobin cell was a beautiful illustration of the principle which he evidently desires to impress upon the workers in this field, namely, that the closer they stick to the processes of nature the nearer they come to the desired goal.

ELECTRIC LIGHTING IN NEW ENGLAND.

THE report of the Board of Gas and Electric Light Commissioners of Massachusetts for 1896, for which we are indebted to Chairman Barker, is as usual, an interesting and important document, easily in the first rank for the real information that it discloses as to the condition of a given industry in a chosen part of the country. The powers and work of this board have been so often referred to in our columns, and so recently, that there is no need now to review that matter, the data under notice being that which results from the active supervision of the board in the exercise of its jurisdiction. It will be remembered that an effort is being made in New York State to create a board having like control over these and other interests. The companies generally are not averse to such control, which operates at least as much for their protection as for their restriction, and the main objection here has been the massing of varied and different interests under the one commission. It is assuredly better to maintain separate boards of control, especially if the vigilance exerted is to be so carefully minute as it is in Massachusetts.

It is one of the signs of improvement of the times that the bad showing of the electric lighting plants in Massachusetts in 1895 was changed in 1896 to the right side of the ledger. In 1895 the net result for the industry as a whole was a deficit of $182,248; for 1896, the net surplus is $34,890. Moreover, the dividends paid out had risen from $487,148 to $544,801. But there is plenty of room for further amelioration. Of the sixty-two companies reported on, only thirty-two declared dividends, the average rate being 5½ per cent. Of the other thirty not paying dividends, nine show deficits. It seems to us that this is most distinctly not a condition of affairs to excite envy or inflame the ardor of those who would "municipalize" the plants. Incidentally, it may be noted that the gas companies operating electrical plants showed a profit on that account of $211,154; and there appear to be some twenty-three such systems. The data of the dynamo capacity in service in lamps shows as follows: Six hundred lamps of 10 candle-power, 836 of 15 candle-power, 414,450 of 16 candle-power, 6 of 4,000 candle-power, 12,113 of 2,000 candle-power, 11,522 of 1,200 candle-power, 160 of 1,600 candle-power, 35 of 1,500 candle-power, and 70 of 800 candle-power. The proportion of double carbon lamps runs very high also, owing to their use for street service, but no data is yet included on the subject of the now popular enclosed arc. Turning to electric power, it is very encouraging to note that just about 14,000 horse-power is supplied by the stations, and that no fewer than twenty-seven of them have power circuits. It is curious to observe that only fifty-four motors are running on arc circuits, a condition which now would probably be paralleled all over the country. The city of Boston has about 1,600 motors on the incandescent circuits, and nearly 700 more on power circuits, and all told, some 6,600 horse-power is daily furnished there by means of electricity.

During the year official reports about action on proposed municipal plants were received by the commission from 210 towns and cities. This betrays a lively public interest in the subject, but 179 of them took no definite steps. One such new plant went into operation during the year, and one town started out on the career of doing a commercial lighting business additional to lighting its streets. There are thirteen municipal electric plants now operating in the State. The places that do the least of it have apparently the lowest rates of taxation, though that may mean nothing.

THE WATT.

THE energy with which electrical engineers attacked the problem of determining the various units required in their daily work, and in conforming them to the universal C. G. S. system, is in striking contrast to the tenacity with which the English-speaking nations still adhere to the old, and in many respects cumbersome, mode of designating and calculating power still in vogue. In the course of an admirable address on the watt and the measurement of power, Mr. W. H. Preece, engineer-in-chief and electrician of the British Postal Telegraphs, places at the disposal of the defenders of the decimal system some excellent fighting material. Regarding the origin of the term horse-power, Mr. Preece recalled the fact that Watt's original determination of this unit gave the figure 22,000 foot-pounds per minute, but being desirous of giving his customers full measure he made the horse-power of his engines equal to 33,000 foot-pounds per minute, and thus established a standard which has ever since been followed, though grounded on no physical basis whatever. In order to show how indefinite the term horse-power, in itself is, Mr. Preece quotes Sir Frederick Bramwell as enumerating no less than five different kinds of horse-power, to which Mr. Preece adds another, the electrical horse-power. These include the various kinds of horse-power, such as the gross indicated, the net indicated, the commercial or nominal, etc., and to this must be added the different values given to the horse-power in different countries. Thus in England the horse-power equals 550 foot-pounds per second; in France 542.47, and in Germany 582.25. When we contemplate these facts one is led to believe with Mr. Preece that the term horse-power, like the horse, has probably seen its best days. As a scientific term, it has been much abused, and as a commercial term its meaning is becoming more and more ambiguous. In order to overcome these difficulties Mr. Preece himself in 1881, at the Paris Congress, proposed to designate as a watt 1,000 joules per second, and in 1883 the term was applied by the late Sir William Siemens to the joule per second. The latter proposal has been generally adopted in electrical work, with a result that the power comparable with the horse-power has become the kilowatt instead of the watt, which it would have been had Mr. Preece's proposal been adopted. We are inclined to agree with Mr. Preece in his belief that the acceptance of his proposal would have hastened the departure of the term horse-power.

Apropos of the increasing popularity of the term watt, Mr. Preece mentions the fact that the motormen of the electric cars at Marseilles, France, are called "wattmen," a by no means inapt designation of those controling the power of the car. Electrical engineers find their power calculations so facilitated by the adoption of the watt that the time cannot be far distant when mechanical engineers will follow in their footsteps. We are well aware of the conservativeness and even prejudices existing towards the abandonment by English-speaking nations of the time-honored units based upon the foot and pound, but if for no other reason the demands of commerce and trade with various foreign nations will force the minority to adopt the units of the majority in self defense. Even now some of the most celebrated engine makers in England have changed over their shop system of measurement entirely to the metric. We believe that a few examples of this kind would do more towards bringing about the desired result than any amount of abstract study and theorizing in our schools and colleges. There is another gain pointed out by Mr. Preece in connection with this matter, and that is that names when well selected, secure precision of language; a watt is a watt and nothing else. Every electrical workman knows, or ought to know, what a volt is, and what an ampere is; and as the watt is the product of these two he gets at once, without further effort of the mind, the idea of the quantities he is handling; and he does not have to ask what sort of a watt or kilowatt is meant.

DURING the late political campaign a certain clergyman in the South declared himself so strongly in favor of the McKinley platform that his congregation could not quite stand it, and he found himself out of a job. It is now stated that, when the new administration comes in, he will be "rewarded," with either the ministry to Greece or the headship of the Smithsonian Institution. If this be true, things are a little out of joint. Our sympathy is with the plucky parson, and would be if he had preached a contrary doctrine, for no one likes to see an honest man suffering for conscience sake. But while we have doubts as to the propriety of the ministry to Greece, we have none about the impropriety of the Smithsonian appointment, should it be in contemplation. That demands a special, trained ability, just as the pulpit does, and never more so than now. If the clergyman wants to stay in politics, the Smithsonian is still less for him, and if he wishes to stick to theology, there are many good and proper positions to which he will be welcomed by men who think as he does on financial issues.

THE telephone has been put to many uses, but we have not heard before of its use in suspending the execution of death sentence. This is reported from Georgia, where, with a margin of about one minute, the Governor called up the sheriff and granted a stay of two hours. The condemned man had already been taken to the scaffold and the rope was around his neck. Before the two hours had run out, the Governor telephoned again to the sheriff that he had granted a further respite of eight days. Just what has happened since we don't know, but probably the Governor at this instant is telephoning a suspension of three months. We do not think the telephone was invented to help vacillating Governors make up their minds slowly.

SINCE the appearance of our Municipal Plant data, last week, the town of Gravesend, Long Island, comes forward to furnish the most horrible example yet of waste of municipal funds on commercial enterprises. John Y. McKane, now in Sing Sing, sold a lot of the town common lands while he was in power, and put the proceeds into a municipal electric light plant costing $120,000. Last Wednesday week an offer was made for its poles, for $2,500, and another offer was made of $15,000 for the whole plant. It ought to fetch that, one would think, but the Brooklyn Edison Company, which wants to buy the 673 poles, says that not more than 250 of them are any good. But for the temporary absence of the originator of the enterprise, under circumstances over which he has no control, he would doubtless be furnishing a cogent array of statistics to show how much money Gravesend was saving by the ownership of a plant.

STAMP collectors in Cuba seem to have a hard time of it, especially if hailing from the United States. Mr. G. W. Scott, of the Havana Electric Light Company, has, it would appear, lately been shut up for two weeks, in a small cell, on meager fare, and without communication, on the charge of "having a set of Cuban Republic stamps in his possession." If there is any other charge it has not been made public, while Mr. Scott denies that he had managed to get a set of the stamps, although he may have tried. This little incident in is keeping with many others that excite American indignation, but in all probability there will be no fighting over it. At least it is to be hoped we won't bombard the insurgents on account of it.

MISCELLANEOUS

ELECTRICITY FROM CARBON WITHOUT HEAT.[1]

BY WILLARD E. CASE.

THE subject has such possibilities, all within reasonable bounds, that I hardly know where to commence or finish. At present we have only crossed the boundary line of that field which I am sure will be productive of tremendous results.

Thermoelectricity has attracted attention for a great many years past, and now and then we have heard of new inventions which led us to think that we were about to solve the problem.

As far back as 1801, Ritter noticed that a current was set up when the junctions of dissimilar metals were heated. And following down to a later date, we find that some thermoelectric batteries were constructed which really produced electrical energy at small cost, and which have been to some extent found practicable. A thermocell was described by the speaker before the Royal Society in 1886, which I will now show you. (Experiment shown.)

It consists of plates of tin and platinum, forming the electrodes, immersed in a solution of chromic chloride. When the cell is heated, the electrolyte becomes active: chlorine, leaving the chromic chloride, temporarily combines with the tin and forms proto-chloride of tin. This chemical action generates electricity, and soon the tin is all converted into chloride and the current ceases. When the cell is cooled this temporary combination of the chlorine and tin is broken up and the chlorine returns to chromium proto-chloride. The tin being set free falls as a metallic precipitate to the bottom of the cell in the form of crystals, ready to renew the operation. If this cell works between 80 and 180 degs. F. or 538 and 638 degs. absolute, the e. m. f. at the higher temperature is about .26 volt, but the possible efficiency is less than 16 per cent., owing to the operation of the second law of thermo dynamics, which provides that in the conversion of heat into work, the efficiency equals the higher temperature minus the lower temperature divided by the higher temperature reckoned from an absolute zero, the latter being minus 273 degs. Cent. So that this cell is a heat engine; a reversible voltaic cell which passes through a complete cycle. It must be heated to operate, and cooled to regenerate itself.

In this connection it may interest you to see in operation a more practical thermo cell which converts heat into electrical energy. This battery is said to consume 2½ cubic feet of gas per hour, and to generate 12½ watts. (The Cox thermo generator was shown in operation, driving a fan.)

In order to make the subject clear to those who are not familiar with it, let me say that all electricity (except that produced by water power or galvanic batteries) is obtained from carbon. That is to say, our electric power of to-day is generated by the combustion of coal under the steam boiler, or by means of the gas engine, and through the intermediary of engines and dynamo, this energy is converted into electricity. Now, we all know that this conversion of the potential energy of coal into heat and then into work, is a most wasteful process, owing to the intervention of the second law of thermo dynamics above referred to, and how to overcome this law and to avoid this waste is the subject under discussion tonight. Practically we only convert a small percentage of the potential energy of the coal into work, a large portion being wasted. It is not so much the inefficiency of the boilers or the steam engine or dynamo, which converts this energy into electricity, as it is the method adopted. When we burn coal under the boiler, we transform the energy of that coal into heat energy, and the moment we do this, we come in conflict, or rather become governed by, the second law of thermo dynamics.

It is an inexorable law of nature that under the conditions in which we live, a great waste must accompany the transformation of heat into any other form of energy. To illustrate, in hot air and gas engines, a cold water jacket is usually employed and to raising its temperature is diverted the larger share of the heat. In the thermopile, the junctures must be cooled by a circulation of air or water, and in Edison's pyromagnetic generator, the iron tubes must be cooled by application of cold air.

In accordance with the second law of thermo dynamics, the heat not lost but which we can utilize in a given case equals the difference between the high and low temperatures used, divided by the low temperature. Now, to express this more simply, there is heat, or an expansive force in everything, down to an absolute zero; but under ordinary conditions, we cannot economically use this heat in any machine below the average normal temperature in which we live. So, when once we set up molecular motion, called heat, we only use it above the normal temperature, up to that point to which we are limited by the destruction of matter. Or, as we might say, to that point at which we burn out our boilers or melt our containing vessels. And this range is but a small fraction of the total range of the heat we have produced. Lodge has shown us that the energy in a pint of boiling water, if it could be all utilized, amounts to more than half a million foot pounds, and even if the water were quite cold, and on the point of freezing, it would still contain energy of 350,000 foot pounds of work, or 1-6 of a horse-power hour in every pint. Now, coal or zinc could be burned to heat this water to a boiling point, in which case only a part of the energy between that point and freezing could be utilized, which is a small portion of the total range between the boiling point and absolute zero. But either material can be oxidized in a galvanic battery without heat and waste, and electricity produced. If we burn the coal, as Lodge has suggested, the highest temperature commonly available is that of the furnace; hence the heat should be supplied to the working substance in the cylinder at a furnace temperature. This condition is roughly satisfied in internal combustion engines, though they have many defects at present. This furnace temperature is about 2,000 degrees above absolute zero, or 1,500 degs. Fahr., and if in this engine we could cool down to 600 degrees above zero, or 110 degs. Fahr., we could have a possible efficiency of 70 per cent. of the whole,

$$\frac{2{,}000 - 600}{2{,}000} = .70,$$

that is, 70 per cent., less the friction of the machine and the loss in the conversion into electrical energy, which would bring it down to something like a possible 50 per cent. or 60 per cent. The steam engine does not even approach this. Its theoretical efficiency at 300 pounds steam pressure is 33 per cent., but in actual operation this is reduced to 25 per cent. Gas engines, internal combustion engines come nearer this ideal. In fact, Prof. Thurston states that a cannon when being fired has an efficiency of 50 per cent.[2]

Let it be understood that this is a law of nature; it is inevitable under the conditions in which we live. No cunningly devised furnace or feed-water heater, or cut-off, or triple-expansion apparatus, or pyro-generator can save this heat. The most that any of these devices can do is to save what would otherwise be wasted, over and above that which we must of necessity lose.

Now, the question which we naturally ask is: How are we to convert this potential energy of the carbon into electricity with the least loss?

If the boiler, steam engine and dynamo are not available for our use economically, how shall we do it? We know that the voltaic battery does not act through the transformation of heat into electricity; it produces electrical energy direct. The zinc is oxidized and the potential energy of that zinc is converted directly into electrical energy, without the production of heat. The second law of thermo-dynamics is thus avoided as no heat appears. But, the cost of this zinc and the chemicals employed to oxidize it, are so expensive that we cannot afford to use them. The cheapest materials which present themselves at present to our notice are coal or carbon and the oxygen of the air. And if we could convert the energy of the coal into electrical energy direct and cheaply, we could do away with our steam motors, in time, provided the apparatus was simple and practical. Now, there is no known reason why a cheap substance may not yet be found which will act on coal and develop electrical currents in place of heat, but the general tendency of late, has been to discard this method and to attempt to find some stable electrolyte or bath, which will act as a carrier of the oxygen of the air, conveying it to the carbon and oxidizing it, as zinc is oxidized in a battery, producing electricity. This electrical energy would be the equivalent of the heat energy that would be developed by the combustion of the coal in the ordinary way.

Of course, in the construction of such a cell we must be governed by the experience which we have had with the galvanic battery in which the elements of electromotive force, internal resistance, etc., are involved and by which consequently the output of the cell is governed; such a cell must produce a large amount of energy, be simply and easily cleaned or recharged, in order to be practical. It must be as durable and as simple to use and handle as the steam boiler and dynamo are to-day.

---

[1] A lecture delivered before the N. Y. Electrical Society, Feb. 24.

[2] Science, Oct. 3, 1891.

It may be of interest to give you a comparative illustration of what the energy of coal does to-day, through the use of the steam engine, and what it would do provided we could oxidize it in a battery without heat. The average of large electric light plants, requires 4 pounds of coal for every horse-power hour of electricity delivered from the dynamos to the line. That is to say, four large stations show a consumption of 4.2 lbs. per horse-power hour; 49 stations, 4.6 per horse-power hour; and 32 small stations, 12 pounds per horse-power hour. Theoretically, .175 pound of coal will yield one-horse-power hour, or, allowing for ash, .185 pound, and of zinc, one pound used in a battery produces one horse-power hour under a potential of 2 volts, including the loss in internal resistance. The cubes of these materials represent the weights required by each to produce one electrical horse-power hour. (Experiment shown.)

Of course the subject of electricity direct from carbon has been considered from many points of view. Some have attempted to obtain cheap electricity by using the oxygen of the air to oxidize various substances; others have attempted to oxidize coal with the oxygen of the air without heat, and others have attempted to oxidize coal by the oxygen of the air with the application of external heat. The evolution of this subject is most interesting. We will, therefore, study the question from that point of view, and examine some of the most important batteries which have been constructed. We will do so chronologically. Of course, lack of time will compel me to avoid reference to many well conceived inventions.

Passing over the carbon-consuming cells of Jablochkoff, Bard, Crumm, Edison, Wright and Thompson, I will first describe the cell invented by C. S. Bradley in co-operation with Professor F. B. Crocker, which was mentioned in the discussion of a paper read by the speaker on "Electricity from Carbon Without Heat," in 1888, before the American Institute of Electrical Engineers.

Mr. Bradley described fully the action of fused salts on coal and stated that the oxygen of the air was absolutely necessary for the purpose of cheap oxidation, or, to use his own language: "The cell consisted of fused sodium manganate and putting a blast of air through it and by that means supplying it with oxygen and allowing it to act on the coal which is put in another part of the vessel, a little over one volt was obtained."

The cell consists of an iron vessel 2½ inches in diameter and 6 inches deep, which is placed inside of a retort and heated by a gas flame to nearly a red heat. The electrolyte of the cell is caustic soda, to which peroxide of manganese is added, forming sodium manganate. In this cell is immersed the electrode of carbon which acts as the positive pole, and when the circuit is closed, you will see that we will have an electromotive force of about 1 volt, with a current of 3 amperes. (Experiment shown.)

The next cell to which I will ask your attention is that described by W. W. Jacques in "Harper's New Monthly Magazine" in December, 1896, which is another illustration of the same principle involved in the Bradley cell, with a few practical modifications. It, like the other cell, consists of an iron vessel, which is the negative electrode, containing fused caustic soda, minus the peroxide of manganese, into which is plunged the positive coal or carbon. The oxygen is supplied by a blast of air as in the cell before described, and an e. m. f. of about 1 volt is said to be obtained. The difference between these two cells, which I particularly desire you to notice, and the only practical difference between them, is the addition of peroxide of manganese to the bath of the Bradley cell, and, although I have described them chronologically, I will first show the Jacques cell and then by simply adding peroxide of manganese to it, we will have the Bradley cell. We will then be enabled to get their comparative e. m. f. and current in the same cell. But I may say in passing that experience with these cells before you leads me to believe that the theory of their action is not by any means well understood. It is most uncertain and erratic, and seems to be more so before than after the addition of the manganese peroxide. For instance, its e. m. f. seems to depend upon its temperature. If water is present when the caustic soda is first used, a reverse current becomes manifest. When air is blown through the electrolyte the e. m. f. is increased. Sometimes only .3 of a volt is obtained; sometimes about 1½ volts. But the greatest amount of current is apparent when the carbon is immersed in the bath.

When the carbon rod is drawn up along the inside of the vessel the highest e. m. f. is obtained, and when this carbon electrode is replaced by another having none of the fused electrolyte on it, and brought in contact with the exterior of the vessel, at different points where the temperature varies, no appreciable e. m. f. is obtained. This would indicate that as we drew the carbon up out of the bath against the side of the vessel, we approach a point where the critical temperature exists and we get the highest e. m. f.

If a nickel crucible be used as suggested by Bradley some years ago, the e. m. f. is brought up to what is considered the theoretical, as you will see. This little nickel crucible contains fused caustic soda and carbon electrode, the same as in the Jacques cell. When heat is applied, you will notice that the voltage goes up to 1.16, then begins to fall and at a critical temperature above a red heat, it drops to .3 volt, a most interesting fact, and on cooling, the voltage goes up again to 1.16, and drops again when the caustic soda solidifies. You will observe that the voltage is above the theoretical. (Experiment shown.) Many other peculiar actions will be noticed if the carbon rod is replaced by an iron one. With this form of cell it is claimed that as high as 85 per cent. of the energy of the carbon consumed is converted into electrical energy. The following results of tests of the Jacques cell taken from the article referred to and from the Engineering Magazine of July, 1896, may be of interest. Electricity obtained from 1 lb. of coal (of which 0.4 lb. was consumed in the pots and 0.6 lb. was burned on the grate) equaled 1,336 watt hours, or 32 per cent. of that theoretically obtainable.

Another cell reported in the public prints to have been built and operated by Jacques, consisted of 100 iron cells 1½ inches in diameter and 12 inches deep which gave an e. m. f. of about 90 volts and 16 amperes, supplying thirty 16-candle power incandescent lamps for a little over 18 hours. In this experiment it is said that about 8 pounds of carbon were consumed in the cells. This, it was stated, gave an efficiency of over 90 per cent., which, of course, did not include the power to operate the air-pump and the coal consumed in heating the cells. But my experience with the cells before you leads me to doubt the correctness of these computations.

It has been suggested that carbon-consuming batteries would be too bulky and occupy too much space as compared with that occupied by the present central station for a given output. I find, however, that the Edison station at Duane street has a capacity of 28,000 electric horse-power. The cubical capacity of the building is in round numbers, 900,000 cubic feet. The same building crowded with Jacques cells, assuming that they would perform the work claimed for them and leaving aside the question of the difficulty of their operation, properly distributed, would have an output of 60,000 horse-power. This estimate is necessarily theoretical and based entirely upon statements made by Mr. Jacques, namely, that a furnace containing cells occupying a cubical space of 600 feet has a capacity of 40 electrical horse-power. You will thus see that this ratio is in the proportion of 28 to 60 in favor of the battery. It has been stated that the e. m. f. of the carbon-consuming cells is so low that they would be of no practical value. I think our experience with the storage battery in central stations refutes this idea; at least for potentials up to 250 volts and by means of rotary transformers the current can, if necessary, be converted into any form and pressure.

These cells, if correct in theory, can be heated without infringing on the second law of thermo-dynamics, as the law does not apply so long as the oxidization of the carbon itself does not produce heat, but electricity. For, as we have said, there is heat in the electrolytes and all matter down to an absolute zero, and the electrolyte in the practical operation of these cells, is simply heated to permit the chemical affinities acting. We are governed here, as elsewhere, by the laws of evolution, and I think that this question will be solved only through many attempts and many failures. I believe that we must look at this subject from a different point. In the first place, can we not learn a lesson from nature? We certainly have a most wonderful example of the conversion of potential energy of carbon direct into work in the animal economy, which is developed at the expense of the oxidization of the material supplied by the food, with an efficiency twice as economical as in the case of the steam engine. One-fifth of the potential energy is converted into work; four-fifths is converted into heat. But we must remember that the human body must be able to exist in the arctic regions as well as in the tropics, that the engine-room must always be kept warm, and to insure this average temperature in all parts of the earth and under all conditions, the four-fifths of what apparently is waste energy is necessary to maintain the race.

A day's work of muscular toil is laid down by the authorities at about 1,084,950 foot pounds. The normal daily expenditure in heat cannot be so readily determined; it is estimated at 6,148,000 foot pounds; that is, between one-fifth and one-sixth of the potential energy of the food is expended as mechanical labor; the remaining four-fifths or five-sixths leaves the body in the form of heat. Of course eventually the work goes into heat and is dissipated.

In the human economy the oxygen of the air is taken up by the blood in the lungs. It is carried through the arteries and attacks the tissues, giving up its oxygen and so oxidizing them, and thus producing heat; and when work is done, the equivalent of the heat disappears as work, and when the work is not done, the temperature rises, perspiration and evaporation takes place, and the temperature is kept at its normal condition, through this safety-valve. In other words, expressed electrically, there is local action as in a battery. I am aware that the question of the cause of muscular contraction is in dispute but it is generally admitted that the muscular force must be derived from chemical energy.[3]

Observe, in the first place, that nature prepares the food which it consumes to perform its functions. The food is taken into the stomach and digested. A great part of it is useless. the best part is selected and is transformed into a condition in which it can be easily oxidized at a low temperature, the blood acting as the carrier of the oxygen. Does this not give us a hint that we should follow this course likewise, and prepare the material for our carbon-consuming batteries? The oxygen of the air, we always have with us; so have we many carriers of oxygen, but an attempt so far as I know, has not yet been made along this line which I suggest, except that illuminating and other gases have been used.

A cell which I will soon show you, is one described by me in a paper read before the American Institute of Electrical Engineers in 1887. It consists of two electrodes, one of carbon, surrounded by powdered carbon, in a porous cup, and one of platinum, both being immersed in an electrolyte of sulphuric acid in a glass jar about one inch in diameter and six inches in height. Into this electrolyte when we introduce chlorate of potash we form peroxide of chlorine, which is a very unstable gas and decomposes in the presence of carbon; its oxygen attacking the carbon, oxidizes it without heat, the chlorine being set free at the platinum pole, electricity is generated with an electromotive force of 1.3 volt, varying with the amount of oxidizing agent present and with the kind of carbon used. Or, we can place these two electrodes in a vessel containing water, generating this gas outside the cell and pass it over into the cell containing the electrodes, in whch case the cell will operate the same as before; its internal resistance being regulated by the amount of sulphuric acid we may wish to add to the water.

You will notice that when the electrodes are immersed in the sulphuric acid, that only a slight e. m. f. is indicated, due to the combination; on the addition of chlorate of potash, the e. m. f. is about 1.3 volts per cell and the current about .4 of an ampere. To show you that the action is strong and the oxidization of carbon rapid, I will connect the cell with this little electric bell, which will give you an idea of its strength. (Experiment shown.)

We have been taught to believe that the e. m. f., due to the oxidation of carbon, is about 1.05 volts. This value has been arrived at by assuming Andrews' determination, that the oxidization of one pound of carbon to CO_2 equals 14,544 B. T. U.; or that one gramme equals 24,944 foot pounds. This determination was only approximate, and further, it was a determination made at a very high temperature. Now you have seen that the oxidation of carbon in this cell without heat has produced 1.3 volts, and would produce even more if we chose to concentrate the peroxide of chlorine present, which is rather a dangerous operation, as the gas is an explosive one under some conditions. So it would apparently appear that there are more foot pounds of energy in a pound of carbon than shown by Andrews, unless the additional energy in this instance comes from the peroxide of chlorine.

It might be thought that the high e. m. f. obtained in this cell is due to the action of the nascent chlorine on the platinum, but careful measurements have determined the contrary.

We have here, therefore, a cell in which carbon is oxidized without the application of heat and at normal temperatures; a cell in which oxygen in unstable composition is readily given up to the carbon and the product of the oxidization is carbonic acid gas, as proved by analysis. I think we have, therefore, the right to assume that a large percentage of the potential energy of the carbon is converted into electrical energy. The point I wish to make in this connection is: We have in this cell, conditions which are analogous to those taking place in the human system, at least to the extent that carbon is and can be oxidized at the normal temperatures under which we live, and its potential energy converted into electricity.

We have in the blood of the human economy a carrier of oxygen, called haemoglobin; it absorbs its oxygen through the lungs, each gramme taking up 1.34 c. cm. of oxygen; this oxygen is in such unstable condition that it can be extracted from the blood by means of a vacuum and by means of most reducing agents; yet it has the power to oxidize carbon and hydrocarbons as the body provides them, without external heat.

We have in this test-tube, water containing haemoglobin in solution. You will see that by transmitted light, it is of the color of arterial blood, as it is fully oxidized, and when a reducing agent is added to it, and the air excluded, you will see that it becomes the color of veinous blood, and when the air is again admitted, it takes up the oxygen and becomes arterial in color. This game can be played, of give and take and oxidizing and de-oxidizing as many times as we like. Even carbon reduces it and gives an e. m. f. (Experiment shown.)

What I want to express to you is this: In this battery which I have just shown you, carbon is completely oxidized at normal temperature by oxygen which is held in loose combination. So it is done in the human body, and we know that to be a very efficient machine. Therefore I see no reason to think that it is necessary for us to use high temperatures. Keep without the second law of thermo-dynamics; search for a suitable carrier of oxygen or some cheap source of oxygen supply and hydrogen or carbon; or a carbon compound easily oxidized.

Does it not seem logical that by following along this line and by preparing the material to be consumed, as nature does in the human body, we may yet be able to reach the desired end with economy? Is it not probable, judging from human experience, that within the wide range of materials, some cheap means can be found? I believe it is. Like all good things in nature, it will come through many trials and failures. The struggle for existence will perfect it, but there is no known law which indicates that we are dealing with the impossible.

SOME RECENT DEVELOPMENTS IN COPPER MANUFACTURE.

BY HAROLD P. BROWN.

In these days of keen business competition, makers of electrical apparatus and machinery are quick to seize upon each advance in the arts which will reduce the cost of material or increase the daily output of their shops. And the alert engineers in our large electric power houses are always ready to adopt improvements which will effect a saving of power. Both of these classes will, therefore, be glad to learn of a discovery in metal handling which will reduce cost and save time and power.

It has been considered impossible to obtain solid castings of copper without mixing with it some other material. And it is well known that even one-half of one per cent. of alloy is enough to reduce the electrical conductivity of the casting to one quarter that of pure copper. Many processes of mixing or tempering this metal have been invented but their product has not up to this time been able to show the physical properties of rolled or drop-forged copper.

Some months ago in a new type of rail bond I used strips of rolled copper with cast copper terminals. These castings were made for me by a firm which claimed extraordinary things for their product. I therefore, expected very little from the metal, and in making tests was greatly surprised to find that a piece of this metal with but ⅝ of a square inch section, could transmit 1,500 amperes for twenty minutes without excessive heating. A calculation based on this performance indicated a conductivity of at least 90 per cent. that of the best rolled copper.

As I had never before found cast copper with more than 40 per cent. conductivity, I decided to make a thorough and complete series of tests so as to ascertain the facts concerning this metal, which is called MB copper. A chemical test suggested by Mr. Edison showed that these castings had less impurity than was contained in some sheet or rolled metal sold as pure electric copper.

To exactly determine the relative conductivity, I ordered a pattern made from which I obtained castings of the best commercial copper and of the MB metal. These castings were carefully finished so as to present for testing a cylinder 25 inches long and 0.8 inch in diameter; a terminal was left at each end, about 2¼ in. by 2¼ in. by 1 in. As a basis for comparison I had an exactly similar bar turned up from the best rolled Lake Superior copper. The completed bars were magnificent pieces of metal, without an apparent flaw. The difference in shrinkage of the two castings and a slight variation in the size of the terminals made it impossible to exactly obtain the comparative weight. The terminals of the rolled bar measured 2 in. by 2 7-16 in. by 1 in. and its weight was 7 lbs. 6 oz.

The commercial cast bar was a popular process, "Tempered" copper with terminals 2 1-16 in. by 2⅛ by 1 in.; its weight was 6 lbs. 9 oz. The MB bar's terminals measured 2 in. by 2 3-16 in. by 1 in., and its weight was 7 lbs. 1 oz. Each of the cast bars gave a clear musical tone when suspended and struck; the MB bar, though the heavier, gave the higher tone. Of course the rolled bar was without resonance. The commercial cast bar had accidentally been turned 0.002 of an inch too small, but the other two measured exactly 0.8 of an inch, thus having a section of practically one-half a square inch.

---

[3] Proceedings Royal Society, March 12, 1895.

I decided to test the electrical drop in two feet of each bar and its temperature at from 100 to 1,500 amperes, the latter being three times the proper current for that section of copper. In order to prevent any rise of temperature from the contacts at terminals, each terminal was amalgamated by the Edison process and coated with the Edison flexible solder; there was, therefore, no appreciable drop at these contacts. In amalgamating the commercial copper bar by the Edison process, fumes were given off with an odor of zinc, and a black precipitate was formed. This was washed off and the process repeated several times until the surfaces remained bright. Both of the other bars yielded instantly to the process without fumes or precipitate.

Mr. Edison states that this is a keen test of the purity of copper and so it proved, for the analyses subsequently made for me by Ledoux & Co. showed the commercial casting to have 99.15 per cent. of copper; the rolled bar 99.83 per cent. and the MB 99.85 per cent. In spite of the different characteristics of these bars, the variation in composition is less than seven-tenths of one per cent.

From tests of similar samples, the tensile strength of the commercial cast copper was 19,000 lbs. to the square inch, while the MB was 30,000 lbs., which is practically the same as rolled copper. The cables used for connections were 500,000 cm. with triple braided insulation. When heavy currents were used the bare ends of the cables near the bar connections were cooled with wet waste. The observed temperature of the bars was, therefore, not due to any outside cause. The instruments used were all made by Weston and comprised a shunt ammeter reading up to 1,500 amperes; a millivoltmeter reading 0.0002 per degree up to 0.01 volt; another reading 0.002 per degree up to 0.1 volt and a third reading 0.01 per degree up to 1.5 volts. In each case the same voltmeter terminals were used; these were clamped upon amalgamated spots on the bars just 24 inches apart. A special dynamo driven by Edison motors was used; its field was excited from the Edison mains; by using a rheostat and a bank of lamps, the amount of current generated could be accurately adjusted.

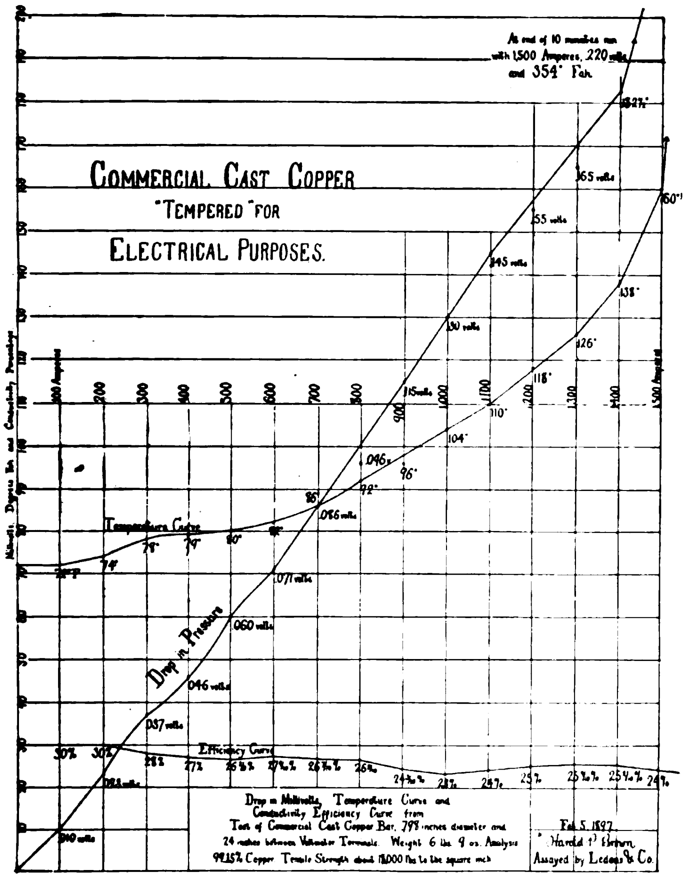

FIG. 1.

The first readings were taken at 100 amperes after about one minute's run; the current was then increased 100 amperes and a second reading taken, and so on until 1,500 amperes was reached. This amount of current was continued for ten minutes and increase of the temperature and drop noted. The bars were then disconnected and laid upon a wooden floor and their rates of cooling noted. Since the copper resistance tables are either calculated for a constant temperature or were compiled years ago from data based on impure copper, I decided to use as a base of comparison, the drop of the rolled copper bar at each 100 amperes. Since the performance of the MB copper came so close to this standard, I repeated the tests on each and found the readings accurately recorded.

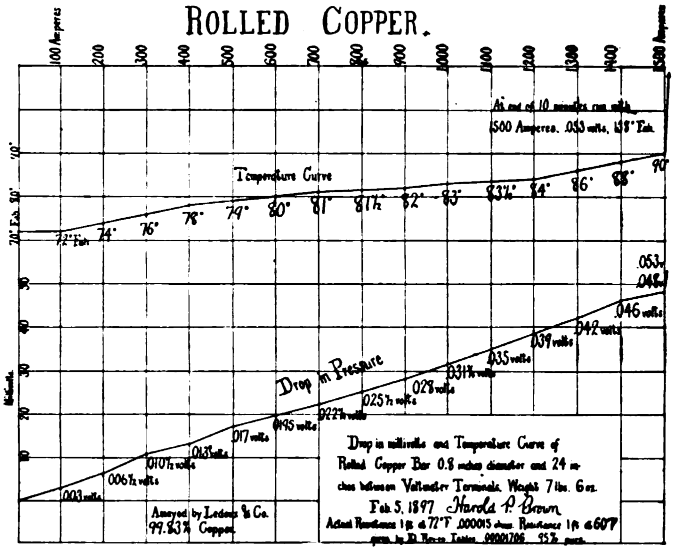

FIG. 2.

The accompanying curves will show the behavior of the three metals under exactly the same set of conditions. The commercial cast copper, Fig. 1, averaged less than 28% conductivity, and before the end of the run scorched the wood on which it rested and the cotton covering of the thermometer bulb, as it reached 354 degs. Fahr. and 0.22 of a volt drop. Before the test the color of this piece was fine and closely resembled that of the other bars; after the test the bar was a mass of red and silver colored spots and had lost nearly all its resonance. At the end of the run it had expanded from increase of temperature ⅛ of an inch in 24 inches and 0.002 of an inch in diameter.

Allowance should be made for its difference in size. It required two hours and twenty minutes to cool to the temperature of the room. The rolled copper showed a conductivity far greater than called for by the tables ordinarily used. Its actual resistance per foot at 72 deg. Fahr. was 0.000015 ohm. In the table published by the London Electrical Review, the resistance of a piece of copper, 95 per cent. pure, one foot long with a section of one-half a square inch, is said to be 0.00001706 at 60 deg. Fahr. Without reducing to the same temperature, the latter resistance is 13 7-10 per cent. greater than the resistance observed.

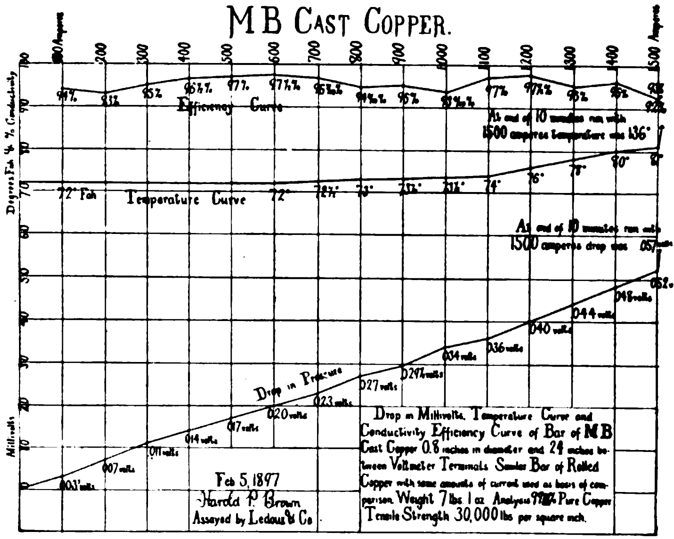

FIG. 3.

The tables based on the Matthiessen standard of conductivity also show greater resistance; it is therefore wise to use an actual measurement of modern rolled copper as a standard of resistance for cast copper.

The rolled copper bar at the end of the ten minutes run with 1,500 amperes, reached 138 deg. Fahr. and 0.053 volt. It had then increased one-eighth of an inch in 24 inches as did the other, but the diameter increased 0.0005 instead of 0.002 of an inch. It required one hour and twenty-three minutes to cool. See Fig. 2.

The performance of the MB copper was a surprise and remains a puzzle. In the test it kept 8 to 10 degrees cooler than the rolled bar up to a load of 1,400 amperes. At the end of the ten minutes run with 1,500 amperes it reached 136 deg. Fahr and 0.056 volt. Its increase of size was the same as that of the rolled bar. It required one hour and thirty-nine minutes to cool. See Fig. 3.

The varying temperature of the two bars evidently accounts for the up and down movement of the efficiency curve, between 94 per cent. and 97½ per cent. If in the tests the temperature of the bars should be kept at 72 degrees by allowing time for cooling after each reading, it is my opinion that this curve would be practically a straight line at 95 or 96%.

I need not say that this conductivity is marvelous and opens an entirely new field for dynamo and motor construction and for switch board work, where a large saving can be effected by using it in place of rolled or drop-forged copper, both of which will warp or twist when heated, while the finished cast metal retains its shape. I know of large multipolar dynamos upon which castings of low conductivity have been used for field coil connectors, etc.; on account of the unsuspectedly high resistance of these contacts, the calculations concerning compounding have been upset and the dynamos have been failures. Another surprising quality of these MB castings lies in their elasticity. I have fastened in a vice one end of a casting 1 inch wide and ⅜ of an inch thick; the other end, 12 inches distant from the point of support, was bent one inch out of its position but sprung back when released. I have driven through a ⅞ inch hole in a hardened steel plate, a plug of MB metal 57-64 of an inch in diameter. This required as many hammer blows on the fifth trial as it did the first.

In another experiment I drove into an opening 1 9-16 inches wide between heavy steel rails, a plug of MB copper cut in two pieces lengthwise, the sum of whose widths was 1 19-32 inches, thus compressing the metal 1-32 of an inch. A current of 1,500 amperes was then passed through the junction whose section was ⅜ of a square inch, and a drop of 0.018 volt was indicated from rail to rail through the two copper pieces in series. The rails were then separated 1-32 of an inch more, but the drop remained the same, showing that the copper had resumed its previous width. An analysis of another sample of this MB copper gave the following results:

Copper	99.870	per cent.	Bismuth,	None,
Silver	.034	"	Lead,	None,
Iron	.011	"	Cobalt,	Trace,
Arsenic	.002	"	Sulphur,	None,
Zinc	.013	"	Oxygen,	(by difference)
Tin	None.			.068. 0/0.

This analysis is verified by others made by such experts as Ledoux & Co., Booth, Garrett & Blair, Prof. Frank X. Moerk, and others, and shows exactly the same results as the best Lake Superior copper. It is evident that no alloy has been used. And yet the process has increased the electrical conductivity and the tensile strength; has given a certain amount of elasticity and decided resonance; has increased the density and changed the structure of the metal.

On presenting this matter to Mr. Edison he accounted for the evident change in the structure of the metal by the theory that the shape of the crystals has been altered so that their lines are parallel, and that the molecules are thus brought closer together and into more intimate contact with each other.

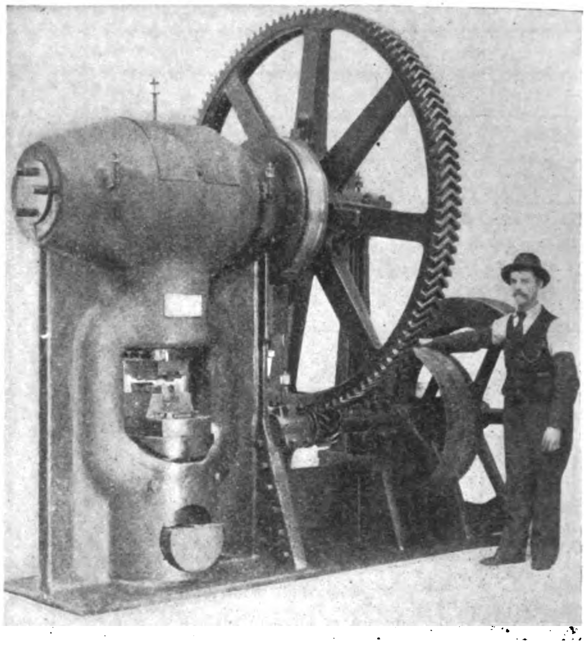
The fact that MB copper can also be rolled or forged adds new interest to its development. As its tensile strength exceeds that of ordinary copper wire, it is certainly worth while to make wire from it in order to determine its strength and conductivity. If it is possible by this process to make as large an increase in the conductivity of wire as it has made in conductivity of cast copper, it will revolutionize dynamo and motor building, and every electric light and railway company will save money by using it to replace its present line wire. And if the tensile strength of the wire is increased by the process, poles can be set further apart and the wire will be less likely to decrease its diameter during winter. This metal is well worth the attention of all electrical engineers who appreciate the value of high conductivity.

It is understood that Mr. Edison is interested in the development of the process and that the MB copper will be manufactured under his supervision at the celebrated Menlo Park **Works.**

MECHANICAL

OTTUMWA IRON WORKS' NEW PRESS.

THE press we illustrate is something new in this line and is designed for use where extra heavy pressure is required. It weighs 24,000 pounds, has a steel shaft 11½ inches in diameter. Its frame is made of one casting, in which the shaft is supported by a bearing at each end. This double bearing for the shaft greatly increases the crushing power of the press. The adjustment is by a wedge which is moved back and forth under the anvil, or die support, by means of a screw. This allows the die to be raised or lowered while the press is in operation, and secures a very fine and accurately determined amount of adjustment. Its strength is largely increased and rendered noiseless by the use of a spiral gear and pinion. The gear wheel is 82 inches in diameter, working in a pinion of 7¼ inches.



PRESS MADE BY OTTUMWA IRON WORKS.

The press has been developed in the shops of the Ottumwa Iron works, for the purpose of doing a class of work that they were unable to get a tool of the kind to do. It is especially valuable in doing such work as cold forging steel articles, or shaping forks or spoons, or bringing steel pieces to a uniform thickness. Tool steel blocks, 1 inch square by 1½ inch, and varying in thickness 1-16 inch, by being pressed through this press once, will be brought to a uniform thickness to within less than 1-1,000 inch. This is a great deal cheaper than milling them, and quite as accurate. The press is built by the Ottumwa Iron Works, Ottumwa, Pa.

SIDE CRANK MEDIUM SPEED ENGINE OF THE BALL ENGINE CO., ERIE, PA.

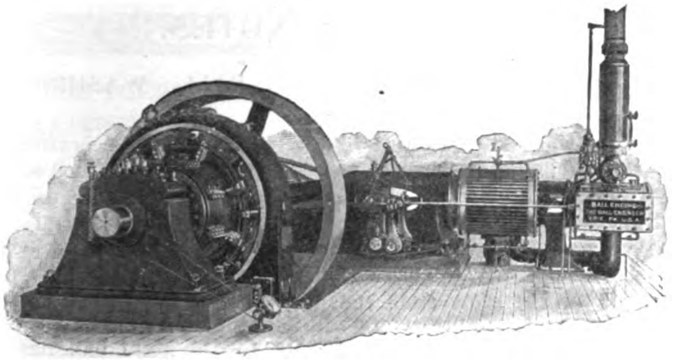
THE accompanying engraving represents the new side crank medium speed engine just brought out by the Ball Engine Company, of Erie, Pa., and designed particularly for railroad work. Keeping in view the extremely severe condition of electric railway service, all the parts of this engine are unusually liberal, and every possible refinement in adjustment and manipulation has been incorporated.

The bed is symmetrical and contemplates provision for every strain that may be put upon the engine in service, and is an exceptionally excellent example of mechanical designing and rigidity. Towards the upper end the bed becomes a round circular column, having on two sides of the finished surface the crosshead guide surfaces, which are bored coincident with the boring and facing for the reception of the cylinders. The two sides are pierced with elliptical openings, making easy access to the crosshead or upper end of connecting rod.

The crosshead is of the double-plate pocket type, used by many makers of Corliss engines, and is provided with taper shoes to compensate for any wear that may occur against the guides, the shoes being of cast iron and running surfaces spotted with genuine babbit metal, the area of which is very liberal.

The introduction of the shaft into the engine is accomplished by arranging the shaft boxes in a large jaw cutting into the bed deep enough to bring the center of the shaft in a plane with the center line of engine, finished spots being provided to meet corresponding finished surfaces upon the cast iron boxes. The shaft boxes are adjustable by means of screws.

The crank shaft is one solid piece of 40-carbon open-hearth forged steel from end to end, and ground to a perfectly round, smooth running surface. Surrounding the crank throw is a disc carrying sufficient amount of counter-weight to give a running balance to the crank and to the reciprocating parts, so there is no vibration to be communicated to the frame and other working parts of the engine. The connecting rod is of forged steel, hammered down from a solid bloom, with both ends cut out to receive the crank and crosshead boxes. The adjustments can be made by hand with a great degree of accuracy.



THE NEW TYPE OF ERIE BALL ENGINE.

The high pressure valve is of the double-face telescopic type, receiving the boiler pressure on the inside, there being a sufficient amount of unbalanced area on the faces so that the force of the steam on the inside forces the two faces apart, causing each to rub against the seat with a sufficient force to keep the surfaces polished and steam tight through the entire life of the engine. The low pressure valve is of the common letter D type, with improved construction and proportion; is provided with a round relief area upon its back, operating against the chest cover, thus having a large, well-proportioned valve that runs with the greatest ease, yet follows up its wear without attention from the outside.

The outboard bearing has the same form of boxes and adjustments as the main bearing, and as a very liberal amount of metal is employed, makes a strong and substantial support to the outer end of the shaft. The material used in the piston rods, valve stems, rocker shafts, and crank pins is the best crucible steel, which, on account of its hardness and strength, gives the greatest possible amount of wear.

The governor, which in the engine shown is in the fly wheel, is quiet in operation, quick in action, perfect in regulation, and is especially adapted to the sudden shocks of railway service.

LITERATURE

COIL AND CURRENT. By Henry Frith and W. S. Rawson. London and New York: Ward, Lock & Tyler. Cloth. 294 pages. Freely illustrated. Price $1.25.

This is an excellent work, of the popular class, and gives an admirable idea of all the great triumphs and advances in electricity made since the beginning of the art and more particularly during the present century. It gives first a brief review of the history of electricity, and then takes up in succession the telegraph, the electric light, the electric motor, and the electric railway, space being also given liberally to the telephone, welding, plating, deposition and the miscellaneous uses of electricity. Each part is carefully yet lightly handled, and the technical information is interspersed with a multitude of stories, old and new. The book is thoroughly abreast of the latest work, and while it necessarily contains some historical cuts of familiar aspect, it is brightened up by a large number of new and graphic illustrations. In some sections the variety of new illustrative material is quite pleasing. The book is well printed and appears in a stout, decorative binding.

LETTERS TO THE EDITOR

MR. WINCHESTER ON MUNICIPAL PLANTS.

I DESIRE to express my sincere thanks to you for the high though undeserved compliments paid me in your editorial comment upon the subject of municipal ownership of electric lighting plants in your issue of February 17.

It would have been more pleasing to me, however, to have noted an intention in your editorial and selected articles to treat the subject with impartiality which was apparently lacking, as evidenced by the spirit of your comments upon my report and the array of articles descriptive only of unfavorable extremes and exceptional conditions without throwing any light upon existing successful municipal plants which it would seem should have been included to faithfully carry out an intention to be impartial. The fact that there are no successful municipal plants in existence cannot be offered as a reason why they were omitted, as your fund of data upon the subject must demonstrate. You know and so do I, as well as any one else who has investigated these plants, that there are many such in highly successful operation to-day.

You implied that my report presented a poor case as an argument in favor of municipal ownership. Perhaps you are right; I never was good at an argument, but have always had the greatest respect for facts. The list of plants contained in my report was made up of the good and the bad without partiality and a careful study of it does not bear out your statement, but clearly shows a majority of plants which cannot be distorted so as to represent anything but successful institutions as tax reducers. My report was the result of many months of investigation and hard study with this one end in view, to get at the actual facts.

The time given by you to analyze the report probably consumed a matter of a few hours, considering the many other matters which demand your attention. Had you taken more time I doubt not in your desire to be fair, that your criticisms would have been more substantial.

As to being a champion of municipal ownership of electric light plants, I can hardly accept such a high sounding title in the sense it was bestowed, and must modify it by saying that I only champion that side of the question in instances where municipal plants can be a benefit to the people who want them.

I regret that you represented me as being so narrow as to believe that men of one section are more honest than those of another, to which reasoning you implied that I attributed the success of our South Norwalk municipal plant. I said nothing which could be so construed. As a matter of fact our citizens are largely composed of New York City business men, including myself. Nor did I say or imply that I was not in favor of municipal plants for large cities, but I do adhere to the belief that any city, large or small, already possessed of well managed private electric light plants which are conducted on broad principles, fair and satisfactory to the people, supplying excellent service at low rates, of such character as are found in New York City and most of the other large cities, are not in need of municipal plants.

The municipal plant has a broad field of its own to fill without conflicting with the vested rights (so called) of private corporations that recognize their worth. Vested rights in public matters are the property of the people who it should be understood can give or recall them at will, and are never the unconditional property of individuals.

The field of the municipal plant is to afford relief to places which are burdened with cheap plants owned by speculative private corporations which in return for valuable franchises often given them gratuitously by municipalities in good faith, supply miserable service at maximum rates, making the public pay not only the cost of the production and a fair profit, but also for the losses due to poor construction, uneconomical machinery and bad management.

The success of the South Norwalk municipal plant should in justice be credited to my two brother commissioners, Mr. Joseph A. Volk, a keen, practical business man of experience, and Col. Leslie Smith, an honorably retired officer of the United States Army, a man of method and discipline. Both men are the embodiment of honesty, and the citizens by whom they have been repeatedly elected and re-elected to public positions of trust and importance, have the most implicit faith in them. Their interest in the success of the plant placed in their charge could not be exceeded if it was their own personal property and it is my pleasant privilege to be their associate.

All must bend to the power of the public, which is deliberate and slow, but sure in action; and the unwise electric light corporations that have misused public confidence can but trace the blame to themselves for the advent of the municipal plant, to-day nearly 400 strong in this country, and in a state of incubation in about 300 more cities and towns.

Let me ask how in justice can such figures as you publish from the Utica report be accepted as reliable? Do they not show how readily anything derogatory to the municipal plants is swallowed even by a journal as broad and intelligent as The Electrical Engineer? The data in that report is most incomplete. Nothing is said as to the number of lamps furnished by the plants quoted, and the candle power per lamp, price of coal, whether or not the plants are exclusively engaged in arc lighting, or, in fact, any information which would account for the extreme variations in cost per lamp hour, or candle power ratings for one cent as given—just figure some of those rates backward and note the unheard of phenomenal yearly results. The size of the plant and its various physical conditions, make all the difference in the world. A large number of lights cost less to produce pro rata than do a small number, as we all know; therefore without fuller explanation the Utica report cannot be justly considered as a criterion of true facts. Had that same report been made in favor of the municipal side, how quickly the minor failings that I have been able to note casually would have been jumped on and perhaps many others which my comprehension has been too dull to grasp.

I can speak personally in stating that the figures relating to the South Norwalk municipal plant as given in the Utica report are wrong and show evidence of careless, mistaken, or intended distortion so as to make the municipal side appear to a disadvantage. As a matter of fact, the correct South Norwalk figures including interest, depreciation and all operating, expenses, are, cost per lamp per hour, .0265 cents, candle power per hour for one cent 453, instead of .0571 cents per hour in the former case and 280 candle power per one cent per hour in the latter, as the Utica report states. Who made the report anyhow?

I for one would be pleased to see this question treated without partiality for once. All that is asked is justice. If the municipal plant is wrong let its opponents prove their statements by facts that will stand investigation, and not by assertions, assumptions, extremes and distortions. While this sort of ammunition is being used, the popular municipal "fad" is capturing city after city. If it is wrong, it must be crushed by just condemnation, but if it is right, no power can impede its advancement.

Again thanking you for the high esteem in which you hold me, which is most bountifully reciprocated, I am ever yours for progress,

ALBERT E. WINCHESTER,
Electric Light Commissioner.

South Norwalk, Conn., February 20, 1897.

PROF. THOMSON AND THE ENCLOSED ARC LAMP.

As the enclosed arc has taken a clearly defined position in the art of electric lighting of to-day, it is interesting to note the appreciation by scientists in the early days of commercial arc lighting of what we know to-day to be its essentials. The articles which have appeared in The Electrical Engineer by Prof. Marks are interesting as showing the development of this improvement, and from these articles it is quite evident that the utility of the enclosed arc depends solely upon the capacity of the apparatus to slowly replace the effects produced by air, the change being gradual and capable only of maintaining life and clearness to the enclosed atmosphere in which the arc is maintained, without the rapid consumption which is the result of unlimited quantities of air being supplied to the electrodes.

This then is the secret of success of the enclosed arc, and while these features have been, by the articles referred to, accredited to recent date, they were as a matter of fact fully known, illustrated, and described by Prof. Elihu Thomson in 1879, and also known to others at that time to be his invention. Among the evidence of this was a most complete specification for an application for letters patent prepared in February, 1879, in the handwriting of Prof. Edwin J. Houston, and signed by both Profs. Thomson and Houston, which became evidence in an interference proceeding between Prof. Thomson and myself upon the question of priority of invention of another matter. In this writing is described the advantage of excluding almost all fresh air from the enclosing globe to reduce the consumption of the electrodes and increase the longevity of the arc from a pair of carbons. Furthermore, means are shown and described to insure the very slow and gradual supply of air and escape of products of combustion so necessary to avoid blackening and bursting of the globe. In addition to this, the lamps are shown as arranged for constant potential circuits.

While all this may be deemed as too ancient to be considered more than as historical, nevertheless, it shows how possible it is for an inventor of the character of skill possessed by Prof. Thomson to foresee the necessities likely to arise in the future. This evidence, it seems to me, shows Prof. Thomson to be the first to devise and suggest the essentials for successful working of the enclosed arc.

R. M. HUNTER.

Philadelphia, Pa.

NEWS AND NOTES.

ELECTRICITY AT THE INAUGURAL BALL, WASHINGTON.

Having abandoned the elaborate plan of street decorating by illuminated arches, the committees in charge turned all their energies practically to the beautifying of the inaugural ball room. The streets and squares will nevertheless be equal to the occasion, Pennsylvania avenue, with its score of reviewing stands, several having the length of a whole block, will receive the glow from the firework display, and many beams from electric projectors will lend their peculiar charm. The Pension Building, the chosen place for the great ball, has been equipped with three covered approaches 15 feet in width, each having a covered carriage siding 75 feet long. On entering the main hall one can scarcely believe it to be the same building, the covering and decorative effects have been so thoroughly carried out. The colors are universally white and yellow in draperies, making the ball room an easy one to light up. The lighting is effected from almost every side. The main floor is bordered by 150 two-column in two tiers, the capital of each column mounting a cluster of sixteen 8 candle-power lamps, arranged in sunbursts and wired in multiple directly to 110 volt mains on the three-wire system. The use of nails or screws was prohibited, and all the clusters were attached to the columns by wooden strips and iron bands. These 2,232 lamps are fed from six temporary cables, three making the rounds of the hall on the main floor and three on the ceiling of the first gallery, tappings being made at each column. The electrical contractor fortunately had the use of a steel rail running around all four sides of the building on both gallery and main floor, which is used as a trolley conveyance for moving heavy articles, this rail furnishing all the support that could be wished for, as the cables are conveniently suspended by wooden blocks and insulators. Above the double tier of incandescent clusters a "necklace" of arc lights is strung around the building wired in series. Series arc lamps also furnish light temporarily located on the numerous stairways which lead from the main floor to the two promenade galleries from which a grand view of the hall can be had. Above the arcs and in the center of the hall three wooden-ribbed domes are suspended, each thirty-five feet in diameter, lined with white and yellow cheese cloth, and having a fall of white cheese cloth in all directions skillfully caught back, concealing the tremendous iron girder roof. Each dome is outlined by 115 lights. The domes are suspended from the roof by four ropes each, the ends of the ropes branching out to three ends, thus giving the frail ribbed dome twelve points of support around the base. Twenty-five hundred 6 candle-power lamps are wired through the palms and floral decorations, and 500 in addition go to outline an American flag over the entrance, and an eagle and shield with the names of McKinley and Hobart, over the band stand, which is situated midway in the hall. A golden gate forms a striking decoration at the farther end of the hall, both band stand and arch having clusters of incandescent lamps; the effect is very brilliant. A decorated fountain makes a center piece for the main floor. The cost of the electric work, including the supply of current, also gas turned down low, is $4,670. The electric work was carried out by John R. Galloway, contractor, of Washington, D. C. An illuminated canvas on the roof displays the number of the carriage called, in figures several feet in height. Among the non-electrical things of interest is the temporary kitchen adjoining the building, which is seventy-five feet in length, and equipped with every convenience of modern design. N. M. H.

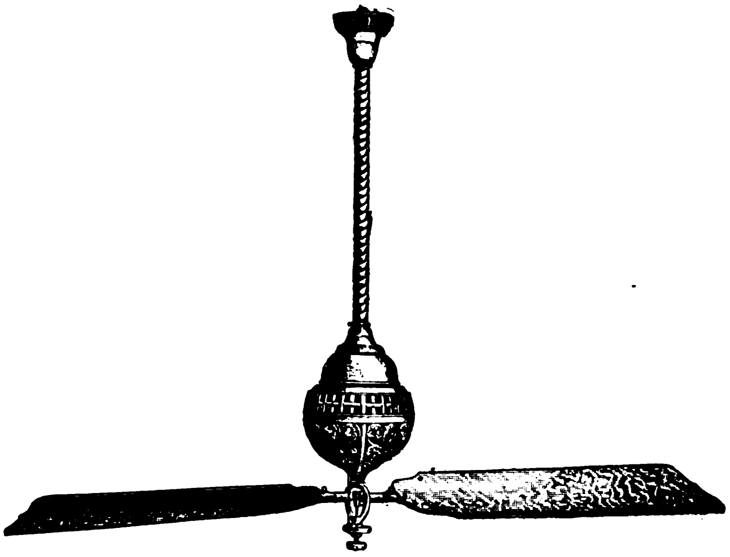
THE COX LABORATORY, at St. Albans, England, has, we regret to learn by cable, been destroyed by fire. The details of the event are not given, but it is hoped that no delay will be caused in the manufacture and delivery of the Cox thermo-generators, for which a large demand has already sprung up.

CASSIER'S MAGAZINE for March prints in handsome form the complete revised text of Mr. Tesla's poetic speech on Electricity, delivered at the Buffalo banquet last January. It is accompanied by some admirable pictures of the work at Niagara.

POWER TRANSMISSION

THE TUERK ALTERNATE CURRENT CEILING FAN.

WITH the approaching summer season we may look for the ever increasing demand for that now indispensable adjunct to comfort, the electric fan. Where the spaces to be ventilated are large the ceiling fan has been found exceedingly useful, and among those who have devoted their attention to this particular class of work are the Hunter Fan and Motor Company, of Fulton, N. Y., who are now bringing out their 1897 type of Tuerk alternating ceiling fan, which enjoyed such well-merited popularity during the last summer season. The new fan is shown in Fig. 1. The 1897 model's new features consist first of a switching device which greatly facilitates the control of the fan; to this has been added an enlarged oil chamber, so that one filling is quite sufficient to carry the motor through a whole season or longer, if desired; and besides this, a number of improvements have been introduced in the construction of the outfit which will be appreciated by users.



THE TUERK ALTERNATING CURRENT CEILING FAN.

Our engraving, Fig. 2, shows the highly ingenious mechanical arrangement for reducing the speed and transmitting the power from the motor to the fan blades. As will be seen, the new switch is operated in connection with the blade adjuster, the upper wheel operating the switch, while the lower wheel adjusts the blades, which may be done while the fan is in motion.

It will be noted that the transmitting gear consists of a shaft with a beveled transmitter wheel. The case inclosing the motor carries the fan and intermediate bevel wheels faced with leather. These wheels engage interiorly with the pulley and exteriorly with the inner face of the case; with this arrangement, the case rotates around the motor, but at a much lower speed. The transmitting wheels are mounted in swinging frames hinged to the stationary support which carries the motor case, and the weight of the fans and outer case is utilized to produce and maintain the frictional contact of the wheels that support the case and fans. Thus the friction is always the same, and any wear on either pulley wheels or case is automatically taken up, and the fan speed is thus always at a fixed ratio to that of the motor.

It will readily be seen that by this construction the friction on all the journals is reduced to a minimum, there being no cramping strain, all shafts being perfectly balanced and stepped with a single hardened steel ball, supported by a hardened steel screw. Means are provided for circulating the oil, and all shafts are set vertically so that the oil cannot run to waste. Means are also provided for carrying the motor case in a vertical position in the outer revolving case, by providing the case with a tubular stem, in which the armature shaft is journaled and the outer case is provided with a tubular shank, which revolves along the stem, while the armature shaft revolves within it. The letters B, C, D, D, Fig. 2, show the oil reservoir.

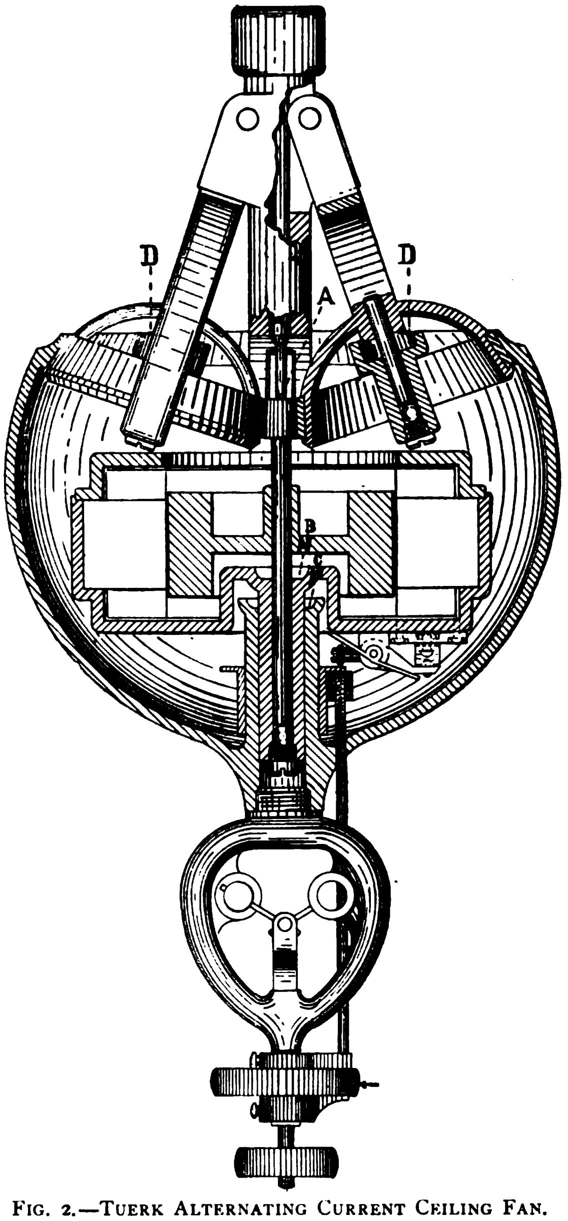


FIG. 2.—TUERK ALTERNATING CURRENT CEILING FAN.

The new Tuerk ceiling fans operate on any of the standard alternating systems and at different voltages ranging from 50 to 120 volts. The actual energy consumed by these motors is from 120 to 140 watts depending wholly upon the angle of the blades, which are adjustable and can be set at any angle desired. The fans are finished in Bower-Barff, bronze, ivory and gold, full nickel and polished cast brass.

The selling agency for the Hunter Fan and Motor Company for the entire East will be under the management of E. B. Latham & Co., 136 Liberty street, New York.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED FEBRUARY 23, 1897.

Alarms and Signals:—

ANNUNCIATOR. A. R. Miranda, Boston, Mass., 577,532. Filed Nov. 17, 1896.

Intended for use in barbers' establishments, to announce automatically the abandonment of a chair by a customer.

ELECTRIC SIGNAL FOR HIGHWAY CROSSINGS. W. W. Alexander and M. C. Gillham, Kansas City, Mo., 577,635. Filed March 23, 1896.

System for single track railways whereby a train approaching a crossing from either direction causes an alarm to sound and to cease directly it has passed the crossing.

Batteries, Secondary:—

SECONDARY BATTERY. H. G. Morris, Philadelphia, Pa., 577,771. Filed Sept. 5, 1895.

A cell having supports therein below the liquid level, a battery plate consisting of sections connected together by necks, the upper section being in the form of a beam from which the other sections are suspended, the beam section being part of the active plate within the liquid and resting upon the supports within the cell.

Connectors, Conduits and Insulators:—

ELECTRICAL INSULATOR. T. W. Young, Washington, D. C., 577,704. Filed Sept. 23, 1895.

A conductor of electricity in combination with an electric heater arranged in proximity to a support of the conductor and a hood for shedding water away from the electric heater.

Distribution:—

ELECTRIC TRANSFORMER. L. Gutmann, Peoria, Ill., 577,480. Filed April 25, 1896.

An element plate for electric transformers, consisting of the combination of two punchings, each having two limbs at an angle to one another, and a recess in one or both of them, and a third punching adapted to be retained in two oppositely located recesses of the two punchings named first.

ELECTRIC TRANSFORMER. L. Gutmann, Peoria, Ill., 577,742. Filed April 25, 1896.

An electric transformer element combining two U-shaped pieces of magnetic material, whose butting joints form the letter Z.

DEVICE FOR CONTROLLING LIGHT EFFECTS. H. V. Arnold, New York, 577,816. Filed Feb. 24, 1896.

Means for controlling the different colored media used in so-called "light-effects."

Dynamos and Motors:—

ALTERNATING CURRENT MOTOR. L. Gutmann, Pittsburg, Pa., 577,427. Filed Feb. 4, 1891.

Consists of a field magnet, an armature whose windings are subdivided into coils, contact terminals for the subdivided windings and a brush adapted to rest permanently on one armature-terminal and temporarily on the others.

Electro-Metallurgy:—

ELECTRIC FURNACE. F. J. Patten, New York, 577,493. Filed Aug. 1, 1896.

A central carbon core constitutes one electrode of the furnace, having numerous pencils of carbon radiating from it through the mixture to be fused, the outer extremities being connected to independent leads whereby they can be given current simultaneously or separately at will.

PROCESS OF AND APPARATUS FOR TREATING ARSENIC ORES. G. M. Westman, New York, 577,802. Filed July 8, 1895.

Consists in melting the ore by means of an electric current, one of the electrodes in the circuit being a stratum of lead, beneath the ore, with which the precious metals unite while molten, and, second, condensing the arsenical vapors given off from the ore while melted, simultaneously with the precipitation and union of the precious metals with the lead.

Lamps and Appurtenances:—

FILAMENT FOR ELECTRIC LAMPS. J. H. Douglas-Willan and F. E. W. Bowen, London, England, 577,499. Filed Aug. 3, 1896.

A process of treating filaments consisting in rendering them incandescent in the presence of a compound containing boron, carbon and oxygen.

ELECTRIC ARC LAMP. G. M. Lane, Asbury Park, N. J., 577,760. Filed Jan. 4, 1896.

Cut-out for arc lamps.

Measurement:

VOLTMETER. P. Brandt, Berlin, Germany, 577,678. Filed Aug. 6, 1896.

A core for solenoids, comprising a soft iron sleeve, and a bundle or cluster of wires contained therein.

Miscellaneous:—

PROCESS OF MANUFACTURING OZONE AND BY-PRODUCTS. G. J. Andersson and J. C. Dittrich, Brooklyn, N. Y., 577,523. Filed Dec. 12, 1894.

Consists in first freeing the air from carbon dioxid and then drying it, then ozonizing the oxygen of the air into ozone and ozonizing simultaneously the nitrogen of the same into nitrous oxids by electrical currents of high tension in an ozone generator and then separating the nitrous oxids from the ozone by absorbing them in suitable liquids.

APPARATUS FOR PRODUCING OZONE. E. Andreoli, London, England, 577,636. Filed Aug. 12, 1896.

Details of construction.

ELECTRIC ELEVATOR. J. P. Casey, Philadelphia, Pa., 577,644. Filed June 13, 1893.

Automatic means for shutting off the current when the lifting cable is impaired.

APPARATUS FOR PRODUCING ELECTRIC CURRENTS OF HIGH FREQUENCY. N. Tesla, New York, 577,670. Filed Sept. 3, 1896.

For description see page 239.

MANUFACTURE OF ELECTRICAL CONDENSERS, COILS, ETC. N. Tesla, New York, 577,671. Filed Nov. 5, 1896.

Exhausts the air from the insulation while hot, and then admits compressed air after the material begins to cool and solidify.

TOY. L. A. Eberhardt, New York, 577,730. Filed July 9, 1896.

Composed of a base-plate, a superposed horseshoe magnet and a metallic object adapted to be moved along the base-plate and between the magnet shanks.

SAFETY DEVICE FOR ELEVATORS. W. Ehrhardt, Union, Hudson County, N. J., 577,649. Filed Jan. 4, 1895.

Locking devices on the door of shaft whereby the door is held locked until released by a contact device on the car.

COMBINED CHECK-RECEPTACLE AND CASH DRAWER. A. R. Miranda, Boston, Mass., 577,533. Filed Nov. 27, 1896.

Details of construction.

Railways and Appliances:—

ELECTRIC RAILWAY SYSTEM. C. F. De Redon, New York, 577,450. Filed Sept. 5, 1895.

Includes a circuit closer comprising a permanent magnet adapted to be attracted by a part carried by the car, a lever on which the magnet is placed, a contact plate carried by the plate and having connection with the current carrying wires.

ELECTRO-PNEUMATIC BRAKE. F. Chapsal, Paris, France, 577,526. Filed Sept. 26, 1896.

Combines a pneumatic brake system, an electrically operated brake valve therefor, comprising an oscillating electromagnet, a single line wire leading thereto, and means for sending reverse currents over the wire, and valves operated by the oscillation of the magnet.

TROLLEY FOR ELECTRIC RAILWAYS. H. N. Gale, Bristol, Conn., 577,741. Filed Oct. 16, 1896.

The wheel is mounted so as to permit of a lateral motion.

ELECTRIC AND GRAVITY PLEASURE RAILWAY. J. A. Griffiths, Philadelphia, Pa., 577,550. Filed April 3, 1896.

Comprises a car provided with a downwardly projecting feeder-arm, a trough arranged along the course below the surface and a feeder wire arranged in the trough only at the upwardly inclined portions of the course.

Switches, Cut-Outs, Etc.

AUTOMATIC CIRCUIT BREAKER. G. F. Packard, Fort Wayne, Ind., 577,447. Filed Sept. 22, 1986.

Employs a weighted drop-armature adapted to break the circuit upon a predetermined increase of the current in the main circuit.

ELECTRIC CUT-OUT. J. F. McElroy, Albany, N. Y., 577,822. Filed Oct. 20, 1894.

Consists of a porcelain block, a curved grooved channel-way therein, a curved fuse-wire placed in the channel-way, suitably connected with a flexible covering over the channel.

Telegraphs:

SUBMARINE TELEGRAPHY. A. Muirhead, London, England, 577,534. Filed Nov. 18, 1895.

Method of transmitting impulses by means of perforations in strips of paper.

TELEGRAPH TRANSMITTER. H. A. Taylor, London, England, 577,540. Filed Nov. 18, 1895.

Similar to above.

PERSONAL

MR. A. D. WIKE, secretary of the Marietta, Pa., Electric Light Company, and prominently connected with other Marietta enterprises, died on February 24 of pneumonia, at the age of 52.

MR. D. PADDOCK, assistant electrician of the "Big Four" Railroad, has resigned in order to engage in electrical work in Chicago.

MR. H. T. SIMPSON has been appointed superintendent of telegraph on the Chesapeake & Ohio Railroad to succeed the late M. B. Leonard.

MR. G. H. LEWARS, assistant treasurer of the Westinghouse Electric and Manufacturing Company, and formerly in a like capacity with the Sawyer-Man Company, has resigned in order to accept the position of general manager with the Curtis Publishing Company, of Philadelphia, which issues the popular Ladies' Home Journal.

T. A. EDISON, JR., has been in Texas recently making arrangements for the introduction of his father's phonoplex on the Santa Fé Railroad system.

DR. S. S. WHEELER, president of the Crocker-Wheeler Electric Company, leaves for Bermuda to-day, and will be gone about three weeks.

MR. C. S. KNIGHT, Mr. J. J. Wood and Mr. W. J. Buckley, of the Fort Wayne Electric Corporation, have been making a study of all the new work at Niagara Falls the last week.

MR. CHARLES A. VALLETTE, cashier of the Missouri Electric Light and Power Company, St. Louis, and secretary and treasurer of the Edwardsville (Ill.) Electric Light and Power Company, was a Chicago visitor last week and made a call at the office of The Electrical Engineer. He reports the outlook good for larger business.

THE STOCK MARKET

WAITING BUT HOPEFUL.

The course of industrial and financial events appears to be steadily for the better. The improvement in the value of securities is not large, but it seems to be secure. An opinion appears to be current that a marked gain will follow the inauguration of Mr. McKinley, but there is no solid reason offered for this, as the controlling conditions remain unchanged. The boom that comes in the spring may, however, hasten its arrival, especially as the balance of trade still runs strongly in our favor.

On the stock market, the talk is bullish in many directions, but there is no great activity. Of Western Union during the week, 5,699 shares were sold, opening at 82¼ and closing at 83½. General Electric on sales of 11,190 shares advanced from 34½ to 35. In Boston, American Bell held its own, and looks good for 230. The general status of local lighting and railway stocks and bonds has also improved and there is a brisker inquiry. The public is slowly but steadily absorbing good bonds.

LEGAL NOTES

TELEGRAPHIC MISDEMEANORS.

The U. S. House of Representatives Committee on the Judiciary has favorably reported a bill which makes it a misdemeanor for any person to transmit by any telegraph or telephone company any dispatch from any State or Territory relating to lotteries, poolselling, bookmaking, or gambling.

DAMAGES FOR TELEGRAPHER'S BULLS.

The Kentucky Court of Appeals, in an opinion by Judge Guffy, delivered against the Western Union, holds that telegraph companies are liable for damages for mistakes in unrepeated messages, notwithstanding the waiver of damages printed on the backs of the company's blanks.

MARSDEN J. PERRY AS UNITED TELEGRAPH CO.'S RECEIVER.

At Boston, on February 24, in the United States Circuit Court a hearing was given in the United Telegraph Company receivership case, resulting in the removal of H. J. Pettingill as receiver and the appointment instead of Marsden J. Perry of Providence, R. I. The change in the receivership was made on the petition of the defendants, who claimed that Mr. Pettingill, being superintendent of the Postal Telegraph Company, a competitor, was hostile to their interests.

Judge Colt, in making the order, said that he made the change as it was the ordinary procedure when one of the parties objected to the receiver. An order of notice was issued, returnable on March 9, when a further hearing on the injunction will be held. Mr. Perry was given five days in which to file a bond of $20,000.

PLAN FOR THE BETTER LOCATION OF KEY HOLES.

The New York Aldermanic Committee on Streets gave a public hearing last week on the subject of illuminated house numbers. Mrs. Helen N. Gaillard, of Brooklyn, exhibited for the enlightenment of the committee members a portion of a hall door, to which was attached an electric appliance, by means of which the numbers on a frosted glass plate let into the door were illuminated. The light came from a tiny incandescent lamp, the current for which was supplied by a small two-cell battery. Mrs. Gaillard said that the contrivance could be applied to keyholes as well as to numbers. The committee will report at the next meeting of the Aldermen.

BOARD OF CONTROL. Senator Stranahan has introduced in the State Senate a bill extending the life of the New York Board of Electrical Control for one year from November 1, the salary of the commissioners to be $5,000.

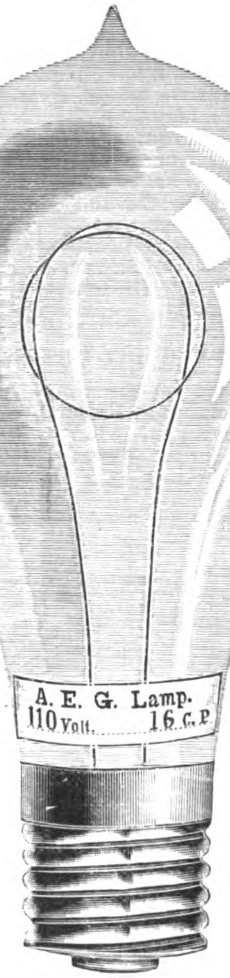
⁂

TRADE NOTES & NOVELTIES

THE A. E. G. INCANDESCENT LAMP.

THE cut herewith is the same size as the standard 16 candle-power lamp made by the Allgemeine Elektricitats Gesellschaft of Berlin, Germany, for the American market. This concern, which is the largest in Europe, first started as a lamp factory alone. This was back in 1883, and the success that this line of their goods obtained was an entering wedge for the enormous volume and variety of business that they are now doing in all quarters of the globe.

Until now the demand for their lamps in Europe, and, in fact, the whole Eastern hemisphere, has been so great that the total product was absorbed there. Recently, however, their factories have been enlarged, and they are now placing their goods on the market in this country, being convinced that their superior quality will make them exceedingly popular.



A. E. G. Lamp.
110 Volt. 16 C.P.

STANDARD A. E. G. LAMP.

The lamp filaments are made by a secret process which insures exceptional durability and maintenance of candle power. Numerous tests that have been made justify them in giving a guarantee of an average life of 800 hours for the standard 16 candle-power lamps and even this is far below the results obtained.

The lamp is very graceful and has several mechanical features which will commend themselves to the practical man. The bases are made of spun brass and porcelain, and are secured to the lamps themselves by a very small quantity of special cement, which is almost perfectly moisture proof. Twisting off of the bases is unknown.

Messrs. Machado & Roller, 203 Broadway, New York City, have been appointed the sole agents for the United States for these lamps and will gladly send their lamp book and prices to interested parties, a category which includes every lamp consumer in the United States.

THE INCANDESCENT LAMP SITUATION.

With reference to the information on this subject in our pages last week, we are in receipt of the subjoined confirmatory data from the Westinghouse Electric and Manufacturing Company, or, rather, its alter ego, the Sawyer-Man Co., which conducts that part of its business:

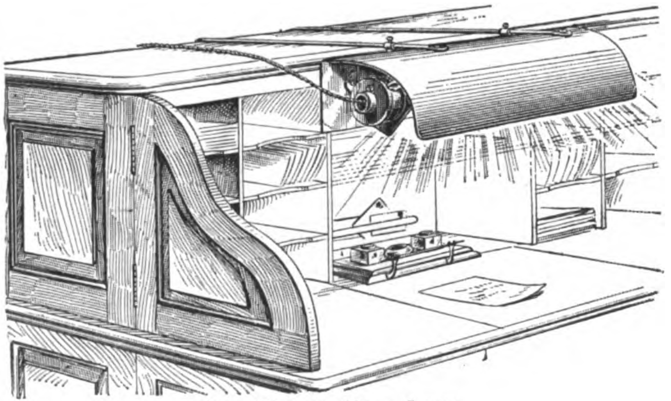
The Westinghouse Company is the owner of a large number of patents relating to incandescent lamps and the processes of manufacturing them.

The following companies have been granted licenses by the Westinghouse Company, and are now operating under these patents, viz.: Bryan-Marsh Company, the Perkins Electric Switch Manufacturing Company, the Columbia Incandescent Lamp Company, the Buckeye Electric Company, the Sunbeam Incandescent Lamp Company, the Adams-Bagnall Electric Company, General Electric Company, New York and Ohio Company.

It is further understood that the Westinghouse Company is prepared to grant licenses upon equitable terms to other reputable manufacturers of incandescent lamps, and that several are now negotiating for them. Newspaper statements have appeared from time to time to the effect that a pool has been formed among certain lamp manufacturers. The officials of both the Westinghouse and Sawyer-Man Companies state that they are not members of any such pool, but are continuing the independent manufacture and sale of incandescent electric lamps. Other rumors to the effect that the Westinghouse Company has gone entirely out of the incandescent lamp business are denied by the officials. This rumor may have arisen from the fact that the Westinghouse Company does not itself manufacture incandescent lamps, having about a year ago reorganized the Sawyer-Man Company, one of its controlled companies and transferred its incandescent lamp business to that company.

THE DAYLIGHT DESK LAMP.

E. J. WARING, 136 Liberty street, New York, is enjoying great success with his "Daylight" electric desk lamp, of which the accompanying cut will give the reader a good idea. This electric desk lamp is constructed upon scientific principles, and is of value to those who are compelled to do night or dark desk work. The light is soft and abundant, and so well distributed as to leave no shadows or dark corners on the desk; yet the lamp itself is entirely shaded from the eyes. Furthermore, it does not heat the head. In appearance it is ornamental and attractive, and in no way interferes with the opening or closing of a "roll top" desk. With upright mountings it is well suited to "flat top" desks or "library tables," being especially suitable for a library or reading lamp.



The Waring Desk Lamp.

Catalogue and price list will be cheerfully mailed to any address on application.

A BIG SHELBY INCANDESCENT LAMP DEAL CLOSED IN THE WEST.

Jas. C. Wormley & Co., whose general offices are in the Marquette Building, Chicago, closed a deal some time ago with the Shelby Electric Company, of Shelby, Ohio, whereby they are to have the sole agency for the Shelby tipless lamp in Cook County, Illinois, and Minnesota. We understand that the contract was made some time ago, but only recently became public.

It is Mr. Wormley's intention to carry a large stock of the Shelby lamps in Chicago as well as in St. Paul, where his company has a well established agency. Mr. Wormley has been connected with the incandescent lamp business for several years and is one of the largest exclusive dealers in that line in the United States.

Mr. Wormley was up to the time that the Universal Electric Company's factory was destroyed by fire, their sole agent for the West, and it was with that lamp that he built up his reputation with the trade. Since the Universal was burned out of existence he has had several different factories manufacture for him. As Mr. Joseph Hardwick, formerly superintendent of the Universal factory, is now connected with the Shelby Electric Company, he feels that he is in a position once more to hand his old customers a lamp manufactured after his own ideas.

In addition to the Shelby agency, Jas. C. Wormley & Co., will continue to market the Wormley lamp in all territory. This lamp is made up in lower efficiency than the Shelby lamp, running from 3 to 4 watts per candle power, but has a double coiled filament (showing 2 turns). It may be said since they commenced advertising this lamp at a discount that it has become very popular, both in the East and West.

THE CHICAGO SCHOOL OF ELECTRICITY.

Messrs. W. Clyde Jones, A. Scheible and E. J. Swartout, a special committee of the Chicago Electrical Association, have investigated the Chicago School of Electricity, and report favorably upon its aims and work.

BRYANT CATALOGUE SUPPLEMENT.

The Electric Appliance Company have just prepared a supplement to the Bryant catalogue of electrical specialties, showing a line of the best electric light specialties that have been brought out during the past year. The supplement is also supplied with a special trade discount sheet giving trade prices on the goods listed. The Bryant specialties have a great reputation, and anything new brought out by this company is always received with considerable interest. The Electric Appliance Company would be glad to send one of these catalogues with discount sheet to the trade, on application.

THE JUNGFRAU ELECTRIC RAILWAY.

M. Guyer-Zeller, chairman of the Jungfrau Electric Railway Syndicate, Zurich, informs us that it is proposed to finance the undertaking before Easter, and one-quarter of the whole capital is to be reserved for English and American subscribers. The prospectus of the company, giving details of the technical and financial considerations, has been issued in the English language. Our readers will recall the description of this remarkable undertaking appearing in our issue of Nov. 18, 1896. The lowest section of the road as far as the Eiger glacier is to be completed during the coming summer.

ELECTRIC MINE HAULAGE PLANT AT MOON RUN, PA.

The Moon Run Coal Company, of Moon Run, Pa., is about to install an electric haulage plant in its colliery, and to this end has contracted with the General Electric Company for electrical equipment, sufficient to operate a mine road with over three and one-half miles of tracks. The generating station will consist of one 165 k. w., 250-volt generator, directly connected to a Harrisburg Ideal Engine 18½ inches by 16 inches. These with the switchboard will be set up in the present power house, which at present contains an air compressor plant for the operation of certain pick machines. The inside haulage will be handled by one 10-ton mining locomotive, equipped with 40 horse-power motors. This will haul 40 loaded cars per trip, each loaded car weighing about two and a half tons. There will be over three and one-half miles of trolley wire in the mines, with the necessary feeders.

It is worthy of note that electricity was not adopted by the Moon Run Coal Company before it had made a more than careful investigation of the merits of all other systems of mechanical haulage, cable, compressed air and steam. The economical showing exemplified by the results obtained in the many other mines now using the General Electric Company's system of electric haulage, proved conclusively the advantage which would accrue to the Moon Run Colliery by the introduction of electricity.

BUILDINGS FOR SALE.—Some four years ago, the Berlin Iron Bridge Company, of East Berlin, Conn., designed and built a stove works at Sioux City, Iowa. Owing to the failure of the company, they have been obliged to take back the foundry building, mounting shop, and general machine shop, and now offer these buildings, which were of the best iron construction, for sale at a bargain. The buildings are not second hand, except the fact that they have been put up once, as they were never used. Here is an opportunity for any company contemplating new construction to examine into the matter, as the price at which these buildings are offered is much below the present market value of all classes of structural material. See their ad. in another column.

ADVERTISERS' HINTS

THE INTERIOR CONDUIT AND INSULATION COMPANY, announce that their new styles of fan motors are now ready.

THE GLOBE ELECTRIC HEATING COMPANY, 141 North 12th street, Philadelphia, are again advertising their heaters which they are so successfully manufacturing for a large variety of uses.

THE GOODYEAR VULCANITE COMPANY, 353 Broadway, New York, are supplying hard rubber goods for electrical and mechanical purposes, including phonograph tubes, hook insulators, magnet heads, battery cells, sounder covers, etc.

A. L. BOGART, 22 Union Square, New York, are making the Bartholdi automatic gas lighter which they claim to be the smallest in use. This is but one article in a long line.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY state they have constructed 26,000 horsepower in oil-insulated transformers at potentials ranging from 5,000 to 50,000 volts.

THE STANDARD AIR-BRAKE COMPANY, 100 Broadway, New York, guarantee to control any car by means of their apparatus on any grade up to 13½ per cent., and for even steeper grades they have special equipments to meet the most extraordinary difficulties.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, have just issued a supplement to the Bryant catalogue which they will send on application with a special trade discount sheet.

THE BALL ENGINE COMPANY, Erie, Pa., publish a list of medals awarded to them for the excellence of their automatic engines.

EDWARDS & CO., 144th street and Fourth avenue, New York, say the "Eco" buzzers and bells never work out of adjustment. They are provided with platinized contacts and are dust and bug proof.

MACHADO & ROLLER, 203 Broadway, New York, are the sole American agents for the "A. E. G." incandescent lamps.

WM. SMITH HORRY, Sault Ste. Marie, Mich., and Ontario, will undertake the design of electrical machinery of all kinds.

THE McFELL ELECTRIC COMPANY, Marquette Building, Chicago, Ill., are now the Western agents for Whitman & Couch, the importers of the Ericsson Swedish Microphone.

EDWARD M. BENTLEY, Temple Court, New York, will be glad to correspond with those who may desire the services of an expert in patent cases.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., have secured the order for the entire engine equipment of the new station of the Scranton Illuminating, Heat and Power Company, consisting of five cross compound engines and one simple engine.

BROWNLEE & CO., Detroit, Mich., advertise "a perfect pole" for which they claim strength, durability and economy.

THE WARD LEONARD ELECTRIC COMPANY, Hoboken, N. J., will this week introduce their automatic under and over load circuit breaker which they state is a strictly high grade article with a capacity of 30 amperes. The price during March is $7.50 net.

THE HUNTER FAN AND MOTOR COMPANY, Fulton, N. Y., are now ready with the '97 patterns of the Tuerk alternating current ceiling Fan made for from 50 to 120 volts and finished in various styles.

THE WALKER COMPANY, Cleveland, Ohio, advocate the use of their trolley which cannot leave the wire, and with which a switch may be dispensed with.

THE BERLIN IRON BRIDGE COMPANY, East Berlin, Conn., are offering an iron building for sale at a bargain. It is adapted for a foundry, machine shop and, with very slight alterations, for a cow barn.

THE H. B. CAMP CO., Aultman, Ohio, say they are quite able to convince interested parties of the superiority of their vitrified clay conduits for underground wiring.

THOS. MUIR & SON, 31 Larned street, W., Detroit, Mich., have brought out a new automatic motor starter for 110, 220 and 500 volts circuits. Among its good points may be noted its simplicity, reliability and safety, only one being required to control a 500-volt current.

THE AUTOMATIC CIRCUIT BREAKER COMPANY, Newaygo, Mich., guarantee their circuit breakers to operate perfectly or no pay.

THE AUTOMATIC SWITCH COMPANY, Equitable Building, Baltimore, Md., are now ready to furnish the latest type of the Whittingham automatic motor starter for pump elevator and other motors, and also their quick acting switch. They say they prevent accidents and save money.

UEHLING STEINBART & CO., LTD., 60 Mulberry street, Newark, N. J., say that thousands of tons of fuel now wasted by bad firing, can be saved by the use of the gas composimeter which indicates and records continuously the percentage of carbon dioxide in the chimney gases, making an autographic record of the condition of the fire. Write them for details.

THE MENOMINEE ELECTRIC AND MACHINE COMPANY, Menominee, Mich., make a specialty of fan motors.

CARLISLE & FINCH are manufacturing search lights for a variety of uses.

THE AHLM-EDWARDS ELECTRIC COMPANY, Medina, Ohio, build their motors with adjustable bases which adapts them for fastening to ceilings and walls where floor space is at a premium.

NEW YORK NOTES.

THE BERGMANN LONG-LIFE ARC LAMPS are the subject of a handsome catalogue just issued by the General Incandescent Arc Light Company, 572-578 First avenue, New York City. The styles for 1897 are illustrated and described and prices are quoted. These enclosed arc lamps are shown up in careful detail, and many valuable points are given as to their use by lighting companies and purchasers. Some data is also given as to "Sun-Schmelzer-Nuernberg" carbons for direct current enclosed arc lamps. The company are manufacturers of various styles of arc lamps, blade switches, switchboards, etc., and stand ready to undertake general and experimental work of all kinds. A view of the fine factory is shown on the last page.

MR. M. R. RODRIGUES, 17-19 Whipple street, Brooklyn, manufacturing electrician, is in the market for a quantity of small steel castings, and will be glad to hear from any foundry making a specialty of them.

A. L. BOGART, 22 Union Square, New York, will soon issue a new and complete catalogue of his electric gas lighting attachments. It will dwell especially on the attachments as applied to the Welsbach light. The catalogue will be the first of its kind ever issued and, as stated by Mr. Bogart, will be of great value to those interested.

MR. L. J. McPARLIN, a lawyer of Lockport, N. Y., has secured the signatures of 150 firms and individuals to a 5 years' contract for telephone service, at $30 a year for business places and $24 for residences. The new company propose to issue about $8,000 of bonds, for ten years, at 6 per cent., and will be glad to hear of parties who will place this amount for them.

THE ELECTRICAL MERCANTILE AGENCY, of 318 Broadway, New York, has issued a very neat slip pad calendar for 1897 to its friends and patrons, who find it quite an ornament for their desks. The agency has published also a neat little brochure describing the features of its admirable work for the protection of credit and the sifting out of irresponsible parties.

THE PELTON WATER WHEEL COMPANY, San Francisco and New York, have recently shipped a number of wheels to Japan; also three wheel plants to the Island of Java, East Indies, including pipe lines and all appliances. The former were chiefly for electric lighting, and the latter for running the machinery of sugar, tea and coffee plantations, as well as for furnishing light. The company are using as a very interesting letter circular a picture of the surveying work being done by one of their engineers and a gang of native assistants, for a large power station in the Malay Peninsula, not far from Singapore. This plant will furnish power and light for several large towns, over transmission lines.

JOHN SIMMONS COMPANY, 106 Centre street, New York, are pushing the sale of their two specialties, the Excelsior railway bracket, one of the best brackets now on the market suitable for trolley roads, etc., and their Hercules switchboard. Business is brisk in all their departments. John Simmons Company carry an immense stock constantly on hand of wrought iron pipe fittings, valves and supplies for steam, gas water and electrical engineering.

KEUFFEL & ESSER COMPANY, 127 Fulton street, New York, report a good trade for their drawing materials, etc. The electrical industries make up a good share of the trade controlled by this firm, and the renewed activity is causing plenty of work to be put on tracing paper, at least.

FRED'K RECKENZAUN, 44 Pine street, New York, consulting and contracting engineer, installed the storage battery fire alarm plant for the city of Rochester, N. Y., the largest of its kind in the country. Mr. Reckenzaun is ready to undertake other installations of this character.

M. E. SANGER & CO., 36 Cortlandt street, New York, are manufacturing intricate and special devices for a number of electrical companies. They do also experimental and model work, and will be glad to hear from any parties desiring such work.

THE AMERICAN ENGINE CO., Bound Brook, N. J., have just secured the order for the entire engine equipment of the new station of the Scranton Illuminating, Heat and Power Company, to be built on the site of the old station recently destroyed by fire. The equipment will consist of six American-Ball engines, five of which will be compound and one simple. Direct connected generators will be used on four of these engines, and the station will be modern in all its appointments.

THE STANDARD AIR-BRAKE COMPANIY has secured the services of Mr. Herbert B. Taylor, at present with the Consolidated Traction Company, as chief assistant in the electrical department to Mr. F. Ubelacker. Mr. Taylor has handed in his resignation and will enter the service of the Standard Air-Brake Company on March 1.

NEW ENGLAND NOTES

BIBBER, WHITE & CO., of Boston, are the manufacturers of the Boston transformer, whose economy is in keeping with the saving principles that are well recognized at the Hub, and exemplifies New England thrift. The company will be glad to receive and answer inquiries on the subject.

THE SWETT & LEWIS COMPANY, successors to G. A. Frei & Co., of 17 Bromfield street, Boston, manufacturers of X-ray supplies, have just moved to 11 Bromfield street, the old quarters being too small to accommodate the ever increasing business. They have more than doubled their space, as well as force of employés. All their tubes are made in their own laboratories by skillful glass-blowers. The fluoroscopes are neatly gotten up, and the screens coated by a process entirely their own. Besides a laboratory and office, they have fitted up a large dark room for photographic purposes, also an operating room, so that a physician can bring in a patient, and have a radiograph taken in entire privacy. We understand that they are soon to bring out a new style of tube, which will have many points of excellence.

WATER WHEEL GOVERNORS FOR MINNEAPOLIS.—The Lombard Water Wheel Governor Company, of Boston, have closed a contract with the St. Anthony Falls Water Power Company, of Minneapolis, for seven governors for the new plant which they are building. These seven governors are to regulate four water wheels each, or 28 water wheels in all, aggregating 10,000 horse-power. The style of governor to be employed in this plant is designated by the manufacturers as Type C. During the past year the Lombard Company have with this governor regulated over 40,000 horse-power of water wheels, in the United States. On account of the magnitude of the Minneapolis plant, the question of governors was very carefully looked into before the above order was placed.

WESTERN NOTES

TRIUMPH ELECTRIC COMPANY, of Cincinnati, O., have issued a very striking list of their sales of multipolar and bipolar machines sold during 1896. This apparatus was installed all over the country in large and small plants, and for a great variety of purposes. They will be glad to receive inquiries as to any projected new work.

MR. G. D. STURTEVANT, of the Adams-Bagnall Electric Co., Cleveland, paid a visit to Chicago recently and had his headquarters at their branch office. He was taken good care of there by Mr. J. G. Pomeroy. Mr. Sturtevant was fortunate enough to secure an order recently from the city of Newark, Ohio, for 100 of their differential arc lamps.

THE METROPOLITAN ELECTRIC COMPANY of Chicago have taken the agency of the Reynolds self-insulating bug cut-out, and have a stock of these on hand, from which they can make prompt shipments. This cut-out is a new one which has some very desirable features. It consists of two pieces of porcelain so recessed and put together as to entirely cover and connect the fuse wire and connections. It is neat and compact in form, and the size is only about ¾ inch in diameter by 1½ inch long. This, with the other desirable features, makes it a cut-out which will fill many requirements of the wiring trade.

H. M. UNDERWOOD & CO., 204 Dearborn street, Chicago, have been appointed general Western agents for the sale of the Adjustable Shade Holder, manufactured by the Housatonic Company, of Wellingford, Conn., who are to be congratulated on having secured the services of so able a representative as Mr. Underwood, who is most energetic and has a large acquaintance amongst the electrical trade in the West.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, which is the new style of the Card Electric Motor and Dynamo Company, as noted in our columns last week, is making some important changes in the handling of its Eastern business. This part will be in the hands of the Bullock Electric Company, which will control the sales east of the Alleghanies, and which opens offices this week in the new St. Paul Building, Broadway and Ann streets. Preparations have been made to handle business double that of last year.

ELECTRIC LIGHTING

THE BOWLING GREEN STORAGE BATTERY STATION OF THE NEW YORK EDISON CO.

THE Edison Electric Illuminating Co., of New York, was from the very beginning of its existence, a pioneer in low tension central station distribution, and since 1882 has led the way in the adoption of most of the methods and apparatus which have served to keep this system of distribution so well abreast of the times.

Ever on the alert to call to its aid the latest advances in the art the company long since undertook an investigation into the advisability of adding storage batteries to the existing system, with the result, that a battery was installed in the company's Fifty-third street station. This was in 1890, and the experience gained since then led to the installation of a battery of greatly increased size in the new Twelfth street station, which went into operation during the past year.

Up to this period these batteries had been employed only as auxiliaries to the stations in which they were installed, but the distribution of load on the company's extended system had become such, that it was found that advantages in several directions would accrue by the use of storage batteries used as independent distributors, fed at a distance by current from one of the existing stations of the company.

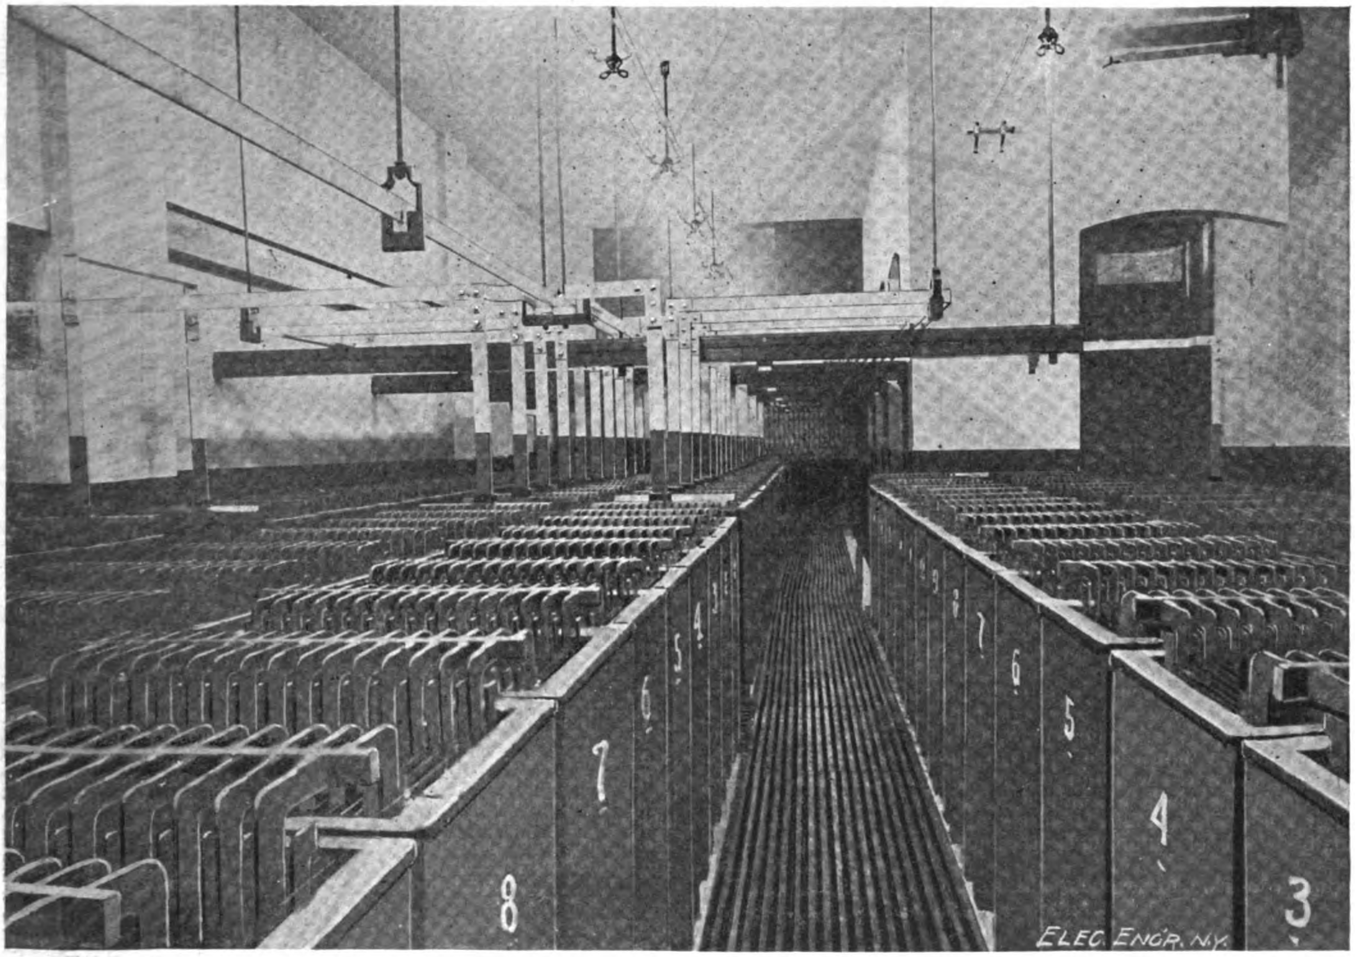

FIG. 1.—BATTERY ROOM, BOWLING GREEN SUB-STATION, EDISON ELECTRIC ILLUMINATING CO., NEW YORK.

Such a storage battery sub-station has now gone into operation, located in the Bowling Green Building, situated close to the southern tip of Manhattan Island.

THE OBJECT OF THE BATTERY STATION.

Before entering into a detailed description of this most interesting installation it may be well to give a short account of the objects for which the battery has been installed and the work it accomplishes.

The new battery plant takes the place of the annex dynamo station formerly situated in the Produce Exchange, and supplies current to a small feeder system, re-enforcing the supply of current from the great Duane street station to the lower part of the district. It furnishes an auxiliary supply of current direct from the battery, enabling the feeders extended as tie feeders into the Bowling Green Building, to be used as distributing feeders to the system from both the Duane street station and the Bowling Green Building. While acting as an auxiliary supply to the general system it also takes care of the distribution of current to the extensive installation of the Bowling Green Building itself.

The supply of current to charge the battery is taken from the Duane street station, about a mile distant, over four-tie feeders, equipped with controllable disconnective switch boxes on the Bowker-Van Vleck system. This enables them to be used as tie feeders by disconnecting them from the general system during the hours of light load, and as distributing feeders during the hours of maximum load, when they feed current into the system from each end. A considerable saving is thus effected in the investment which would be required for costly feeders to supply the maximum load to a distant part of the system.

This installation of an auxiliary source of current supply in

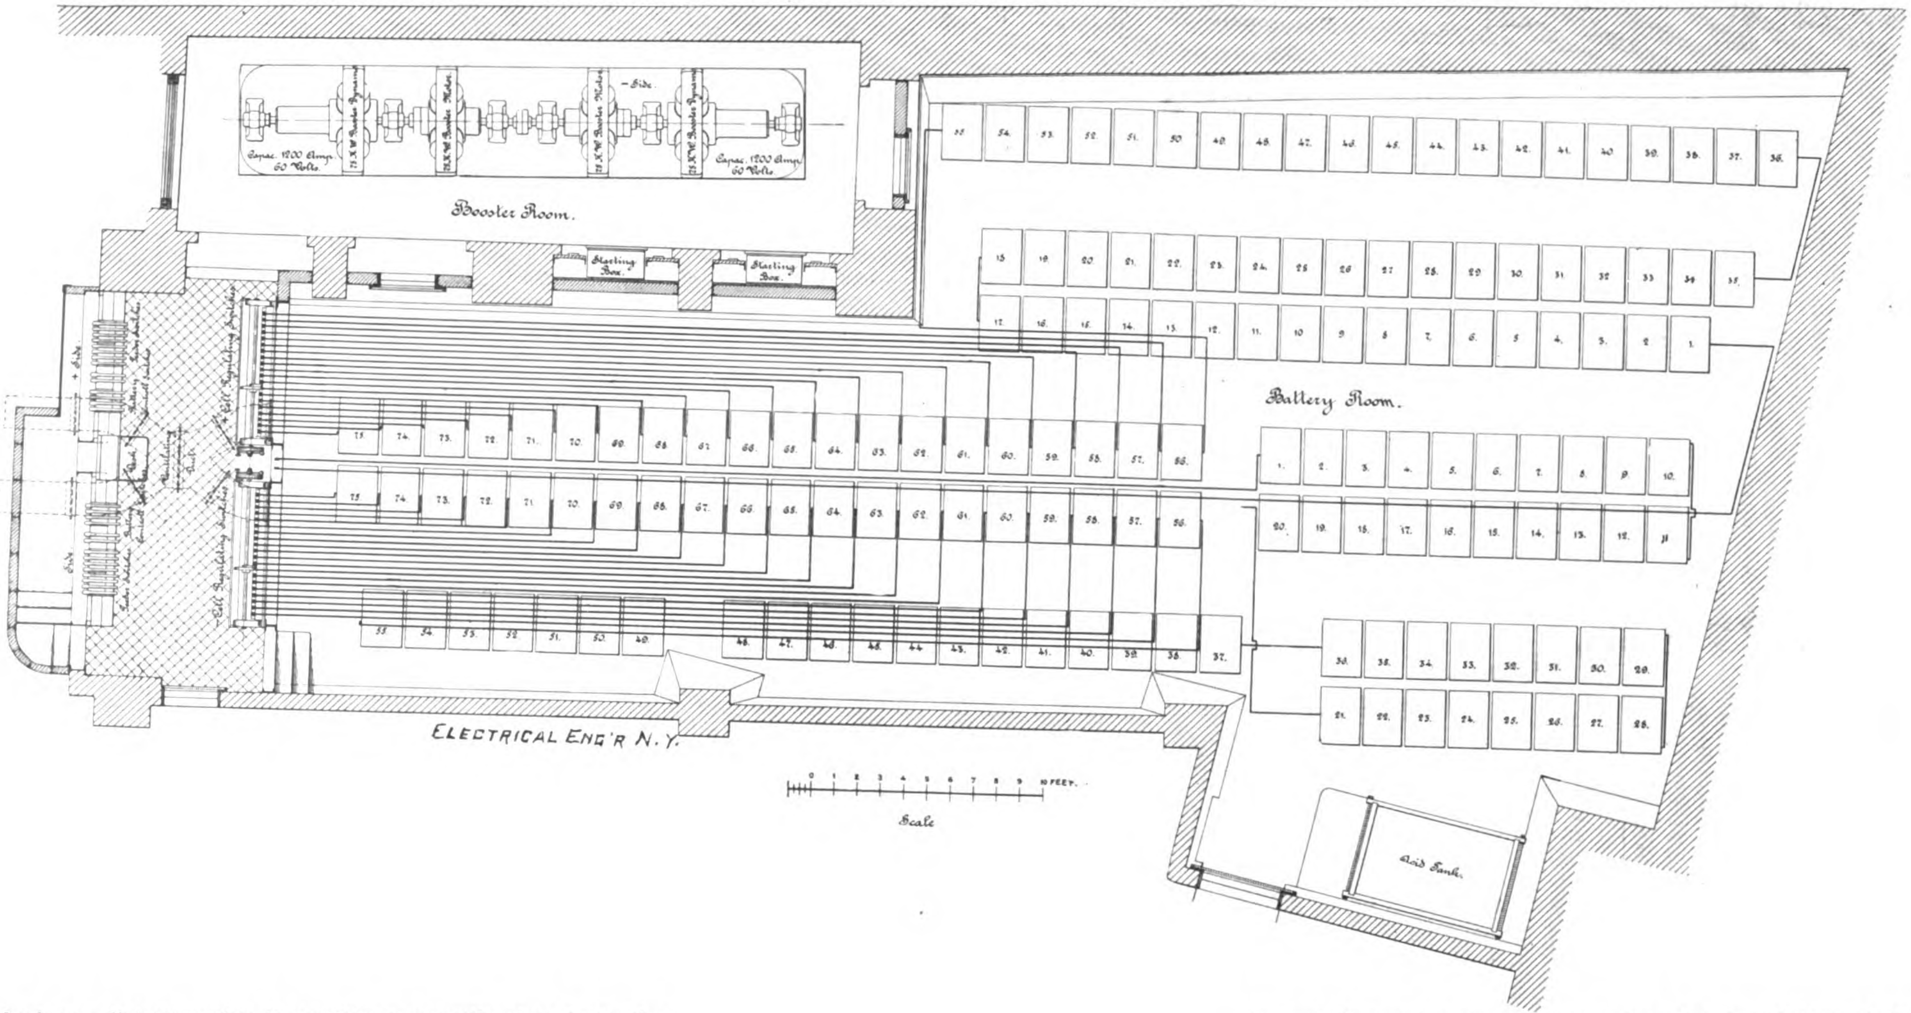

FIG. 2.—BATTERY, BOOSTER AND OPERATING ROOM, BOWLING GREEN STORAGE BATTERY STATION, EDISON ELECTRIC ILLUMINATING CO., NEW YORK.—PLAN VIEW.

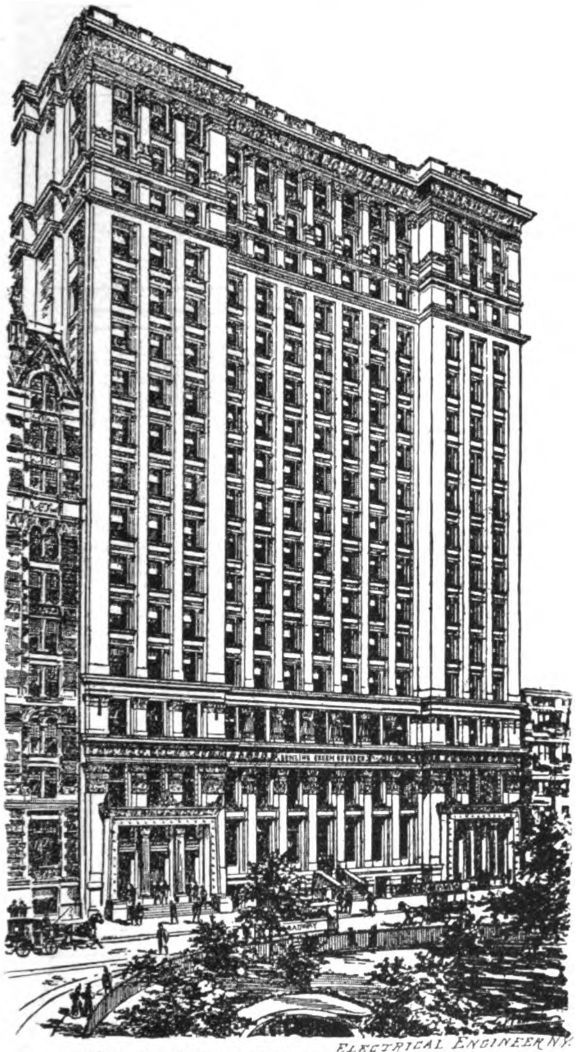
the lower district makes it possible to actually shut down the Duane street station as a generating station during the hours of minimum load, the supply of current to the district below Eighth street being derived from the storage battery plants at Bowling Green and at the Twelfth street station, supplemented, if desired, by the supply of current from the Twenty-sixth street station over the tie lines to the Twelfth street station, whence the current is distributed through boosters, raising it to the required potential, over the tie feeders to the Duane street station switchboard.

By the shutting down of the Duane street station during one watch, while the load is very light in the downtown district, it is expected to effect considerable economy in operation, while providing adequate supply of current from several independent sources.

With this brief account of the raison d'etre of the new battery station, we may now proceed to the description of the station itself, which is noteworthy in more than one particular, representing, as it does, the latest practice in this field.

THE BATTERY ROOM.

The battery room, which is shown in Fig. 1, is located in the sub-basement of the Bowling Green Building, and, due to the fact that the floor of the room is below the water line, an extensive scheme of water-proofing was necessary, and was carried out as follows. See Fig. 4. A layer of concrete, 18 inches thick, was first laid over the entire area, and covered with several layers of pitch and felt. This material was carried out as follows. See Fig. 4. A layer of concrete, 18 this layer of water-proofing, on the floor, were then laid a series of vitrified hollow tiles for conducting the feeder cables under the floor, where they enter at the front of the room, to the rear cable vault under the controlling room, the ducts sloping downward to the rear cable vault. Above these ducts was placed another layer of pitched felt to further prevent any water from rising through the floor, and also, to preclude the possibility of acidulated water finding its way downward into the ducts from the floor above. Another layer of concrete 12 inches thick was then placed above the ducts, and the floor was then covered over with a white vitrified tile, which was found not to be affected by acid and which forms the floor proper of the battery room. This construction is shown in the sectional view, Fig. 5. The water-proofing on the side-walls is retained in place by a wainscoting of slate, securely fastened to the brick walls at the top and imbedded into the concrete at the floor level.



ELECTRICAL ENGINEER N.Y.

FIG. 3.—THE BOWLING GREEN BUILDING.

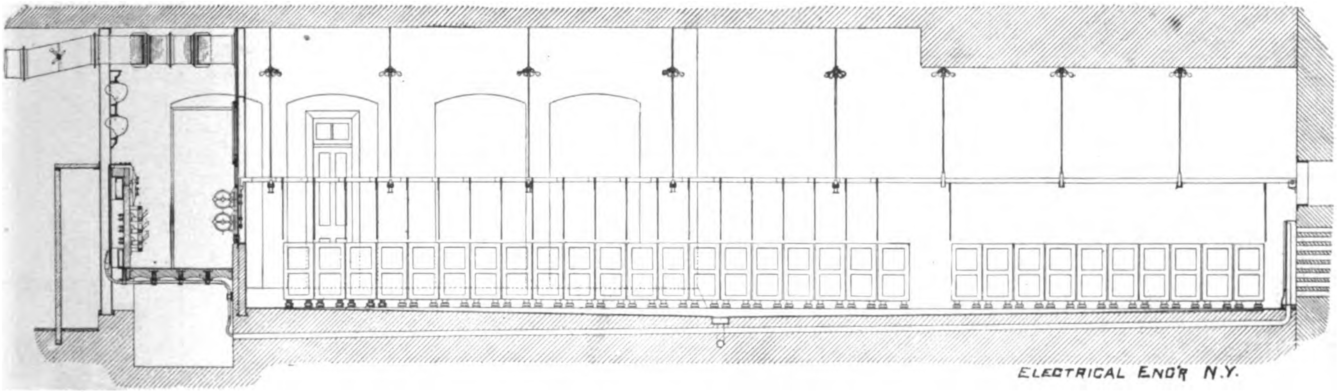


FIG. 5.—BATTERY AND OPERATING ROOM, BOWLING GREEN STORAGE BATTERY STATION. SECTIONAL SIDE VIEW.

It was considered necessary to thoroughly protect the two building columns, which project into the battery room at the south wall, and the base of each column was, therefore, in addition to the usual water-proofing, incased in a boxing of sheet lead one-quarter inch thick. This construction is shown in Fig. 4. Longitudinal drains through the battery room form depressions in the aisles between the battery cells and drain into small cesspools, constructed entirely of lead, which discharge into a 4-inch lead drain pipe, embedded in the floor.

THE BATTERY.

The battery proper consists of 150 cells, manufactured by the Electric Storage Battery Co., of Philadelphia. There are 75 cells on each side of the three-wire system, and each cell contains 14 "Manchester" positive and 15 "chloride" negative plates.

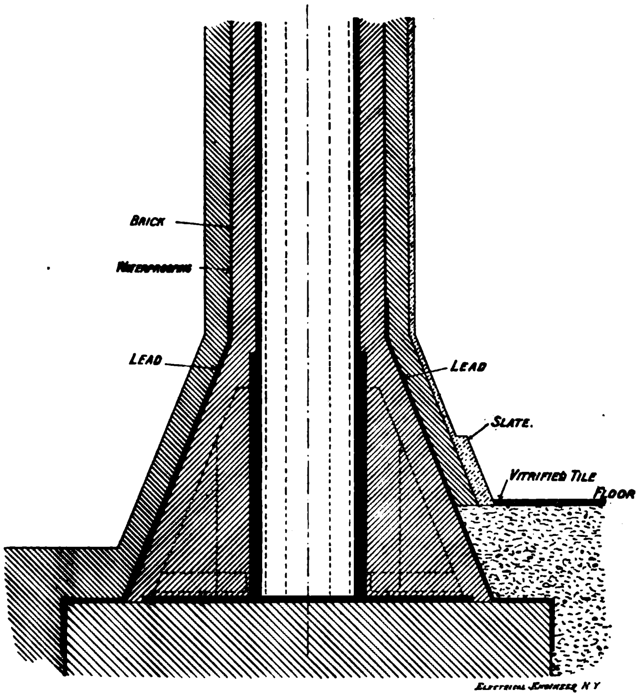

FIG. 4.—SECTION THROUGH BASE OF BUILDING COLUMN.

The guaranteed rate of discharge for one hour is 2,000 amperes per side; for three hours, 1,000 amperes per side, and for ten hours, 400 per side. The normal rate of charge is about 400 amperes per side.

There are 20 regulating cells at the end of the positive and negative sides of the battery series, each of which is separately connected to a block on the regulating switches, shown in detail in Fig. 7. Two regulating switches are connected in multiple on both the positive and negative sides, to permit of a discharge at two potentials, or to enable the battery to be charged and discharged at the same time. This arrangement is shown in Fig. 11. Each cell measures 40¾ inches in height, 21½ inches wide and 30½ inches long. The containing tank is made of poplar, and is lined with lead. Each tank is supported on four special petticoat porcelain insulators, resting on 6-inch vitrified tile.

Provision has been made in the arrangement of the cells to permit of the installation of a duplicate battery which can be placed over the present outfit.

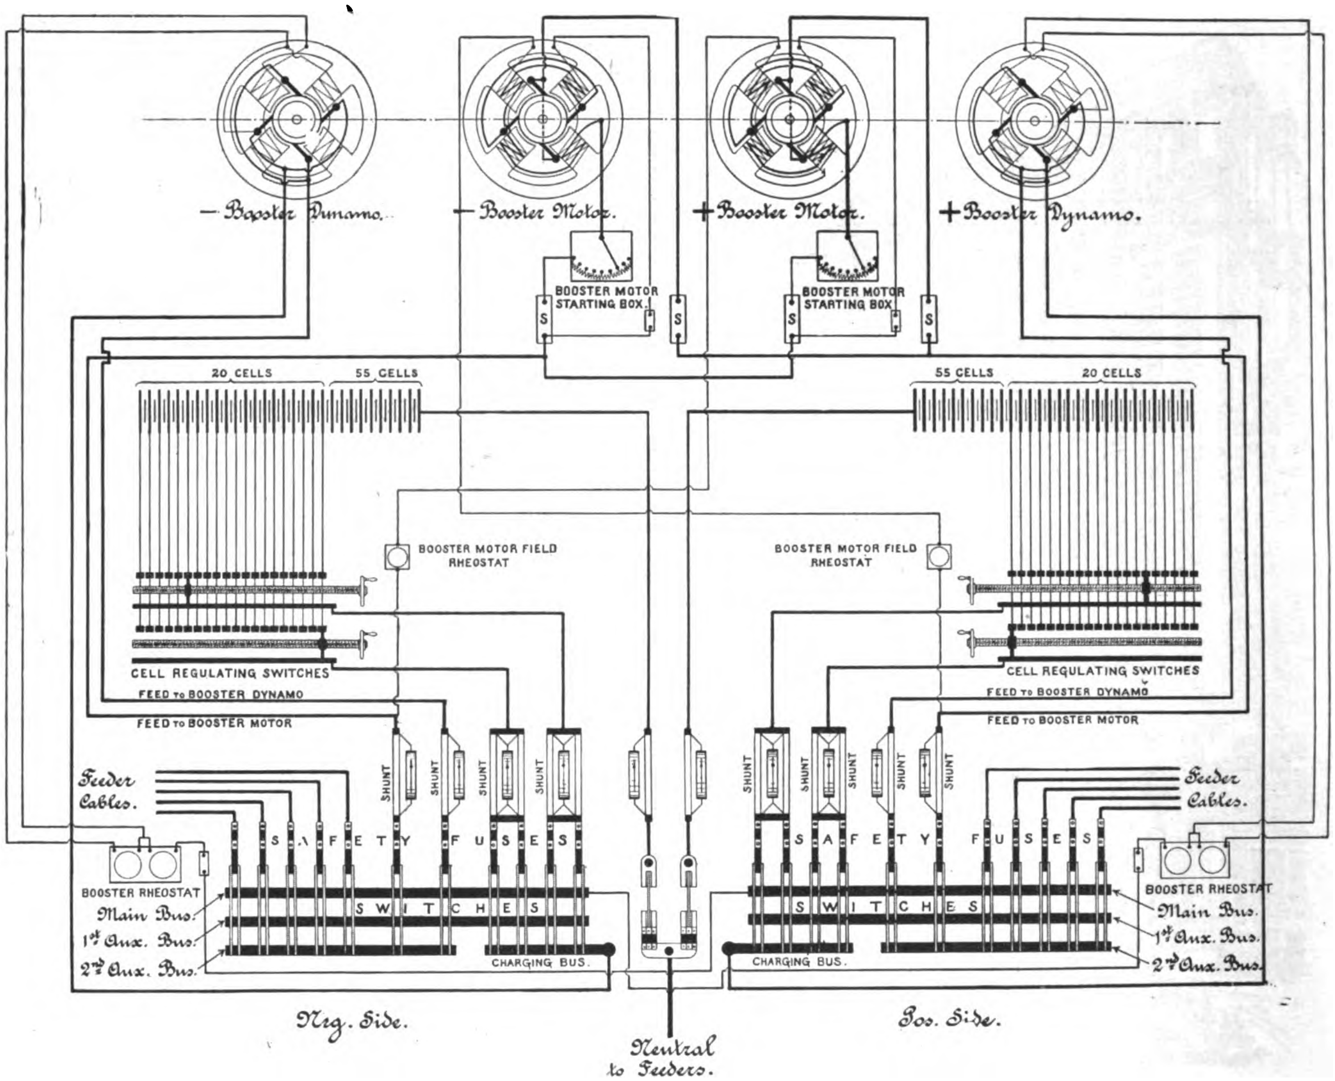

Fig. 6.—Battery, Booster and Feeder Connections, Bowling Green Storage Battery Station.

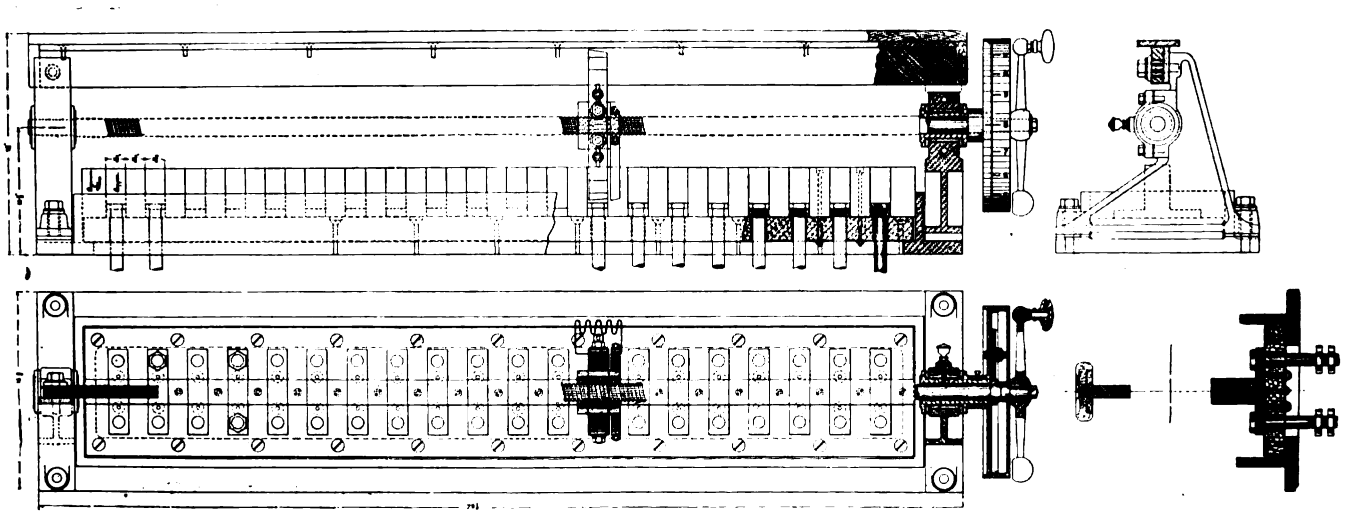

Fig. 7.—Cell-Regulating Switch, Bowling Green Storage Battery Station, New York.

The conductors between each set of cells and between the regulating cells and the cell regulating switches are all made of copper bars three inches wide by one-half inch thick. The area of all the joints is 18 square inches, and each connection is made by two seven-eighth-inch bolts, in preference to the common practice of employing a larger number of smaller bolts. These copper strips are supported on porcelain insulators, resting in hangers, or on horizontal iron beams extending across the room, as shown in the perspective view of the battery room, Fig. 1. The result has been a very symmetrical and substantial arrangement.

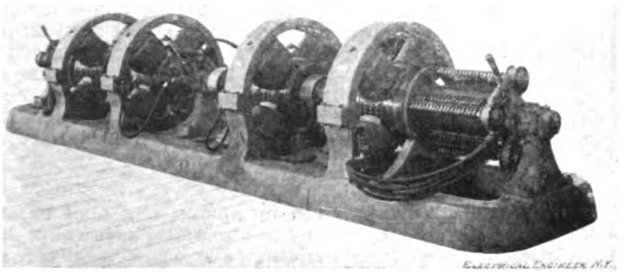

FIG. 8.—BOOSTER IN BOWLING GREEN STORAGE BATTERY STATION.

THE BOOSTER.

In one corner, at the north side, is a space partitioned off from the battery room which contains the booster outfit, with the necessary starting mechanism. The booster illustrated in Fig. 8 and shown on the plan, Fig. 2, is used to raise the e. m. f. of the charging current from the potential of current supplied to the installation to that required for charging the battery. The booster can be used also to raise the e. m. f. of discharge for feeding some distant point of the outside system at a higher initial pressure than would normally be required.

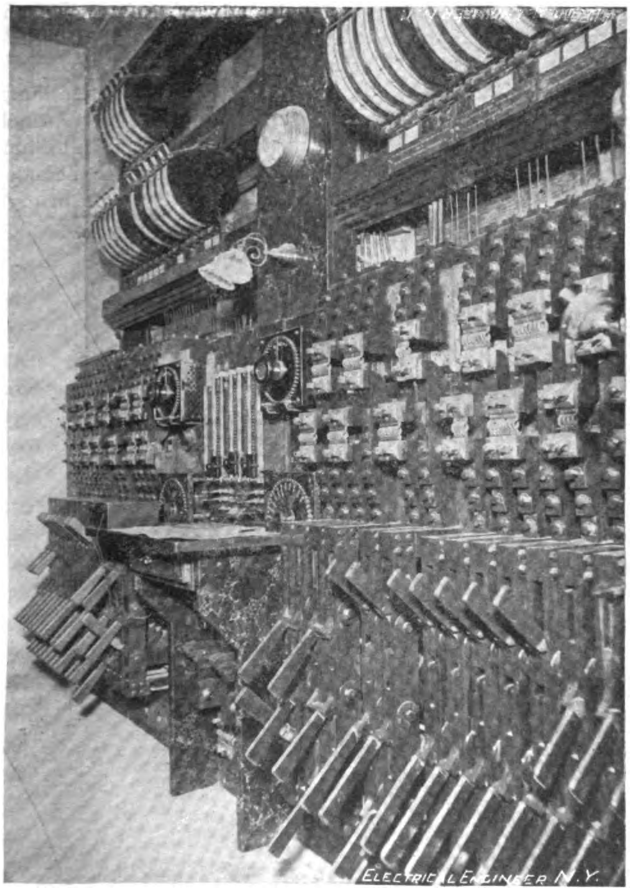

FIG. 9.—BATTERY, BOOSTER AND FEEDER SWITCHING AND INDICATING APPARATUS.

The booster outfit, built by the General Electric Co., consists of one positive and one negative dynamo, at each end of a common shaft, each capable of raising the e. m. f. of 1,200 amperes 60 volts. These boosting dynamos are driven by two 75 k. w., 240 volts, compound wound motors placed between the two dynamos, and so connected that either or both motors can be used at pleasure.

THE CONTROLLING ROOM.

At the rear of the battery room and adjoining the booster room is the controlling room, which contains, on the front wall, the four cell regulating switches, and on the rear wall the battery, booster and feeder switching and indicating apparatus.

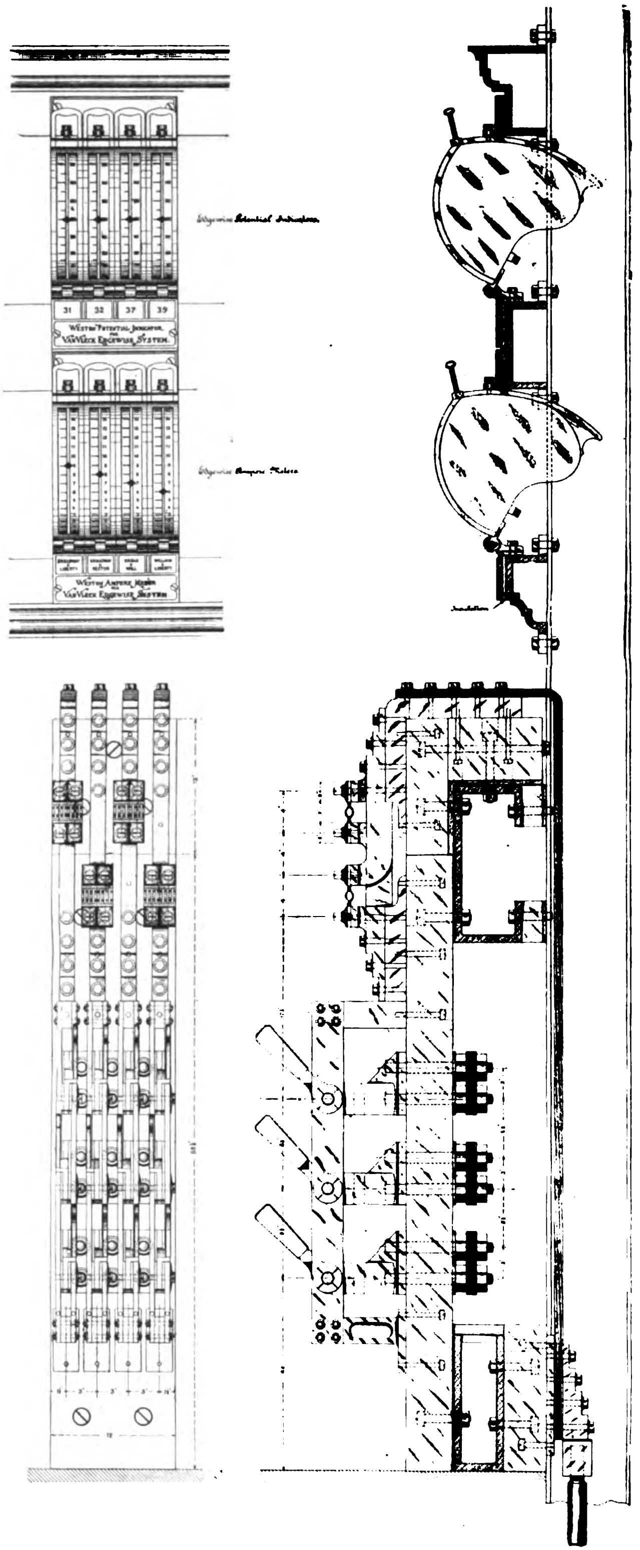

FIG. 10.—EDGEWISE FEEDER SWITCH AND INDICATING APPARATUS. FRONT AND SECTIONAL VIEW.

The general scheme of the battery, feeder and booster connections is shown in the diagram, Fig. 6, from which it will be seen that three main busses are employed, any one of which can be used to supply either the booster motors, the booster dynamos or any of the feeders, while the battery at the same time can be discharged on to either one of two busses, which arrangements permit of great flexibility in the operating of the plant. The cell regulating switches, of which there are four, embody several novel features, chief of which might be mentioned the movable dial adjacent to the operating handle, which indicates to the operator the particular end cell used on the charge or discharge. These dials are shown in the perspective, Fig. 11, and in the diagram, Fig. 7. Each regulating switch is of ample capacity to carry 1,500 amperes.

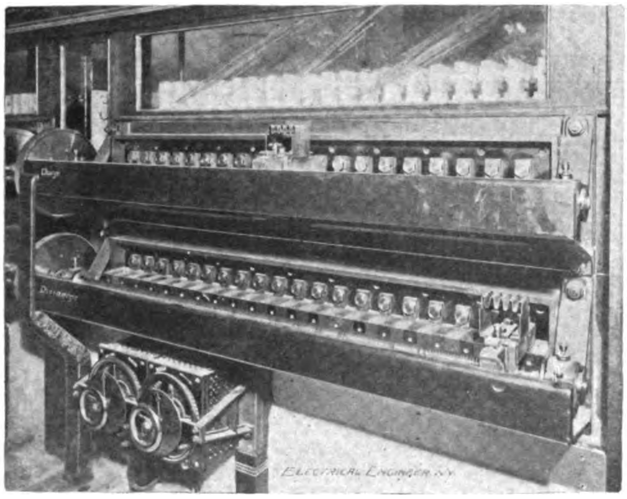

Fig. 11.—Cell Regulating Switches.

All of the positive and negative feeder, motor, booster and battery charge and discharge switches, with the volt and ampere indicating apparatus, located on the rear partition, are constructed on the Van Vleck edgewise system, which has resulted in a considerable saving of space, making the switchboard proper only 12 feet long, including the space required for a central desk. A front view and section of the apparatus for four 1,000 ampere feeders, occupying a width of 12 inches, is illustrated in Fig. 10, the switches and other apparatus for the attery and booster outfit, being exactly similar to the feeder apparatus. The engraving, Fig. 9, gives a clear view of the entire board. All of the circuits from the switches, with the exception of the feeder circuits, are provided with separate standardized copper shunts for the Weston ampere meters; while for the feeder circuits a portion of the cable has been used for this purpose. The connections between the switches and the feeder ends in the vault and to the booster outfit have been made with rubber-covered lead encased cable run through the tile ducts in the floor.

In addition to the feeder and battery controlling apparatus there is employed additional apparatus for the measuring of the potential at the feeder ends and of the battery cells and for the operating of the controllable junction boxes inserted in the trunk feeders running to the Duane street station, permiting the trunk feeders to be connected or disconnected at will from the underground street mains directly from the operating room. A general plan of the arrangement of cells, booster room, operating room, etc., is shown in Fig. 6. This shows the connection between the cells and connections from the end cells to the cell regulating switches.

VENTILATION.

The battery room is ventilated by means of a duct passing overhead through the operating room and discharging into the main smoke flue of the building. The ventilation through this duct can be assisted, when necessary, by means of a fan placed in the duct and operated by a one-quarter horse power motor external to the duct.

Though this battery station has been in operation barely a month, the results already obtained with it more than bear out the anticipations of the company, and it will very likely lead to the installation of other similar equipment as the demand for current in the outlying districts increases.

THE MACINTIRE ENCLOSED ARC LAMP.

In a brief note in our issue of February 24 we drew attention to the new departure in enclosed arc lamps effected by the International Arc Lamp Company, whose offices and works are situated at the corner of Houston and Mercer streets, New York.

The first installation of these lamps has been placed in the restaurant of J. Kamsler, at 713 Broadway, New York, and their appearance and effect are admirably shown in the accompanying engraving, Fig. 1.

As will be seen, the lighting is done by six Macintire lamps attached to the ceiling and projecting downward only 19 inches, of which 3 inches are taken up by the canopy. The bulb enclosing the arc is shaded from below by a regular incandescent lamp shade, while surrounding the bulb is a ring of crystal prisms carried by an ornamental canopy. The lamps take 80 volts and are run from the Edison mains. The resistance in circuit with each lamp is mounted on the switchboard and does not encumber the lamp as is usually the case. The entire effect of these lamps is highly artistic.

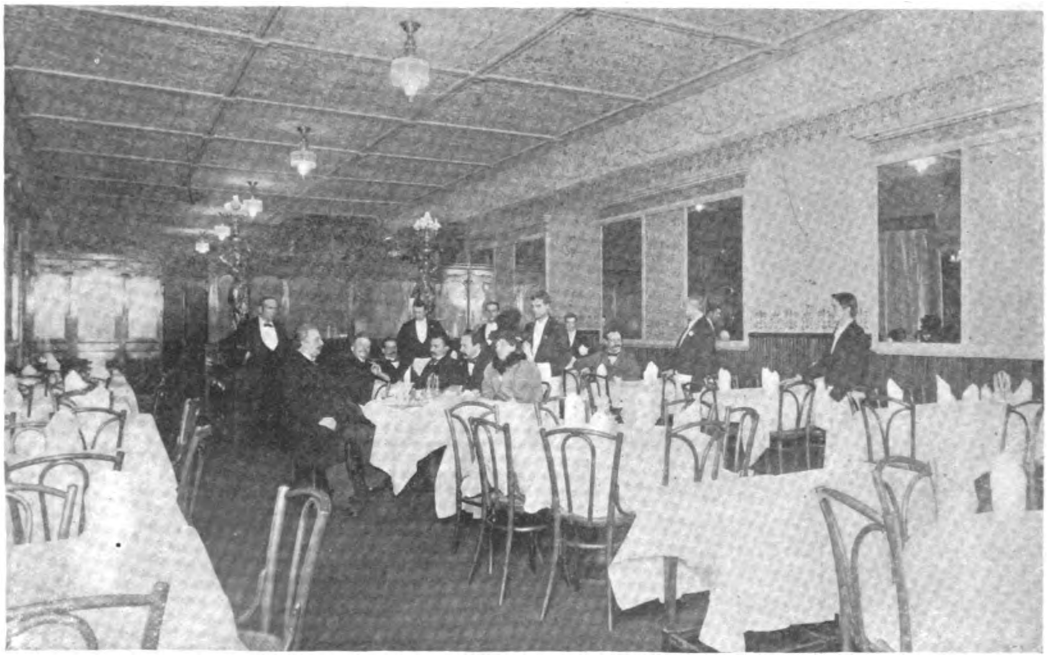

Fig. 1.—Macintire Enclosed Arc Lamp in New York Restaurant.

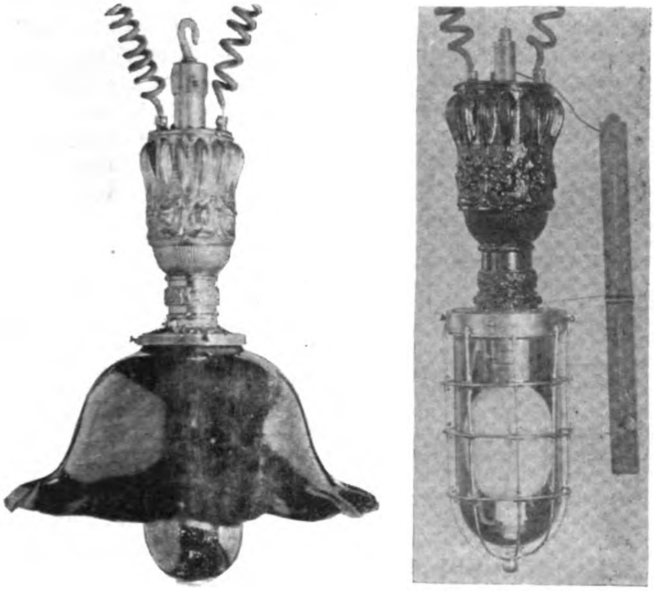
A good idea of the construction of the lamp will be had from the engraving, Fig. 2, which shows one style in an enlarged view, intended for interior illumination. The short length of the lamp adapts it particularly for the illumination of apartments, stores, etc., and especially for ship and marine lighting, where there is very little head room. The marine type of lamp is shown in Fig. 3, and, as will be seen, it occupies scarcely more space than an incandescent lamp. The bulb is protected by a grating and the lamp can be easily shifted from one position to another when necessary.



FIGS. 2 AND 3.—MACINTIRE ENCLOSED ARC LAMPS.

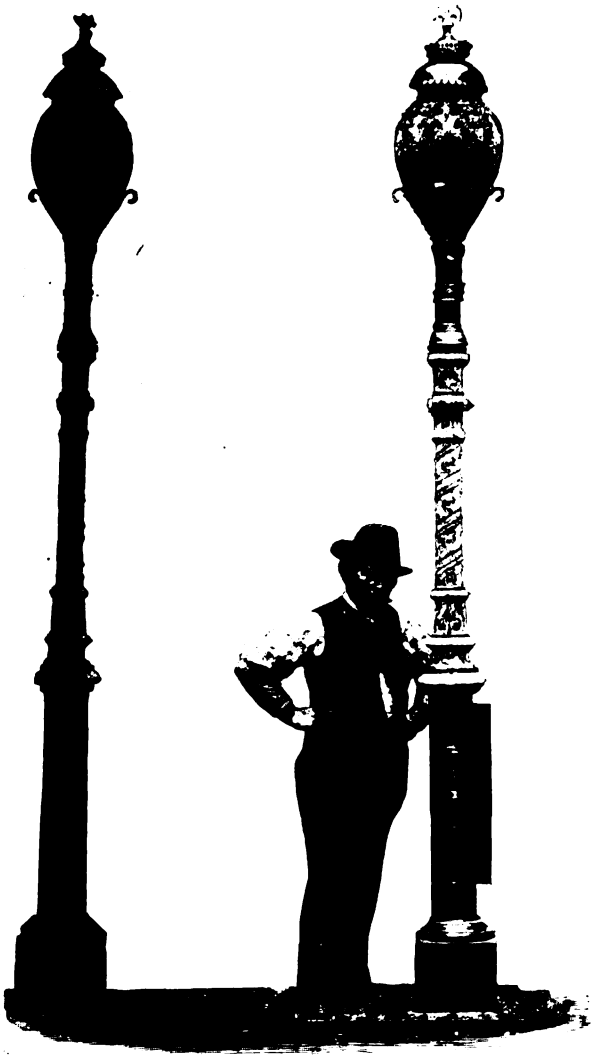


FIG. 4.—MACINTIRE STREET ARC LAMP POST.

In addition to the lamps for interior illumination, Mr. G. R. Macintire, the inventor, has designed a special type to be used in connection with a street lamp post. This is shown in the engraving, Fig. 4. The lamp is mounted on the top of the post, but the lamp mechanism is placed in the lower section near the ground and can be got at by opening a cover in the post, as shown in the post at the right. A slender rod connects the mechanism with the carbons in the bulb and regulates their position with the greatest nicety. Several of these highly ornamental Macintire lamp posts have been installed in this city. They lend themselves particularly to the illumination of the entrances of stores and public buildings, and for street illumination generally. There is little doubt that they will meet with appreciation by the lighting fraternity.

MISCELLANEOUS

FOREIGN DUTIES ON ELECTRIC MACHINERY AND LAMPS.

THE following statement, showing the rates of import duty leviable on dynamo-electric machinery and electric lamps in the principal European countries, has recently been prepared:

Countries and Tariff Classification.	Rates of Duty—United States Equivalents.
Austria-Hungary:	
Dynamo-electric machines	$1.23 per cwt.
Electric lamps	$12.37 per cwt.
Belgium:	
Dynamo-electric machinery—	
The duties are assimilated to those on machines and machinery of all kinds which are—	
Machinery of cast iron	19¼ cents per cwt.
Machinery of wrought iron or steel	39 cents per cwt.
Machinery of copper or other metal	$1.18 per cwt.
Electric lamps	10 per cent. ad valorem.
Bulgaria	10½ per cent. ad valorem.
Denmark:	
Dynamo-electric machines	57 cents per cwt.
France:	
Dynamo-electric machines weighing—	
5,000 kilograms and more, containing at least 50 per cent. of cast iron	$1.18 per cwt.
5,000 kilograms and more containing less than 50 per cent. of cast iron	$1.99 per cwt.
From 2,000 to 5,000 kilograms, containing at least 50 per cent. of cast iron	$1.78 per cwt.
From 2,000 to 5,000 kilograms, containing less than 50 per cent of cast iron	$1.99 per cwt.
From 1,000 to 2,000 kilograms	Do.
From 50 to 1,000 kilograms	$2.96 per cwt.
From 10 to 50 kilograms	$7.91 per cwt.
Conductors for dynamo-electric machines and detached pieces, such as metal coils, surrounded by insulated copper, worked parts of copper weighing less than 1 kilogram, numbered and marked, fitted together or not for electric machines weighing—	
More than 2,000 kilograms	$3.47 per cwt.
From 1,000 to 2,000 kilograms	$3.95 per cwt.
From 200 to 1,000 kilograms	$4.44 per cwt.
From 1 to 200 kilograms	$5.94 per cwt.
Less than 1 kilogram	$7.42 per cwt.
Electric lamps—	
Incandescent lamps of glass—	
With their mountings	$34.60 per cwt.
Not with mountings	$69.22 per cwt.
Arc lamp (regulators)	$5.94 per cwt.

Germany:	
Dynamo-electric machines (so far as they can not be described as "Lokomotiven" or "Lokomobilen")—	
Preponderating material being of cast iron	37 cents per cwt.
Preponderating material being of wrought iron	62 cents per cwt.
Preponderating material being of other common metal	98½ cents per cwt.
Electric lamps—	
Incandescent lamps of glass in conjunction with other materials so far as the same can not be classed as hardwares, etc., with the exception of cases in which platinum wire is used	$2.96 per cwt.
Electric arc lamps and other electric lamps	According to material of which composed.
Greece:	
Dynamo-electric machines	Free.
Electric lamps—	
If of glass	$7.69 per cwt.
If of plain porcelain	$3.89 per cwt.
If of porcelain, inlaid, colored, or gilt	$15.57 per cwt.
Holland:	
Dynamo-electric machinery	Free.
Electric lamps and appliances for electric lighting not forming part of the machinery	5 per cent ad valorem.
Italy:	
Dynamo-electric machines—	
Weighing up to 1,000 kilograms	$2.47 per cwt.
Weighing more than 1,000 kilograms	$1.58 per cwt.
Detached part of dynamo-electric machines	$2.47 per cwt.
Electric lamps—	
Of bronze, brass, steel, or iron	$2.96 per cwt.
Norway:	
Dynamo-electric machines	Free.
Electric lamps—	
Portugal:	
Electric apparatus and machinery for whatever purpose	30 per cent. ad valorem.
Electric lamps—	
Roumania:	
Dynamo-electric machinery	Free.
Electric lamps	$4.94½ per cwt.
Russia:	
Dynamo-electric machines of all kinds	$3.34 per cwt.
Electric lamps	$14.34 per cwt.
Spain:	
Dynamo-electric machines	$1.82 per cwt.
Electric lamps, chargeable as ordinary lamps, according to material of which composed, as follows—	
Of copper	$12.17 per cwt.
Of cast iron	84 cents to $1.73 per cwt.
Of wrought iron	$2.96 to $3.57 per cwt.
Of tin plate	$4.95 per cwt.
Of other common metals	$3.71 to $4.44 per cwt.
Of glass and crystal	$4.95 to $10.88 per cwt.
Of earthenware	$3.71 to $11.84 per cwt.
Of porcelain	$5.19 to $11.06 per cwt.
Sweden:	
Dynamo-electric machinery	10 per cent. ad valorem.
Electric lamps	$20.60 per cwt.
Switzerland:	
Dynamo-electric machines	39 cents per cwt.
Electric lamps	59 cents per cwt.
Turkey	8 per cent. ad valorem.

BUFFALO proposes to have a special Niagara power celebration next August at the time of the Grand Army of the Republic Encampment. Mr. C. R. Huntley has hold of the electric end of it, and it is said that Mr. Tesla will probably furnish some original ideas for interesting electrical effects that will render the occasion memorable.

THE HÆMOGLOBIN CARBON CELL.

BY WILLARD E. CASE.

IN order to correct any false impression which may have arisen in consequence of the sensational articles which have appeared in the daily newspapers, I desire to say that the haemoglobin experiment, shown by me in the lecture delivered before the New York Electrical Society,[1] was simply done for the purpose of showing that blood absorbed oxygen and gave it up to reducing agents; then on exposure to air it would absorb more oxygen and give it up again, and so on. I did not have a haemoglobin cell present, as some of the sensational newspapers said. During the discussion I was asked by one of the members if haemoglobin would give a current, and I answered yes, as I had before determined. So I placed a piece of platinum and a piece of carbon as electrodes in the haemoglobin solution and showed the audience that the voltmeter was affected. Now, we all know that two dissimilar substances give an electromotive force, even in water, and I might say even in pure water. In this experiment there might have been some iron in the carbon. It will be borne in mind that it was during the discussion that this came out at the request of one of the members, though I had known the facts before, but preferred to say nothing about them, as I did not wish to be placed in the light of bringing out a new cell before I had more fully investigated it.

Immediately following the lecture, however, I set about to make a test, the results of which were as follows: (1) Carbon stick and platinum in the haemoglobin solution gave .06 volt. (2) Took the stick out and exposed it to air, and then tried again and got .07 volt. (3) Added potassium hydrate solution, and the highest e. m. f. obtained was .08 volt. (4) Platinum and animal charcoal gave 0.12 volt. (5) The potassium hydrate solution alone gives only about .01 to .02 volt.

This shows that the haemoglobin does act as a carrier of oxygen and oxidizes the carbon. Bubbling air through does not help the process; that is, the haemoglobin is so fully oxidized that an excess of air is of no value. Of course, when the haemoglobin becomes reduced, then it will absorb more oxygen from the air. With different forms of carbon we get different voltages. This haemoglobin solution, however, would not be of any practical use, as it decays in two or three days.

What I said in my lecture I adhere to and believe I can maintain, but I cannot be held responsible for the writings of unscientific reporters of the daily press.

ELECTRICITY AND ELECTRICAL ENGINEERING IN CHINA AND JAPAN.

BY R. VAN BERGEN.

THE building of the electric street railroad in Shanghai marks the inauguration of a new era for China. Her conservatism and reactionary principles have been steadily undermined for the past half century, but the spirit of self-preservation now impels her on the march to progress. The Japan-Chinese war woke up the sleepy mandarins, who had been taught that China was the Middle Kingdom and that all nations were naturally tributary to her; but Li Hung Chang's trip around the world has given the impetus necessary to open up immense natural resources and to inaugurate improvements.

Since his sojourn in the United States, the writer has been asked frequently about the opportunities in China and Japan for electrical engineers and for the sale of electrical apparatus. As to the last named country, the chances for both are exceedingly slim, and it would be wrong to advise a young man to go to the Mikado's Empire for the purpose of bettering his condition. Japan is still adhering to her old plan of sending out bright, industrious, young men to learn practically, as well as theoretically, whatever new discoveries are made. Scientific books as well as periodicals find earnest readers, and her colleges and universities are fully up to the times. She is gradually discharging such of the few foreign employés as are left, and wholly declines engaging any one but natives, except in very exceptional cases. After Americans had introduced electric lights and the telephone in Tokyo, native engineers have established similar plants in the large cities of the Empire, and, although the result was not always satisfactory in the beginning, they have overcome all difficulties, and now furnish a highly satisfactory service. While the Japanese decline to employ foreigners, they have also prohibited the use of foreign capital. Under the present treaty, foreigners cannot own real estate, except in the few square rods of the foreign concessions in the open ports, nor can they own shares in a Japanese enterprise. Even Japanese bonds are inalienable to foreigners. Hence the opportunities to invest capital are exceedingly slim. The above, strictly correct statement, will demonstrate satisfactorily that Japan offers no opportunity either for ambitious young men or for the trade.

---

[1] The Elec. Eng., March 3.

It is quite another case in China. As is well-known, the Emperor is a mere figurehead, the real power being pretty evenly divided between Li Hung Chang, the Viceroy of Pe-chili, and Chang Chih Tung, the Viceroy of Hupeh. Some five years ago these rivals agreed that it was time to start improvements, but Li Hung Chang favored the introduction of foreign capital, whereas Chang Chih Tung believed in imitating the example of Japan. The latter, therefore, was sent to Nanking, and spent enormous sums of money in establishing railroad shops at Hankow, without any results. Li Hung Chang, upon his return, succeeded in convincing the privy council, not only of the immediate necessity of beginning improvements, but of enlisting foreign capital to carry them out. This capital is furnished, probably by Russian financiers, who keep an eye on future acquisition of territory. But the skill and ingenuity employed is American.

It is impossible to form a conception of the immensity of the Empire and of its resources, and since word has gone forth that improvements must be made, the anti-foreign feeling, always induced by the mandarins, is rapidly subsiding, if it has not wholly disappeared. The government is taking the initiative in introducing improvements. The palace of the late Empress Dowager was furnished with electric lights prior to her death, and it is rumored that the Yellow City, the residence of the Solitary Man, will soon be likewise provided. Li Hung Chang distinctly favors Americans. Aside from the goodwill he experienced here, he was acute enough to see that our inventions were the best, the ability of our engineers the greatest. And it must not be forgotten that for many years he has been on most intimate terms with a United States Consul of Tientsin, who resigned this office to accept the position of tutor to Li's favorite son, and who still occupies a position in Li's household.

There is, therefore, no small opening for American ingenuity and enterprise in China, and still it would scarcely be advisable to proceed there on speculation, unless one were provided with solid letters of introduction, and with the means to live, at least for a year. The passage to China is expensive, notwithstanding the number of steamboat lines plying between the Pacific coast and Shanghai.

That city is in reality a republic, the government being conducted by the municipal council, which is largely English. It is, however, the port where the first stop is made, and in the summer season, that is from March to October, steamers leave for Tientsin almost daily. This last named city, the residence of Li Hung Chang, is also the seat of government, so far as concessions or appointments are concerned, and as Li is easily accessible, and perfectly willing to listen to and entertain suggestions, the difficulty is fairly overcome when Tientsin is reached.

China, being a silver country, the cost of living is very moderate, hotels charging about $3 a day Mexican. Such is the rate in the Astor House in Tientsin, and in the Hotel des Colonies in Shanghai. But the best way by far would be to communicate by letter, either direct to Li Hung Chang, whose secretary and interpreter is sure to attend to the matter, or through the intervention of the United States Consul, or some American business house. Of the latter, the China and Japan Trading Company, whose headquarters are in this city, is the oldest and most influential. The time is propitious because, although England is alive to every commercial enterprise and her business houses have agents in every open port of China, the intended improvements are as yet only conceptions, although a beginning will be made shortly. The building of the railroad between Te-tschau and Pekin, a distance of 700 miles, will begin on the 13th of this month. The construction is in charge of American engineers. Other improvements, such as the building of the electric road between Shanghai and Woosung, a distance of 12 miles, will be initiated this year.

SUBWAY EXPLOSION IN BOSTON.

Owing to a bad leakage of gas into one of the subway excavations in Boston last week, a serious explosion occurred at the corner of Tremont and Boylston streets on March 4 about midday. No authentic explanation is given of the explosion, but it is said that it may have been due to the sparking of one of the street car motors that pass every second; but it was far more likely due to the dropping of a lighted match or cigar or cigarette. Complaints had been made during the morning of the gas leak, and just before the explosion people had been telephoning to the gas company. Be this as it may, one of the passing cars was blown in two, other adjacent vehicles were damaged, six people were killed outright and fifty were injured. Windows and stores in the vicinity were badly shattered, and it is feared that some of the foundations were shaken.

LETTERS TO THE EDITOR

POWER PLANT ENGINEERING ON STEAM RAILROADS.

I NOTICE in your issue of Feb. 24 a short article on "Electric Locomotion in New England," which contains some remarks made by the president of the N. Y., N. H. & H. R. R. before the Connecticut Legislature, opposing a proposed competing electric line.

That the N. Y., N. H. & H. R. R. Company are "deep" in the transition work of converting a great system from steam to electricity is apparent to all competent electrical engineers, and the railway company will find themselves "deeper" yet, unless they change their methods. It is also apparent that much of their work is in truth "experimental." It does seem to an outside engineer that a powerful corporation, which can command, if it will, the best electrical and steam engineering talent in the world should actually retard the progress of the larger and more important electric railway work, while professing to advance it. In many ways the Nantasket construction is very crude compared with overhead construction of five years ago. The engineers of the railway company have claimed that the overhead trolley is not satisfactory for heavy loads and high speeds, judging from their Nantasket experience. It will, I think, be admitted by all competent engineers that this is largely due to the faulty construction and that it is possible to operate, at as high a rate of speed and with as heavy loads, by means of a properly constructed overhead trolley system.

These railway engineers then advocated a third rail and installed a considerable length of it, but they have it alive continuously for its entire length, a source of leakage in bad weather and a danger at all times.

Moreover, in their power stations this railway company have installed the tubular or older form of boiler in numerous small units, instead of rapid steaming modern safety boilers, in a few large units, and operating at a high pressure. Modern engineering skill and observation has long ago proved the economy and wisdom of the latter type and yet, even in the latest station of the N. Y., N. H. & H. R. R. Company, now being completed at New Britain, the boiler plant is to consist of ten comparatively small units! Furthermore, the same company are installing in their new passenger depots this same tubular boiler for heat and power, instead of safety sectional boilers, although scarcely a day passes without a fatal explosion of one or more tubular boilers occurring in some part of the country.

These points of retrogression can be multiplied, but I do not wish to take up your valuable space with further criticism of the engineering skill of President Clark's advisers. I will conclude with the hope, which must be shared by many other and more competent engineers than myself, that the N. Y., N. H. & H. R. R. Company may speedily awake to the fact that they are behind the times and should "hustle," not only to keep up with the procession, but to be at the head of it.

"ELECTRICAL ENGINEER."

New York, Feb. 27, 1897.

MENTAL ACTION AND THE ETHER.

In regard to the subject matter of your editorial on Prof. Crookes and brain waves, it is very improbable, as I pointed out long ago, that brain action is unaccompanied by wave disturbances in the ether. It is only a question as to their intensity and capability of awakening thought in a recipient brain. This, as I understand it, is the real question at issue; not whether there be brain waves, but whether they be capable of accounting for the phenomena of telepathy. I still see no reason to change my opinion as to the possibility of this action.

VOL. XXIII. NEW YORK, MARCH 10, 1897. No. 462.

" ACCIDENTS. "

EVER since electrical distribution on a large scale came into vogue a noteworthy proportion of the loss of life and property which has followed its introduction has been ascribed to "accident," that conscience-easing term which has been so much abused in the past. That there may be accidents in the true sense of the word, we do not propose to deny, but the time has gone by when the destruction of an entire central station ought to be ascribable to any cause short of an earthquake. And yet an "accident" due to gross carelessness initially, is given as the cause for the total destruction by fire of the Mount Vernon street power house of the Philadelphia Traction Company.

According to newspaper reports the primary cause of the "accident" which led to the destruction of the station was the fouling of the chain of a traveling crane with one of the running dynamos. We can very well see how such an accident, or rather such gross carelessness, might have been followed by the wrecking of the machine interfered with, but we confess our inability to conceive the combination of circumstances which led to the disaster that followed. Given that the dynamo in question had been short circuited, the safety devices provided for just such emergencies ought to have been adequate to take care of the abnormal load. If it be argued that it was not a case of inoperativeness of safety devices, but the throwing around of molten metal on the oil-soaked floors that resulted in the conflagration, then still less does this constitute, in our estimation, a valid excuse. The management of a central station which allows oil to accumulate on its wooden floors in these days of cheap concentrated lye, is either incompetent or worse. Besides, a wooden floor is bad engineering, to begin with. It is just such incidents as these that are apt to set at naught all the ingenuity and care bestowed on his work by the electrical engineer. We trust that for the benefit of the entire fraternity the Philadelphia disaster may be thoroughly investigated, and the blame fastened where it belongs.

Another so-called "accident," which resulted in fearful loss of life, was the gas explosion over the new Boston subway last week. This is asserted to have been caused by ignition, due to a spark from an electric car passing over the subway; but it is evident that a lighted cigar stump might be equally accountable for the result. Granted that it was due to an electric spark, the fact that a leakage of gas had been detected some time before the accident, and the gas company urgently notified of the fact, makes it unfair to lay the blame in any way upon electricity, which is now the general practice when no other cause can be readily assigned to account for mysterious fires and explosions, such as the one referred to. We hope that Mayor Quincy will carry out his proposed idea of instituting a rigid investigation of this deplorable "accident."

A GENERAL LAMP TESTING BUREAU.

A SHORT time ago in commenting upon the steps which had been taken in Germany towards the establishment of a bureau for testing incandescent lamps, organized for the benefit of central stations and other consumers of lamps, we drew attention to the advisability of establishing a similar bureau in the United States, where such an institution would evidently be of far-reaching importance, in view of the enormous development which electric lighting has attained in this country. A proposition of this nature seems so natural that it is strange some action has not been taken before this in the matter; but we are glad to know that active plans are under way, looking towards the establishment of such a bureau, and that President Nicholls, of the National Electric Light Association, has taken up the matter with characteristic energy. In his third interim report to the National Electric Light Association, which we print on another page, will be found the preliminary plan for such a bureau, which ought to command the immediate attention of all users of incandescent lamps. The plan being merely tentative, the actual tests to which lamps should conform are not given, but these will not be difficult to fix when the time for actual consummation of the plan arrives. In looking over the plan we notice that the manufacturer is subjected to penalties for deficiency in the quality of his products, which is quite proper; but no provision is made for compensating the manufacturer for qualities in his lamp exceeding the required standards. In this respect the present plan differs from the German, in which the manufacturer receives a bonus commensurate with the excess above the standard. Whether or not such a bonus is expedient is a matter which may well be open to debate, but it seems to us that it would be an eminently fair arrangement, and we see no way in which it could work any hardship, as the consumer would in every such case be getting the full value of his money. It is not generally known, but we understand that a bureau of this nature is now in actual operation, carried on by a certain number of central stations in the United States, and that its work has proved eminently satisfactory to all concerned, including both the manufacturer and the user. We can see where great benefits will accrue to the entire art from the work of such a bureau established by the National Electric Light Association, and trust that no efforts will be spared to bring about its early establishment.

CONDUIT TRACTION IN NEW YORK.

THE Metropolitan Traction Company has now confirmed the announcement of its decision to adopt electricity on several of its lines. Out of 165 miles of road it will have 43 operated electrically, and the method will be, as stated, that of the underground conduit. Mr. J. D. Crimmins, speaking for the company, says that the cost of running a car one mile, including everything but the fixed charges on the investment is, with electricity, 9 to 9½ cents; with compressed air, 12 to 14 cents, and with the cable about 18 cents. He intimated, therefore, that even the present cable systems of the company would have to go. A curious misapprehension appears to exist in some quarters as to the effect of the underground system on adjacent gas and water pipes. Because, such pipes sometimes go, with badly handled trolley systems, it is inferred that the results must be inevitable, and worse, when both wires are under the surface and near the pipes. The public is already learning, however, that from the very nature of things the underground system is safe company for the neighboring pipes. It may be expected that in its new work the Metropolitan Company will improve upon its Lenox avenue line. Repairs have been quite frequent and costly. Moreover, it may be expected that no further trial will be made of brick paving around the tracks. The condition of this paving on the Lenox avenue line, although the road is still so new, is pitiable. It may fairly be described as a sad ruin.

WITH THE opening of spring weather, the bicyclists are beginning to make their appearance in great numbers and it is noticeable that a good many of them appear to be furnished with electric lamps. The old oil lamp is still far from satisfactory, and there would seem to be a good market here for electricians to work up, especially for those who are in touch, as many of them are, with the bicycle trade. Some of the lamps on the market this season strike one as practical and successful.

ROENTGEN RAYS

THE EFFECT OF X-RAYS ON THE HAIR.

BY FREDERICK S. KOLLE, M. D.

DAILY, the reports of the pathological conditions caused by exposure to the Röntgen rays, meet the eye; in fact, there is much smoke and but little fire. The usual reports refer to dermatitis, an inflammatory condition of the skin, resembling sunburn, which is readily overcome by judicious treatment, but differing somewhat in its stubborn nature to be influenced by such remedies as readily bring about a recovery of a dermatitis when due to other causes.

Another peculiar result is the falling out of the hair about the face or head, when exposed to the rays. I wish to present a typical case of the latter, which is not only of interest, but of considerable value to the radiographer, who may at any time be threatened with legal proceedings to recover damages for such injuries, which are but temporary and where recovery is complete.

The patient was a boy thirteen years of age. Through my earnest wish, expressed to his parents, I was permitted to make a radiogram of his entire body, on my assuring them that no harm would come to him. The same boy had sat for some of the pictures exhibited by me at the National Electrical Exhibition in New York in May, 1896. He came to my laboratory during the week of Oct. 19 to 24, 1896, and on Oct. 21 I made a radiogram of his head. The exposure was one of forty minutes, made in the usual way, with a Thomson double focus tube. The distance between the tube and skull was about 18 inches, as I passed an 18-inch desk rule between the tube and head at the time with perfect ease. He slept during the entire time of the exposure, and I had to tap him on the head to arouse him, and he was surprised to find that the whole time had flown by. This was the only radiogram made that day, and as I obtained such a good result, it was not necessary to make another of the skull.

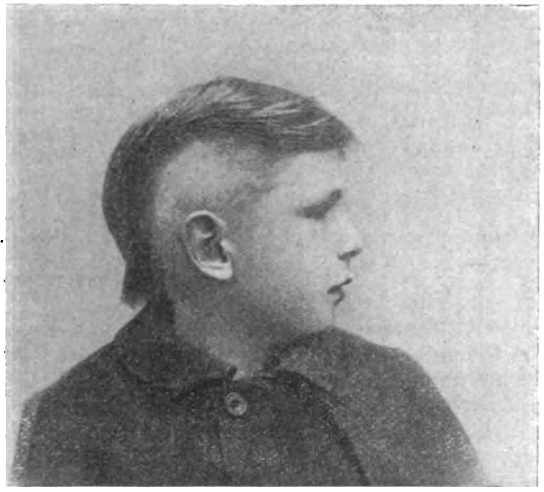

FIG. 1.—APPEARANCE OF BOY, NOV. 9, 1896.

The radiogram of the entire body was completed in the four sections necessary, and my little friend disappeared, until, on Nov. 9, when he came to my office and showed me his head, where, to my great displeasure I saw a large area of hair missing from the side of the head exposed to the vacuum tube, as shown by the illustration, Fig. 1, which is a reproduction of a photograph made on that day.

The boy gave no history of pain, itching or other signs of inflammation. All he knew is that, on the night previous the hair had suddenly fallen out. The depilated area corresponds to the side of the head exposed to the tube, and as another such case had been reported in Chicago, I came to the conclusion that this was a similar case; that the depilatory cause was none other than this unknown force, emanating from a charged vacuum tube. A peculiar fact to be noted is that the hair all fell out at once. The integument or scalp appeared bald, somewhat elevated and slightly œdematous. There was no redness; sensibility was not impaired, the bald patch was regular, and scaling was absent.

His hair was cut, and stimulating and hygienic treatment was at once commenced. The œdema, or watery condition disappeared in a few days and fine, downy hairs began to show themselves. These were again cut when they had reached a length of one-eighth of an inch.

It seems to me that it would be well to treat the area exposed to the rays at once after long exposure, say 35 to 40 minutes, at least, hygienically, with the hope of stimulating the nerve or follicle to nourish its individual hair, whatever the cause of the alopecia or baldness may be. The head should be washed once a week for a time and thoroughly dried and daily a non-irritating oil should be used containing tincture of nux vomica, half a drachm to the ounce, or tincture of cantharides, one drachm to two ounces of the oil, adding a little oil of lavendula, to cover the oily odor. Soap should, by all means, be avoided, unless the hair is thoroughly dried after its use and the above oil used.

This treatment was continued quite regularly up to the present time. The new hair, having been cut three times, was allowed to grow thereafter, and is now (March 2) about three-fourths of an inch long, as shown in Fig. 2. The new hair is of a somewhat lighter color than the hair of the head not affected, owing to a lack of pigment; but I notice that it is daily growing darker, being most marked about the roots of the hair. The shaft of the individual and new hair is not as strong as the old hair, but I find here and there strong hair interspersed about the area of new growth.

I beg to demonstrate by describing this case that the nerves of the follicles and the minute blood-vessels supplying the hair are not destroyed by the rays as has been supposed heretofore, and therein the action of the rays differ from the depilatory action of the direct electrical current, where the entire follicle is destroyed. The same treatment, as is herein described, can be employed in the treatment of alopecia about the face, where the hair has fallen out as a result of exposure to the X-rays usually occurring to the operator himself.

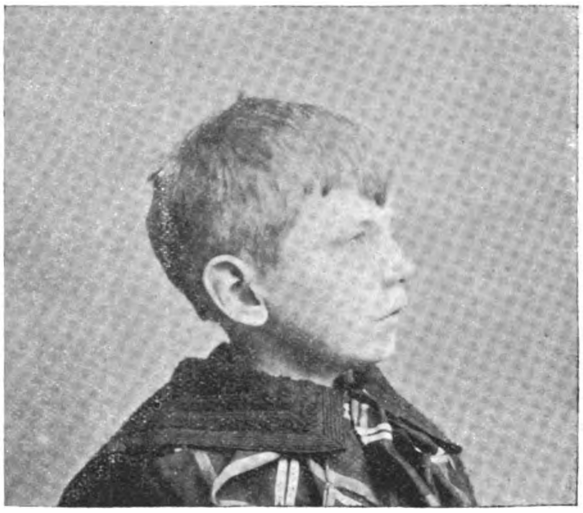

FIG. 2.—APPEARANCE OF BOY, MARCH 2, 1897.

I may here mention that, although I have made over thirty radiograms of the human head, where the exposures varied from 32 to 60 minutes, no symptoms of baldness resulted, as in this case, although the age and the fineness of the boy's hair may have been an important factor in bringing about the result shown.

LENARD AND ROENTGEN RAYS.

BY EDWARD P. THOMPSON.

THE contents of a communication received by the writer from Dr. Philip Lenard of Heidelberg, may be of interest as shedding some light on the relations between Lenard and Röntgen rays. The communication was called forth by my treatment of the external radiations from a discharge tube (Crookes tube), and especially my discussion of his own researches, which were originally published in several foreign proceedings of societies, and in foreign languages, some of them being published by Berlin Akad. Jan. 15, '93, Wied. Ann. Jan. '94, Vol. LVI, p. 225. Wied. Ann. Vol. LI., p. 259, and papers and articles of 1895 and 1896. Translations of these and other papers, discussions of Lenard's results by other investigators, and Lenard's latest theories, were considered in my own language under about twenty headings, setting forth in a classified manner the various facts, principles, and theories relating to external cathode (or Lenard) rays, in the book, "Röntgen Rays, and Phenomena of the Anode and Cathode."

Dr. Lenard, in stating that "We agree in all you have said on my experiments in the text of your book," discloses succinctly his present valued opinions on three points in this English letter. One of his remarks seems to indicate that he does not agree in all points with Prof. Röntgen.

In my book, I stated: "A remarkable occurrence was the accomplishment of the discharge at a much greater distance than that at which phosphorescence was exhibited. See also experiments of Röntgen, who suggested that Lenard had to do with X-rays in his experiment, but thought they were cathode rays. The maximum distance for the discharge was 30 cm., measured normally to the aluminum window. He (Lenard) admitted that the experiment was not carried far enough to know whether the effect was due to the action of the cathode rays upon the surrounding air, or upon the plate." The above related experiments were performed, it should be remembered, before Röntgen 's discoveries. Dr. Lenard now says, as stated in the letter referred to: "I do not think the electric (discharging) actions at a great distance from the window of my apparatus due to Röntgen rays, because I have convinced myself in the meantime that these latter rays are only present in minute traces, and that there is another explanation of the fact observed. The air is made conducting by the deflectible cathode rays near the window, and afterwards extends to part further apart, whilst retaining its conducting property."
